- #### 4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)

Alias names for interfaces, if used, appear in the headings for the Interface Pair View or what used to be called the Section View.

Multiple interfaces or ANY interface can be added to a firewall policy. This feature can be enabled or disabled in the GUI by going to the **System > Feature Select** page and toggling **Multiple Interface Policies**.

When selecting the Incoming or Outgoing interface of a policy, there are a few choices:

- The **ANY** interface (choosing this will remove all other interfaces)
- 1 A single specific interface
- 1 multiple specific interfaces (can be added at the same time or one at a time)

The GUI is intuitive and straightforward on how to do this. Click on the "+" symbol in the interface field and then select the desired interfaces from the side menu. There are a couple of ways to do it in the CLI:

1. Set the interfaces all at once:

```
config firewall policy
edit 0
set srcintf wan1 wan2
end
```

2. Set the first interface and append additional ones:

```
config firewall policy
edit 0
set srcintf wan1
append srcintf wan2
end
```

5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

- **LEARN** - collects information about the traffic for future analysis
- **IPsec** - for using with IPsec tunnels

Because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled)

The NAT setting section is affected by whether or not Central NAT is enabled.

If Central NAT is enabled, the only option in Firewall / Network options will be whether to enable or disable NAT. The rest of the NAT parameters will be set in the Central SNAT page.

If Central NAT is disabled, there are two additional settings in the Policy configuration page.

11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the **+** icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the **+** icon next to the **Search** field is a shortcut for creating a new IP Pool.

Security Profiles

13. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.
14. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The **+** icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**
- **VoIP**
- **ICAP**
- **Web Application Firewall**
- **Proxy Options**
- **SSL/SSH Inspection**

Logging Options

15. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

16. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
17. Toggle whether or not to **Enable this policy**. The default is enabled.
18. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the Log Violation Traffic setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

Settings if the LEARN action is selected

To get more information on the **LEARN** option, read the Learning mode for Firewall policies topic in [What's new for Firewall in 5.6](#)

Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled). Unlike the **ACCEPT** option, whether or not Central NAT is enabled or disabled does not affect this settings options.
11. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
12. Toggle whether or not to **Enable this policy**. The default is enabled.
13. Select the **OK** button to save the policy.

Settings if the IPsec action is selected

VPN Tunnel

10. For the VPN Tunnel field, use the drop down menu to select the VPN tunnel that you want the policy associated with.
11. Toggle the sliding button to enable or disable the option to **Allow traffic to be initiated from the remote site**

Security Profiles

12. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**

- VoIP
- ICAP
- Web Application Firewall
- Proxy Options
- SSL/SSH Inspection

Logging Options

13. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

14. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
15. Toggle whether or not to **Enable this policy**. The default is enabled.
16. Select the **OK** button to save the policy.

IPv6 Policy

To configure a IPv6 policy in the GUI

1. Go to **Policy & Objects > IPv6 Policy**

The right side window will display a table of the existing IPv6 Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Make sure the policy has a name in the **Name** field

By default, a policy is required to have a name, but it is possible to toggle this requirement on or off in the CLI, or in the GUI if you have first enabled the GUI option in the CLI.

3. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.

6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Set the NAT parameter by toggling the slider button. (gray means it is disabled)
11. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected:

- An additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.
- An additional option to **Preserve the Source Port** will appear as a toggle option. If the slider button is grayed out it is disabled.

Security Profiles

12. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.
13. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **Application Control**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**

- VoIP
- ICAP

Logging Options

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
15. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the **Log Violation Traffic** setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

NAT64 Policy

To configure a NAT64 policy in the GUI

1. Go to **Policy & Objects > NAT64 Policy**

The right side window will display a table of the existing NAT64 Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
 3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
 4. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. The source in this case is an IPv6 Address object of the initiating traffic. When the field is selected a window will slide out from the right. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source Address** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)

7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
8. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv6 to IPv4, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.

12. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
13. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
14. Toggle whether or not to **Enable this policy**. The default is enabled.
15. Select the **OK** button to save the policy.

Settings if the **DENY** action is selected

Enable the Log Violation Traffic setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

NAT46 Policy

To configure a NAT46 policy in the GUI

1. Go to **Policy & Objects > NAT46 Policy**

The right side window will display a table of the existing NAT46 Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
 3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
 4. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
 7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 8. Set the **Action** parameter. Select one of the following options for the action:
 - **ACCEPT** - lets the traffic through to the next phase of analysis
 - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

Settings if the **ACCEPT** action is selected.

Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv4 to IPv6, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
 - **Use Outgoing Interface Address**
 - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

15. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

Settings if the DENY action is selected

Enable the Log Violation Traffic setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

Central SNAT

The Central NAT feature is not enabled by default. When `central-nat` is enabled, `nat` option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`.

- Info messages and redirection links have been added to IPv4 policy list and dialog to indicate the above
- If NGFW mode is policy-based, then it is assumed that central-nat (specifically SNAT) is enabled implicitly
- The option to toggle NAT in central-snat-map policies has been added (previously it was only shown in NGFW policy-based mode).
- In central-snat policy dialog, the port-mapping fields for the original port have been updated to accept ranges.
- Nat will be skipped in firewall policy if per vdom central nat is enabled.
- The Central SNAT window contains a table of all of the Central SNAT policies.

To toggle the feature on or off, use the following commands:

```
config system settings
    set central-nat [enable | disable]
end
```

When Central NAT is enabled the **Central SNAT** section will appear under the Policy & Objects heading in the GUI.

To configure a Central SNAT entry in the GUI

1. Goto **Policy & Objects > Central SNAT**

The right side window will display a table of the existing Central SNAT entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.
 3. Set the **Outgoing Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to

the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.

4. Set the **Source Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed. For more information on addresses, check the Firewall Objects section called [Addresses](#).
5. Set the **Destination Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.

Under the NAT Heading

6. Set the **IP Pool Configuration** parameter by selecting either **Use Outgoing Interface Address** or **Use Dynamic IP Pool**.
 - If Use Dynamic IP Pool is chosen, a field will appear just beneath the option that is used to select which IP Pool object will be used. Set the IP Pool by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available objects.

7. Set the **Protocol** parameter.

There are 5 options for the **Protocol**.

- **ANY** - any protocol traffic
- **TCP** - TCP traffic only. Protocol number set to 6
- **UDP** - UDP traffic only. Protocol number set to 17
- **SCTP** - SCTP traffic only. Protocol number set to 132
- **Specify** - User can specify the traffic filter protocol by setting the protocol number in the field.

6. If the IP Pool is of the type: Overload, **Explicit Port Mapping** can be enabled.

To enable or disable, use the check box. Once enabled, the following additional parameters will appear.

- **Original Source Port** - in the left number field, set the starting number of the source port range.
- **Translated Port** - in the left number field, set the starting number of the translated port range. If it is a single port range leave the right number field alone. If the right number field is set to a number higher than the left, the right number field for the Original Source Port will change to make sure the 2 number ranges have a matching number of ports.

7. Select the **OK** button to save the entry.

To configure Central SNAT in the CLI

1. Using the CLI interface of your choice, run the following command to get to the correct context.

```
config firewall central-snat-map
```

 - To edit an existing entry, run the command `show` or `show full-configuration` to get a listing of all of the entries in the map. Take note of the policy ID for the entry to be edited.
 - To create a new entry the next step will use the policy ID 0 which will check for an unused ID number and create an entry with that number.

2. Edit or create an entry with the correct policy ID

```
edit <policyID number>
```

Run the following commands to set the parameters of the entry:

```
set status [enable|disable]
```

```
set orig-addr <valid address object preconfigured on the FortiGate>
set srcintf <name of interface on the FortiGate>
set dst-addr <valid address object preconfigured on the FortiGate>
set dstintf <name of interface on the FortiGate>
set protocol <integer for protocol number>
set orig-port <integer for original port number>
set nat-port <integer for translated port number>
```

3. Save the entry by running the command `end` or `next`.

Example scenarios to showing how CLI treats central-nat

Make nat available regardless of NGFW mode.

```
config firewall central-snat-map
edit 1
    set orig-addr "192-86-1-86"
    set srcintf "port23"
    set dst-addr "192-96-1-96"
    set dstintf "port22"
    set nat-ippool "pool1"
    set protocol 17
    set orig-port 2896-2897
    set nat enable
end
```

Hide nat-port if nat-ippool is not set or NAT is disabled.

```
config firewall central-snat-map
edit 1
    set orig-addr "192-86-1-86"
    set srcintf "port23"
    set dst-addr "192-96-1-96"
    set dstintf "port22"
    set nat-ippool "pool1"
    set protocol 17
    set orig-port 2896-2897
    set nat disable
end
```

Change orig-port to accept range

```
config firewall central-snat-map
edit 1
    set orig-addr "192-86-1-86"
    set srcintf "port23"
    set dst-addr "192-96-1-96"
    set dstintf "port22"
    set nat-ippool "pool1"
    set protocol 17
    set orig-port 2896-2897 (help text changed to: Original port or port range).
    set nat-port 35804-35805
end
```

IPv4 Access Control List

The **IPv4 Access Control List** is a specialized policy for denying IPv4 traffic based on:

- the incoming interface
- the source addresses of the traffic
- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**.

This feature is available on FortiGates with NP6 processors and is not supported by FortiGates with NP6lite processors.

To configure a IPv4 Access Control List entry in the GUI

1. Go to **Policy & Objects > IPv4 Access Control List**

The right side window will display a table of the existing IPv4 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Toggle whether or not to **Enable this policy**. The default is enabled.
 7. Select the **OK** button to save the policy.

To configure a IPv4 Access Control List entry in the CLI

Use the following syntax:

```
config firewall acl
  edit <acl Policy ID #>
    set status enable
    set interface <interface>
    set srcaddr <address object>
    set dstaddr <address object>
    set service <service object>
  end
end
```

IPv6 Access Control List

The **IPv6 Access Control List** is a specialized policy for denying IPv6 traffic based on:

- the incoming interface
- the source addresses of the traffic
- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**.

This feature is available on FortiGates with NP6 processors and is not supported by FortiGates with NP6lite processors.

To configure a IPv6 Access Control List entry in the GUI

1. Goto **Policy & Objects > IPv6 Access Control List**

The right side window will display a table of the existing IPv6 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
 - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Toggle whether or not to **Enable this policy**. The default is enabled.
 7. Select the **OK** button to save the policy.

To configure a IPv6 Access Control List entry in the CLI

Use the following syntax:

```
config firewall acl6
  edit <acl Policy ID #>
    set status enable
    set interface <interface>
    set srcaddr <address object>
    set dstaddr <address object>
    set service <service object>
  end
end
```

IPv4 DoS Policy

To configure a IPv4 DoS Policy in the GUI

1. Goto **Policy & Objects > IPv4 DoS Policy**

The right side window will display a table of the existing IPv4 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
 - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
 3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
 4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
 5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
 6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

L3 Anomalies

- ip_src_session
- ip_dst_session

L4 Anomalies

- tcp_syn_flood
- tcp_port_scan
- tcp_src_session
- tcp_dst_session
- udp_flood
- udp_scan
- udp_src_session
- udp_dst_session
- icmp_flood
- icmp_sweep
- icmp_src_session
- sctp_flood
- sctp_scan
- sctp_src_session
- sctp_dst_session

7. Toggle whether or not to **Enable this policy**. The default is enabled.
8. Select the **OK** button to save the policy.

Example

The company wishes to protect against Denial of Service attack. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The SCTP attack filters are disabled
- The tcp_syn_flood attack's threshold is to be changed from the default to 1000

Configuring the DoS Policy in the GUI

1. Go to **Policy & Objects > Policy > DoS**.
2. Create a new policy
3. Fill out the fields with the following information:

Field	Value
Incoming Interface	wan1
Source Address	all
Destination Addresses	all
Service	ALL

L3 Anomalies

Name	Status	Logging	Action	Threshold
ip_src_session	enabled	enabled	Pass	5000
ip_dst_session	enabled	enabled	Pass	5000

L4 Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>

Name	Status	Logging	Action	Threshold
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>
udp_scan	enabled	enabled	Pass	<default value>
udp_src_session	enabled	enabled	Pass	<default value>
udp_dst_session	enabled	enabled	Pass	<default value>
icmp_flood	enabled	enabled	Pass	<default value>
icmp_sweep	enabled	enabled	Pass	<default value>
icmp_src_session	enabled	enabled	Pass	<default value>
icmp_dst_session	enabled	enabled	Pass	<default value>
sctp_flood	not enabled	not enabled	Pass	<default value>
sctp_scan	not enabled	not enabled	Pass	<default value>
sctp_src_session	not enabled	not enabled	Pass	<default value>
sctp_dst_session	not enabled	not enabled	Pass	<default value>

4. Toggle the button next to **Enable this policy** to **ON**.
5. Select **OK**.

Configuring the IPv4 DoS Policy in the GUI

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy
edit 0
    set status enable
    set interface wan1
    set srcaddr all
    set dstaddr all
    set service ALL
    config anomaly
        edit "tcp_syn_flood"
            set status enable
            set log disable
            set action block
            set threshold 1000
        next
        edit "tcp_port_scan"
            set status enable
```

```
        set log disable
        set action block
        set threshold 1000
    next
edit "tcp_src_session"
    set status enable
    set log disable
    set action block
    set threshold 5000
    next
edit "tcp_dst_session"
    set status enable
    set log disable
    set action block
    set threshold 5000
    next
edit "udp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 2000
    next
edit "udp_scan"
    set status enable
    set log disable
    set action pass
    set quarantine none
    set threshold 2000
    next
edit "udp_src_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
    next
edit "udp_dst_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
    next
edit "icmp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 250
    next
edit "icmp_sweep"
    set status enable
    set log disable
    set action pass
    set threshold 100
    next
edit "icmp_src_session"
    set status enable
    set log disable
    set action pass
```

```
        set threshold 300
    next
edit "icmp_dst_session"
    set status enable
    set log disable
    set action pass
    set threshold 1000
next
edit "ip_src_session"
    set status disable
    set log enable
    set action pass
    set threshold 5000
next
edit "ip_dst_session"
    set status disable
    set log enable
    set action pass
    set threshold 5000
next
edit "sctp_flood"
    set status disable
    set log disable
    set action pass
    set threshold 2000
next
edit "sctp_scan"
    set status disable
    set log disable
    set action pass
    set threshold 1000
next
edit "sctp_src_session"
    set status disable
    set log disable
    set action pass
    set threshold 5000
next
edit "sctp_dst_session"
    set status disable
    set log disable
    set action pass
    set threshold 5000
next
end
end
end
```

In this example of the CLI, all of the relevant settings have been left in, but some of them are default settings and would not have to have been specifically set to work. For instance, if the action parameter is not set it automatically defaults to pass.

IPv6 DoS Policy

To configure a IPv6 DoS Policy in the GUI

1. Go to **Policy & Objects > IPv6 DoS Policy**

The right side window will display a table of the existing IPv6 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.

3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).

4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.

5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).

6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

L3 Anomalies

- ip_src_session
- ip_dst_session

L4 Anomalies

- tcp_syn_flood
- tcp_port_scan
- tcp_src_session
- tcp_dst_session
- udp_flood
- udp_scan
- udp_src_session
- udp_dst_session
- icmp_flood
- icmp_sweep
- icmp_src_session

- icmp_dst_session
- sctp_flood
- sctp_scan

7. Toggle whether or not to **Enable this policy**. The default is enabled.
8. Select the **OK** button to save the policy.

Configuring the IPv6 DoS Policy in the GUI

The configuring of the IPv6 version of the DoS policy is the same as in the IPv4 version , with the exception of first command.

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy6
```

The rest of the settings are the same as in IPv4 Dos Policy.

Multicast Policy

The **Multicast Policy** GUI page has been updated from previous versions of the firmware to the new GUI look and feel. Some functionality has also been changed.

The DNAT option has been removed from the GUI but is still in the CLI.

To create/edit a multicast policy go to **Policy & Objects > Multicast Policy**. The Listing window on the right will have buttons along the top that will enable you to

- **Create New**
- **Edit**
- **Delete**

There is also a **Search** field that will allow you to search or filter the available policies if you have a lot of them.

To configure a new policy left click on the **Create New** button. This will reveal the New Policy editing window.

1. Using the drop down menu, fill in the field for **Incoming Interface**. Only one interface can be chosen.
2. Using the drop down menu, fill in the field for **Outgoing Interface**. Only one interface can be chosen.
3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. When the field is selected a window will slide out from the right. In order for a multicast address to be available for selection, the address object needs to have been created already. Only useable address options will be available for selection. This means only multicast address objects and the more generic **all** and **none** options. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
5. Set the **Action** parameter. This will be to either **ACCEPT** or **DENY** the traffic through the policy.
6. Toggle the **Enable SNAT** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
7. Use the drop down menu to select a **Protocol**. The options are:
 - **Any**
 - **ICMP**

- **IGMP**
 - **TCP** - includes **Port Range** fields
 - **UDP** - includes **Port Range** fields
 - **OSPF**
 - **Other** - includes a field for the protocol number
8. Depending on which Protocol is defined, the some other fields may appear.
 - **Port Range** - The first field is for the starting value for the port and the second for the ending value for the port range used by the protocol. Both of these values are inclusive.
 - Protocol field - This appears when the **Other** option is chosen. Enter the value of the protocol number for the protocol you wish to use.
 9. Toggle the **Log Allowed Traffic** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
 10. Toggle the **Enable this policy** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled. By default, this should be enabled
 11. Click on the **OK** button to save the policy.

Object Configuration

As was mentioned earlier, the components of the FortiGate firewall go together like interlocking building blocks. The Firewall objects are a prime example of those building blocks. They are something that can be configured once and then used over and over again to build what you need. They can assist in making the administration of the FortiGate unit easier and more intuitive as well as easier to change. By configuring these objects with their future use in mind as well as building in accurate descriptions the firewall will become almost self documenting. That way, months later when a situation changes, you can take a look at a policy that needs to change and use a different firewall object to adapt to the new situation rather than build everything new from the ground up to accommodate the change.

This chapter includes information about the following Firewall objects:

- [Addresses](#)
- ["Virtual IPs" on page 1085](#)
- [IP Pools](#)
- ["Services" on page 1097](#)
- ["Firewall schedules" on page 1104](#)

UUID Support

A Universally Unique Identified (UUID) attribute has been added to some firewall objects, so that the logs can record these UUID to be used by a FortiManager or FortiAnalyzer unit. The objects currently include:

- Addresses, both IPv4 and IPv6
- Address Groups, both IPv4 and IPv6
- Virtual IPs, both IPv4 and IPv6
- Virtual IP groups, both IPv4 and IPv6
- Policies, IPv4, IPv6 and IP64

A UUID is a 16-octet (128-bit) number that is represented by 32 lowercase hexadecimal digits. The digits are displayed in five groups separated by hyphens (-). The pattern is 8-4-4-4-12; 36 digits if you include the hyphens.

Note: UUID is only supported on large-partition platforms ($\geq 128\text{M}$)

Addresses

Firewall addresses define sources and destinations of network traffic and are used when creating policies. When properly set up these firewall objects can be used with great flexibility to make the configuration of firewall policies simpler and more intuitive. The FortiGate unit compares the IP addresses contained in packet headers with a security policy's source and destination addresses to determine if the security policy matches the traffic.

The address categories and the types within those categories on the FortiGate unit can include:

- IPv4 addresses
 - IP address and Netmask
 - IP address range
 - Geography based address
 - Fully Qualified Domain Name (FQDN) address
 - Wildcard FQDN
 - IPv4 Address Group
- IPv6 addresses
 - Subnets
 - IP range
 - IPv6 Address Group
- Multicast addresses
 - Multicast IP range
 - Broadcast subnets
- Proxy Addresses
 - URL Pattern
 - Host Regex Match
 - URL Category
 - HttpMethod
 - User Agent
 - HTTP Header
 - Advanced (Source)
 - Advanced (Destination)
- IP Pools (IPv4)
 - Overload
 - One-to-one
 - Fixed Port Range
 - Port Block Allocation
- IP Pools (IPv6)
- Virtual IP Addresses
 - IPv4
 - IPv6
 - NAT46
 - NAT64

Interfaces

When setting up an address one of the parameters that is asked for is the interface. This means that the system will expect to see that address only on the interface that you select. You can only select one interface. If you expect that the address may be seen at more than one interface you can choose the “any” interface option. Whenever, possible it is best to choose a more specific interface than the “any” option because in the GUI configuration of firewall policies there is a drop down field that will show the possible addresses that can be used. The drop down will only show those addresses that can be on the interface assigned for that interface in the policy.

Example:

- You have an address called “XYZ”.
- “XYZ” is set to the WAN1 interface because that is the only interface that will be able to access that address.
- When you are selecting a Source Address in the Web-based Manager for a policy that is using the DMZ the address “XYZ” will not be in the drop-down menu.

When there are only 10 or 20 addresses this is not a concern, but if there are a few hundred addresses configured it can make your life easier.

Addresses, address groups, and virtual IPs must have unique names to avoid confusion in firewall policies. If an address is selected in a policy, the address cannot be deleted until it is deselected from the policy.

Addressing Best Practices Tip

The other reason to assign a specific interface to addresses is that it will prevent you from accidentally assigning an address where it will not work properly. Using the example from earlier, if the “XYZ” address was assigned to the “Any” interface instead of WAN1 and you configure the “XYZ” address.

Addressing Best Practices Tip

Don't specify an interface for VIP objects or other address objects that may need to be moved or approached from a different direction. When configuring a VIP you may think that it will only be associated with a single interface, but you may later find that you need to reference it on another interface.

Example: Some web applications require the use of a FQDN rather than an IP address. If you have a VIP set up that works from the Internet to the Internal LAN you won't be able to use that VIP object to access it from an internal LAN interface.

IPv4 Addresses

When creating an IPv4 address there are a number of different types of addresses that can be specified. These include:

- FQDN
- Geography

- IP Range
- IP/Netmask
- Wildcard FQDN

Which one chosen will depend on which method most easily yet accurately describes the addresses that you are trying to include with as few entries as possible based on the information that you have. For instance, if you are trying to describe the addresses of a specific company's web server but if you have no idea of how extensive there web server farm is you would be more likely to use a Fully Qualified Domain Name (FQDN) rather than a specific IP address. On the other hand some computers don't have FQDNs and a specific IP address must be used.

The following is a more comprehensive description of the different types of addresses.

FQDN Addresses

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of DNS to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host_name>.<top_level_domain_name> such as example.com
- <host_name>.<second_level_domain_name>.<top_level_domain_name>, such as mail.example.com

When creating FQDN entries it is important to remember that:

- Wildcards are not supported in FQDN address objects
- While there is a level of convention that would imply it, "www.example.com" is not necessarily the same address of "example.com". they will each have their own records on the DNS server.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. DNS servers in the past were not seen as potential targets because the thinking was that there was little of value on them and therefore are often not as well protected as some other network resources. People are becoming more aware that the value of the DNS server is that in many ways it controls where users and computers go on the Internet. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.

3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **FQDN** from the drop down menu.
6. Input the domain name in the **FQDN** field.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: FQDN address

You have to great a policy that will govern traffic that goes to a site that has a number of servers on the Internet. Depending on the traffic or the possibility that one of the servers is down network traffic can go to any one of those sites. The consistent factor is that they all use the same Fully Qualified Domain Name.

- The FQDN of the web site: example.com
- The number of ISP connections off of the FortiGate firewall: 2

Configuring the address in the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information:

Category	Address
Name	BigWebsite.com
Type	FQDN
FQDN	bigwebsite.com
Interface	any
Show in Address List	<enable>
Comments	<Input into this field is optional>

3. Select **OK**.

Configuring the address in the CLI

```
config firewall address
  edit BigWebsite.com
    set type fqdn
    set associated-interface any
    set fqdn bigwebsite.com
  end
```

Verification

To verify that the addresses were added correctly:

1. Go to **Firewall Objects > Address > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address
edit <the name of the address that you wish to verify>
Show full-configuration
```

Changing the TTL of a FQDN address

To make sure that the FQDN resolves to the most recent active server you have been asked to make sure that the FortiGate has not cached the address for any longer than 10 minutes.

There is no field for the cached time-to-live in the web-based manager. It is only configurable in the CLI. Enter the following commands:

```
config firewall address
edit BigWebsite.com
set cache-ttl 600
end
```

Geography Based Addresses

Geography addresses are those determined by country of origin.

This type of address is only available in the IPv4 address category.

Creating a Geography address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Geography** from the drop down menu.
6. In the **Country** field, select a single country from the drop down menu.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: Geography-based Address

Configuring the address in the GUI

Your company is US based and has information on its web site that may be considered information that is not allowed to be sent to embargoed countries. In an effort to help reduce the possibility of sensitive information going to those countries you have be asked to set up addresses for those countries so that they can be block in the firewall policies.

- One of the countries you have been asked to block is Cuba
- You have been asked to comment the addresses so that other administrators will know why they have been created

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information

Category	Address
Name	Cuba
Type	Geography
Country	Cuba
Interface	any
Visibility	<enable>
Comments	Embargoed

3. Select **OK**.

Configuring the address in the CLI

Enter the following CLI commands:

```
config firewall address
edit Cuba
    set type geography
    set country CN
    set interface wan1
end
```

Overrides

It is possible to assign a specific ip address range to a customized country ID. Generally, geographic addressing is done at the VDOM level; it could be considered global if you are using the root VDOM, but the geoip-override setting is a global setting.

```
config system geoip-override
edit "test"
    set country-id "A0"
    config ip-range
        edit 1
            set start-ip 7.7.7.7
            set end-ip 7.7.7.8
        next
        edit 2
            set start-ip 7.7.10.1
            set end-ip 7.7.10.255
        end
    end
```

- While the setting exists in the configuration file, the system assigns the country-id option automatically.
- While you can use "edit 1" and "edit 2", it is simpler to use "edit 0" and let the system automatically assign an ID number.

After creating a customized Country by using geoip-override command, the New country name has been added automatically to the country list and will be available on the Firewall Address Country field.

Diagnose commands

There are a few diagnose commands used with geographic addresses. The basic syntax is:

```
diagnose firewall ipgeo [country-list | ip-list | ip2country | override |
copyright-notice]
```

Diagnose command	Description
country-list	Listing of all the countries.
ip-list	List of the IP addresses associated with the country
ip2country	Used to determine which country a specific IP address is assigned to.
override	Listing of user defined geography data - items configured by using "config system geoip-override" command.
copyright-notice	Shows the copyright notice.

Click on the diagnose command in the table to connect to the Fortinet Diagnose Wiki page that deals with the command option, to get more information.

IP Range Addresses

Where the Subnet address is good at representing a standardized group of addresses that are subnets the IP Range type of address can describe a group of addresses while being specific and granular. It does this by specifying a continuous set of IP addresses between one specific IP address and another. While it is most common that this range is with a subnet it is not a requirement. For instance, 192.168.1.0/24 and 192.168.2.0/24 would be 2 separate subnets but if you wanted to describe the top half of one and the bottom half of the other you could describe the range of 192.168.1.128-192.168.2.127. It's also a lot easier than trying to calculate the correct subnet mask.

The format would be:

x.x.x.x-x.x.x.x, such as 192.168.110.100-192.168.110.120

There is a notation that is commonly used and accepted by some devices that follows the format:

x.x.x.[x-x], such as 192.168.110.[100-120]

This format is not recognized in FortiOS 5.2 as a valid IP Range.

Creating a IP Range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **Address**(IPv4 addresses) or **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP Range** from the drop down menu.
6. In the **Subnet / IP Range** field, enter the range of addresses in the following format: x.x.x.x-x.x.x.x (no spaces)
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu. (This setting is not available for IPv6 addresses)
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
Category	Address or IPv6 Address
Name	Guest_users
Type	IP Range
Subnet / IP Range	192.168.100.200-192.168.100.240
Interface	Port1
Show in Address List	[on]
Comments	Computers on the 1st floor used by guests for Internet access.

IP Range addresses can be configured for both IPv4 and IPv6 addresses. The only differences in creating an IPv6 IP Range address is that you would choose IPv6 Address for the Category and the syntax of the address in the Subnet/IP Range field would be in the format of 2001:0db8:0000:0002:0:0:0:20-2001:0db8:0000:0004:0:0:0:20

IP / Netmask Addresses

The subnet type of address is expressed using a host address and a subnet mask. From a strictly mathematical stand point this is the most flexible of the types because the address can refer to as little one individual address or as many as all of the available addresses.

It is usually used when referring to your own internal addresses because you know what they are and they are usually administered in groups that are nicely differentiated along the lines of the old A, B, and C classes of IPv4 addresses. They are also addresses that are not likely to change with the changing of Internet Service Providers (ISP).

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a firewall address can be:

- A single host such as a single computer with the address 192.45.46.45
- A range of hosts such as all of the hosts on the subnet 192.45.46.1 to 192.45.46.255
- All hosts, represented by 0.0.0.0 which matches any IP address

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR formatted netmasks to dotted decimal format. Example formats:

- Netmask for a class A subnet of 16,777,214 usable addresses: 255.0.0.0, or /8
- Netmask for a class B subnet of 65,534 usable addresses: 255.255.0.0, or /16
- Netmask for a class C subnet of 254 usable addresses: 255.255.255.0, or /24
- Netmask for subnetted class C of 126 usable addresses: 255.255.255.128, or /25
- Netmask for subnetted class C of 62 usable addresses: 255.255.255.128, or /26
- Netmask for subnetted class C of 30 usable addresses: 255.255.255.128, or /27
- Netmask for subnetted class C of 14 usable addresses: 255.255.255.128, or /28
- Netmask for subnetted class C of 6 usable addresses: 255.255.255.128, or /29
- Netmask for subnetted class C of 2 usable addresses: 255.255.255.128, or /30
- Netmask for a single computer: 255.255.255.255, or /32
- Netmask used with 0.0.0.0 to include all IP addresses: 0.0.0.0, or /0

So for a single host or subnet the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

Static Route Configuration

A setting that is found in the IP/Netmask address type that is not found in the other address types is the enabling or disabling of **Static Route Configuration**. Enabling this feature includes the address in the listing of named addresses when setting up a static route.

To use in the GUI

1. Enable the **Static Route Configuration** in the address.
2. Go to **Network > Static Routes** and create a new route.
3. For a **Destination** type, choose **Named Address**.

4. Using the drop down menu, enter the name of the address object in the field just underneath the **Destination** type options.
5. Fill out the other information relevant to the route
6. Select the **OK** button

To enable in the CLI:

```
config firewall address
  edit <address_name>
    set allow-routing enable
  end
```

Creating a Subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP/Netmask** from the drop down menu.
6. In the **Subnet/IP Range** field, enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Select the desired on/off toggle setting for **Static Route Configuration**.
10. Input any additional information in the **Comments** field.
11. Press **OK**.

Example

Example of a Subnet address for a database server on the DMZ:

Field	Value
Category	Address
Name	DB_server_1
Type	IP/Netmask
Subnet/IP Range	United States
Interface	any
Show in Address List	[on]
Static Route Configuration	[off]
Comments	

Wildcard FQDN

There are a number of companies that use secondary and even tertiary domain names or FQDNs for their websites. Wildcard FQDN addresses are to ease the administrative overhead in cases where this occurs. Sometimes its as simple as sites that still use www. as a prefix for their domain name. If you don't know whether or not the www is being used it's simpler to use a wildcard and include all of the possibilities whether it be example.com, www.example.com or even ftp.example.com.

The following wildcard character instances are supported in wildcard FQDN addresses:

- "?" character
- "*" character in the middle of a phrase
- The "?*" combination

Wildcard FQDN addresses do not resolve to a specific set of IP addresses in the same way that a normal FQDN address does. They are intended for use in SSL exemptions and should not be used as source or destination addresses in policies.

Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Wildcard FQDN** from the drop down menu.
6. Input the domain name in the **Wildcard FQDN** field.
7. In the **Interface** field, leave as the default any or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Example of a FQDN address for a remote FTP server used by Accounting team:

Field	Value
Category	Address
Name	Example.com_servers
Type	Wildcard FQDN
Wildcard FQDN	*.example.com
Interface	any

Field	Value
Show in Address List	[on]
Comments	Secondary and tertiary domain names for example.com

IPv6 Addresses

When creating an IPv6 address there are a number of different types of addresses that can be specified. These include:

- Subnet
- IP Range - the details of this type of address are the same as the IPv4 version of this type

The IPv6 addresses don't yet have the versatility of the IPv4 address in that they don't have things like geography based or FQDN address but as IPv6 becomes more mainstream this should change.

Subnet Addresses

The Subnet Address type is one that is only used in reference to IPv6 addresses. It represents an IPv6 address subnet. This means that the address will likely be a series of hexadecimal characters followed by a double colon, followed by a "/", and then a number less than 128 to indicate the size of the subnet. An example would be:

fd5e:3c59:35ce:f67e::/64

- The hexadecimal characters represent the IPv6 subnet address.
- The "::" indicates 0's from that point to the left. In an actual address for a computer, the hexadecimal characters that would take the place of these zeros would represent the device address on the subnet.
- /xx, in this case /64 represents the number of bits in the subnet. This will make a range that can potentially include 18,446,744,073,709,551,616 addresses. For those wanting to use English rather than math, that is 18 Quintillion.

Creating a Subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Subnet** from the drop down menu.
6. In the **Subnet / IP Range** field, enter the range of addresses in IPv6 format (no spaces)
7. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
8. Input any additional information in the **Comments** field.
9. Press **OK**.

Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
Category	IPv6 Address
Name	IPv6_Guest_user_range
Type	Subnet
Subnet / IP Range	fd5e:3c59:35ce:f67e::/64
Show in Address List	[on]
Comments	

Multicast Addresses

Multicast addressing defines a specific range of address values set aside for them. Therefore all IPv4 multicast addresses should be between 224.0.0.0 and 239.255.255.255.

More information on the concepts behind Multicast addressing can be found in the Multicast Forwarding section.

Multicast IP Range

This type of address will allow multicast broadcasts to a specified range of addresses.

Creating a Multicast IP Range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**.
 - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, Multicast Address**
4. Input a **Name** for the address object.
5. Select the **Type, Multicast IP Range** from the dropdown menu.
6. Enter the value for the **Multicast IP Range**
7. Select the **Interface** from the dropdown menu.
8. Enable the **Show in Address List** function
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example: Multicast IP Range Address

The company has a large high tech campus that has monitors in many of its meeting rooms. It is common practice for company wide notifications of importance to be done in a streaming video format with the CEO of the company addressing everyone at once.

The video is High Definition quality so takes up a lot of bandwidth. To minimize the impact on the network the network administrators have set things up to allow the use of multicasting to the monitors for these notifications. Now it has to be set up on the FortiGate firewall to allow the traffic.

- The range being used for the multicast is 239.5.5.10 to 239.5.5.200
 - The interface on this FortiGate firewall will be on port 9
1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
 2. Fill out the fields with the following information

Category	Multicast Address
Name	Meeting_Room_Displays
Type	Multicast IP Range
Multicast IP Range	239.5.5.10-239.5.5.200
Interface	port9
Show in Address List	<enable>
Comments	<Input into this field is optional>

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall multicast-address
edit "meeting_room_display"
set type multicastrange
set associated-interface "port9"
set start-ip 239.5.5.10
set end-ip 239.5.5.200
set visibility enable
next
end
```

To verify that the address range was added correctly:

1. Go to **Policy & Objects > Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall multicast-address
edit <the name of the address that you wish to verify>
Show full-configuration
```

Broadcast Subnet

This type of address will allow multicast broadcast to every node on a subnet.

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Multicast Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Broadcast Subnet** from the drop down menu.

6. In the **Broadcast Subnet** field enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x. (Remember, it needs to be within the appropriate IP range 224.0.0.0 to 239.255.255.255)
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

Example

Field	Value
Category	Broadcast Subnet
Name	Corpnet-B
Type	Broadcast Subnet
Broadcast Subnet	224.5.5.0/24
Interface	any
Show in Address List	[on]
Comments	Corporate Network devices - Broadcast Group B

Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. The following table lists the reserved multicast address ranges and describes what they are reserved for:

Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).

Reserved Address Range	Use	Notes
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to **Firewall Objects > Address > Addresses** and selecting **Create New > Multicast Address**. The factory default configuration includes multicast addresses for Bonjour (224.0.0.251-224.0.0.251), EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all_hosts (224.0.0.1-224.0.0.1), and all_routers (224.0.0.2-224.0.0.2).

Proxy Addresses

This category of address is different from the other addresses in that it is not designed to be used in the normal firewall policy configuration. It is intended to be used only with explicit web proxies.

In some respects they can be like a FQDN addresses in that they refer to an alpha-numeric string that is assigned to an IP address, but then goes an additional level of granularity by using additional information and criteria to further specify locations or types of traffic within the website itself.

Creating an Proxy address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Proxy Address**.
4. Input a **Name** for the address object.
5. For the **Type** field, select one of the options from the drop down menu.

Within the Explicit Proxy Address category there are 8 types of addresses. Each of these types will have associated field(s) that also need to have values entered to make the object specific to it's address.

Type = URL Pattern

- In the **Host** field, choose from drop down menu
- In the **URL Path Regex** field, enter the appropriate string

Host Regex Match

- In the **Host Regex Pattern** field, enter the appropriate string

URL Category

- In the **Host** field, choose from drop down menu
- In the **URL Category** field, choose from drop down menu

HTTP Method

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu

The options are:

- CONNECT
- DELETE
- GET
- HEAD
- OPTIONS
- POST
- PUT
- TRACE

User Agent

- In the **Host** field, choose from drop down menu
- In the **User Agent** field, choose from drop down menu

The options are:

- Apple Safari
- Google Chrome
- Microsoft Internet Explorer or Spartan
- Mozilla Firefox
- Other browsers

HTTP Header

- In the **Host** field, choose from drop down menu
- In the **Header Name** field, enter the appropriate string value
- In the **Header Regex** field, enter the appropriate string value

Advanced (Source)

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu (see **HTTP Method** type for option list)
- In the **User Agent** field, choose from drop down menu (see **User Agent** type for option list)
- In the **Header Group** table, create, edit or delete **Header Name** strings and associated **Header Regex** strings

Advance (Destination)

- In the **Host** field, choose from drop down menu
- In the **Host Regex Pattern** field, enter the appropriate string
- In the **URL Category** field, choose from drop down menu

6. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
7. Input any additional information in the **Comments** field.
8. Press **OK**.

Proxy Address Groups

To create a Proxy address group:

1. Go to **Policy & Objects > Addresses**.
2. Click on **+ Create New** to get the drop down menu. Select **Address Group**.
3. In the **Category** field, choose **Proxy Group**.
4. Fill in a descriptive name in the **Group Name** field.
5. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
6. In the Type field, select whether the group will be a **Source Group** (composed of source addresses) or a **Destination Group** (composed of destination addresses).
7. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Click on **OK**.

Internet Services

In FortiOS 5.4, support was added for Internet Service objects which could be used with **FortiView**, **Logging**, **Routing** and **WAN Load Balancing**. Now they can be added to firewall policies as well.

There is an either or relationship between Internet Service objects and destination address and service combinations in firewall policies. This means that a destination address and service can be specified in the policy OR an Internet service, not both.

CLI

The related CLI options/syntax are:

```

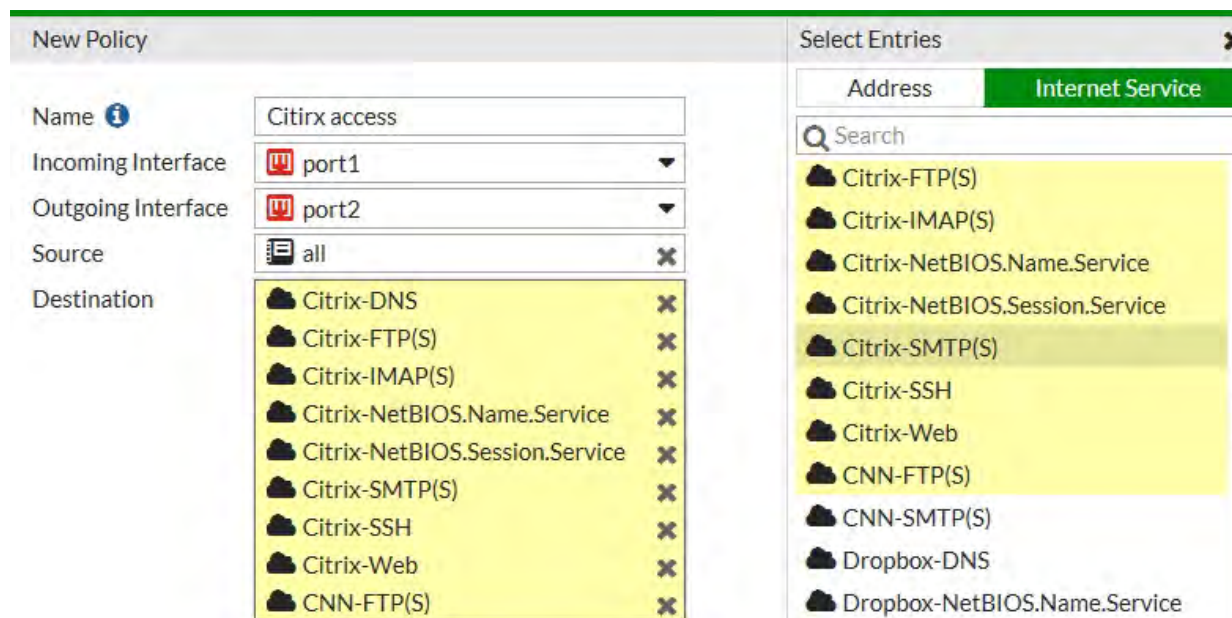

config firewall policy
  edit 1
    set internet-service 1 5 10
    set internet-service-custom test
    set internet-service-negate [enable|disable]
  end

```

GUI

In the policy listing page you will notice that is an Internet Service object is used, it will be found in both the **Destination** and **Service** column.

In the policy editing page the **Destination Address**, now **Destination** field now has two types, **Address** and **Internet Service**.

Address Groups

Address groups are designed for ease of use in the administration of the device. If you have a number of addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy refers to them.

The use of groups is not required. If you have a number of different addresses you could add them individually to a policy and the FortiGate firewall will process them just as quickly and efficiently as if they were in a group, but the chances are that if you have used a group once you could need to use it again and depending on the number of addresses involved entering them individually for each policy can become tedious and the likelihood of an address being missed becomes greater. If you have a number of policies using that combination of addresses it is much easier to add or subtract addresses from the group than to try and remember all of the firewall policies that combination of addresses was used in. With the group, you only have to make the one edit and it is used by any firewall policy using that address group.

Because security policies require addresses with homogenous network interfaces, address groups should contain only addresses bound to the same network interface, or to Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

There are 3 Categories of Address groups to choose from:

- IPv4 Group
- IPv6 Group
- Proxy Group

You cannot mix different categories of addresses within a group, so whether or not it makes sense from an administrative purpose to group certain addresses together, if some are IPv4 and some are IPv6, it cannot be done.

Creating an Address Group

1. Go to **Policy & Objects > Addresses**.
2. Select the down arrow next to **Create New**, select **Address Group**.
3. Choose the **Category**, that is applicable to the proposed selection of addresses.
4. Input a **Group Name** for the address object.

Depending on which **Category** has been chosen the configurations will differ slightly

IPv4 Group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.
3. Select the desired on/off toggle setting for **Static Route Configuration**.

IPv6 Group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.

Proxy Group

1. Select which Type, either **Source Group** or **Destination Group**.
2. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
3. Select the desired on/off toggle setting for **Show in Address List**.

Irrespective of the Category the groups all have the same final configuration options:

1. Input any additional information in the **Comments** field.
2. Press **OK**.

UUID Support

Syntax:

```
config firewall {address|address6|addgrp|addgrp6}
edit 1
    set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
next
end
```

Virtual IPs

The mapping of a specific IP address to another specific IP address is usually referred to as Destination NAT. When the Central NAT Table is not being used, FortiOS calls this a Virtual IP Address, sometimes referred to as a VIP. FortiOS uses a DNAT or Virtual IP address to map an External IP address to an IP address. This address does not have to be an individual host, it can also be an address range. This mapping can include all TCP/UDP ports or if Port Forwarding is enabled it will only refer to the specific ports configured. Because, the Central NAT table is disabled by default the term Virtual IP address or VIP will be used predominantly.

Virtual IP addresses are typically used to NAT external or Public IP addresses to internal or Private IP addresses. Using a Virtual IP address between 2 internal Interfaces made up of Private IP addresses is possible but there is rarely a reason to do so as the 2 networks can just use the IP addresses of the networks without the need for any address translation. Using a Virtual IP address for traffic going from the inside to the Internet is even less likely to be a requirement, but it is supported.

Something that needs to be considered when there are multiple Public IP addresses on the external interface(s) is that when a Virtual IP address is used without Port Forwarding enabled there is a reciprocal effect as far as traffic flow is concerned. Normally, on a firewall policy where NAT is enabled, for outgoing traffic the internal address is translated to the Public address that is assigned to the FortiGate, but if there is a Virtual IP address with no port forwarding enabled, then the Internal IP address in the Mapped field would be translated to the IP address configured as the External Address in the VIP settings.

Example

- The assigned External address (WAN1) of the FortiGate unit is 172.12.96.3 with a subnet mask of 255.255.255.128
- There is a Virtual IP address set up to map the external address 172.12.96.127 on WAN1 to the internal IP address of 192.168.1.127
- Port Forwarding is not enabled because you want all allowed traffic going to the external IP address to go to this server.

In this case any outbound traffic from 192.168.1.127 will go out on WAN1 with the IP address of 172.12.96.127 as the source IP address.

In terms of actually using the Virtual IP address, they would be using in the security policies in the same places that other addresses would be used, usually as a Destination Address.

UUID Support for VIP

UUID is now supported in for virtual IPs and virtual IP groups. This includes virtual IPs for IPv4, IPv6, NAT46, and NAT64. To view the UUID for these objects in a FortiGate unit's logs, log-uuid must be set to extended mode, rather than policy-only (which only shows the policy UUID in a traffic log). UUID can only be configured through the CLI

Syntax

```
config sys global
    set log-uuid {disable | policy-only | extended}
end
```

There is another type of address that the term “virtual IP address” commonly refers to which is used in load balancing and other similar configurations. In those cases, a number of devices share a separately created virtual IP address that can be sent to multiple possible devices. In FortiOS these are referred to as Virtual Servers and are configured in the “Load Balance” section.

If Central-NAT is enabled in the CLI the GUI will be different.

Instead of **VIP Type**, the field label will be **DNAT & VIP Type**

Instead of **IPv4** the option will be **IPv4 DNAT**

There will also be the addition setting of **Source Interface Filter**.

Commands to set central-nat:

```
config system settings
    set central-nat [enable | disable]
end
```

Creating a Virtual IP

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP**.
3. From the **VIP Type** options, choose an applicable type based on the IP addressing involved. Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface.

The available options are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
 - **IPv6** - IPv6 on both sides of the FortiGate Unit.
 - **NAT46** - Going from an IPv4 Network to an IPv6 Network.
 - **NAT64** - Going from an IPv6 Network to an IPv4 Network.
4. In the **Name** field, input a unique identifier for the Virtual IP.
 5. Input any additional information in the **Comments** field.
 6. The **Color** of the icons that represent the object in the GUI can be changed by clicking on the **[Change]** link and choosing from the 32 colors.

Because the configuration differs slightly for each type the next steps will be under a separate heading based on the type of the VIP

Configuring a VIP for IPv4

In the **Network** section:

7. If an IPv4 type of Virtual IP, select the **Interface** setting.

Using the drop down menu for the Interface Field, choose the incoming interface for the traffic.

The IPv4 VIP Type is the only one that uses this field. This is a legacy function from previous versions so that they can be upgraded without complicated reconfiguration. The External IP address, which is a required field, tells the unit which interface to use so it is perfectly acceptable to choose **"any"** as the interface. In some configurations, if the Interface field is not set to **"any"** the Virtual IP object will not one of the displayed options when choosing a destination address.

8. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. The format of the address will depend on the **VIP Type** option that was selected.

9. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. The format of the address will depend on the **VIP Type** option that was selected.

In the **Optional Filters**

10. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

11. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.

- **Source IP** - Use the standard format for a single IP address
- **Range** - Enter the first and last members of the range
- **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. To specify an allowed Service, toggle the **Services** option to enabled. Set the **Services** parameter by selecting the field with the "+" in the field. This will slide a window out from the right. Single or multiple options can be selected by highlighting the services wanted, unless the **ALL** option is chosen, in which case it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).

13. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.

14. Select the **Protocol** from

- **TCP**
- **UDP**
- **SCTP**
- **ICMP**

15. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

16. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto

populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

17. Press **OK**.

Example

This example is for a VIP that is being used to direct traffic from the external IP address to a web server on the internal network. The web server is for company use only. The company's public facing web server already used port 80 and there is only one IP external IP address so the traffic for this server is being listened for on port 8080 of the external interface and being sent to port 80 on the internal host.

Field	Value
VIP Type	IPv4
Name	Internal_Webserver
Comments	Web server with Collaboration tools for Corporate employees
Interface	Any
External IP Address/Range	172.13.100.27 <this would normally be a public IP address>
Mapped IP Address/Range	192.168.34.150
Optional Filters	enabled
Source Address Filter	<list of IP addresses of remote users>
Services	enabled with HTTP in the list
Port Forwarding	enabled
Map to Port	80 - 80

Configuring a VIP for IPv6

In the **Network** section:

7. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.

8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.

- **Source IP** - Use the standard format for a single IP address
- **Range** - Enter the first and last members of the range
- **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.

13. Select the **Protocol** from

- **TCP**
- **UDP**
- **SCTP**

14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

16. Press **OK**.

Configuring a VIP for NAT46

In the **Network** section:

7. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv4 format.

8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.

- **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.
To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.
12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
 13. Select the **Protocol** from
 - **TCP**
 - **UDP**
 14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
 15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
 16. Press **OK**.

Configuring a VIP for NAT64

In the **Network** section:

7. Configure the **External IP Address/Range**.
There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.
8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.
There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv4 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.
If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
 - **Source IP** - Use the standard format for a single IP address
 - **Range** - Enter the first and last members of the range
 - **Subnet** - Enter the IP address of the broadcast address for the subnet.
To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from
 - TCP
 - UDP
14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

FQDN in VIPs

Instead of mapping to an IP address a VIP can use a FQDN(Fully Qualified Domain Name). This has to be configured in the CLI and the FQDN must be an address object that is already configured in the address listing.

The syntax for using a FQDN is:

```
config firewall vip
  edit <VIP id>
    set type fqdn
    set mapped-addr <FQDN address object>
  end
```

Dynamic VIP according to DNS translation

When a dynamic virtual IP is used in a policy, the dynamic DNS translation table is installed along with the dynamic NAT translation table into the kernel. All matched DNS responses will be translated and recorded regardless if they hit the policy. When a client request hits the policy, dynamic NAT translation will occur if it matches a record, otherwise the traffic will be blocked.

Syntax

```
config firewall vip
  edit "1"
    set type dns-translation
    set extip 192.168.0.1-192.168.0.100
    set extintf "dmz"
    set dns-mapping-ttl 604800
    set mappedip "3.3.3.0/24" "4.0.0.0/24"
  end
end
```

Virtual IP Groups

Just like other address, Virtual IP addresses can be organized into groups for ease of administration. If you have multiple virtual IPs that are likely to be associated to common firewall policies rather than add them individually to

each of the policies you can add the instead. That way, if the members of the group change then any changes made to the group will propagate to all of the policies using that group.

When using a Virtual IP address group the firewall policy will take into account all of the configured parameters of the Virtual IPs: IP addresses, Ports and port types.

Creating a Virtual IP Group

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP Group**.
3. Select the **Type** fo VIP group you wish to create.

The options available are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
- **IPv6** - IPv6 on both sides of the FortiGate Unit.
- **NAT46** - Going from an IPv4 Network to an IPv6 Network.
- **NAT64** - Going from an IPv6 Network to an IPv4 Network.

Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface. The options will be:

4. Enter a unique identifier for the group in the **Name** field.
5. Enter any additional information in the **Comments** field.
6. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
7. If the **Type** is **IPv4**, the **Interface** field will be available. Use the drop-down menu to select the interface if all of the VIPs are on the same interface. If any of the VIPs are on different interfaces or if any of them are associated with the "any" option, choose the any option for the group.
8. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
9. Press **OK**.

Configuring IP pools

An IP pool is essentially one in which the IP address that is assigned to the sending computer is not known until the session is created, therefore at the very least it will have to be a pool of at least 2 potential addresses. A quick example would be an IP pool for users of a VPN. IP pools are based upon the version of IP determined by the interface that they are associated with so as expected there are two types of IP pools that can be configured:

- ["Creating a IPv4 Pool" on page 1092](#)
- ["Creating a IPv6 Pool" on page 1096](#)

Because of the differences in the configuration for the two types of pools, instructions for configuring them will be done separately.

Creating a IPv4 Pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the **IP Pool Type** field choose **IPv4 Pool**
4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. In the **Type** field choose between:

- **Overload**
- **One-to-One**
- **Fixed Port Range**
- **Port Block Allocation**

At this point the configurations can start to differ based on the type of type of pool.

For more information on the different types of IP pools, check [IP Pools](#) in the Concepts section.

Overload

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Enable the **ARP Reply** field by making sure there is a check in the box
9. Select **OK**

Overload Example for GUI

In this example, the Sales team needs to connect to an Application Service Provider that does the accounting for the company. As a security measure, the ASP only accepts traffic from a white list of IP addresses. There is 1 public IP address of the company on that list. The Sales team consists of 40 people, so they need to share. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Sales_Team
Comments	For the Sales team to use to connect to the Accounting ASP
Type	Overload (This is the default)
External IP Range	10.23.56.20 - 10.23.56.20
ARP Reply	enabled

Overload Example for CLI

```
config firewall ippool
edit Sales_Team
    set comments "For the Sales team to use to connect to the Accounting ASP"
    set type overload
    set startip 10.23.56.20
    set endip 10.23.56.20
    set arp-reply enable
    set arp-intf wan1
end
```

One-to-one

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.

8. Enable the **ARP Reply** field by making sure there is a check in the box.
9. Select **OK**

One-to-one Example for GUI

In this example, the external IP address of the mail server is part of a range assigned to the company but not the one that is assigned to the Internet facing interface. A VIP has been set up but in order to properly resolve Reverse DNS lookups the mail server always has to use a specific IP address. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Mail-Server
Comments	So the the correct IP address is resolved on Reverse DNS look ups of the mail server.
Type	One-to-one
External IP Range	10.23.56.21 - 10.23.56.21
ARP Reply	enabled

One-to-one Example for CLI

```
config firewall ippool
  edit Mail-Server
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
      the mail server."
    set type one-to-one
    set startip 10.23.56.21
    set endip 10.23.56.21
    set arp-reply enable
    set arp-intf wan1
  end
```

Fixed Port Range

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. For the **Internal IP Range** fields, enter the lowest and highest addresses in the range.
9. Enable the **ARP Reply** field by making sure there is a check in the box
10. Select **OK**

Fixed Port Range Example for GUI

In this example, the company has a range of 10 IP address that they want to be used by employees on a specific subnet for NATing. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	IPPool-3
Comments	IP range to be used by outgoing traffic
Type	Fixed Port Range
External IP Range	10.23.56.22 - 10.23.56.31
Internal IP Range	192.168.23.1 - 192.168.23.254
ARP Reply	enabled

Fixed Port Range Example for CLI

```
config firewall ippool
edit IPPool-3
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
        the mail server."
    set type fixed-port-range
    set startip 10.23.56.22
    set endip 10.23.56.31
    set source-startip 192.168.23.1
    set source-endip 192.168.23.254
    set arp-reply enable
    set arp-intf wan1
end
```

Port Block Allocation

- For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
- In the **Block Size** field, either type in the value or use the up or down arrows to set the value of the block size.
- In the **Blocks Per User** field, either type in the value or use the up or down arrows to set the value for the number of blocks per user.
- Enable the **ARP Reply** field by making sure there is a check in the box
- Select **OK**

Port Block Allocation Example for GUI

In this example, a small ISP is setting up NATing for its clients, but to be fair it is putting some restrictions on the number of connections each client can have so that no one hogs all of the possible ports and addresses. The external interface is port12.

Field	Value
IP Pool Type	IPv4 Pool

Field	Value
Name	Client-IPPool
Comments	IP Pool for clients to access the Internet
Type	Port Block Allocation
External IP Range	10.23.75.5 - 10.23.75.200
Block Size	64
Blocks Per User	8
ARP Reply	enabled

Port Block Allocation Example for CLI

```
config firewall ippool
edit Client-IPPool
set comments "IP Pool for clients to access the Internet"
set type port-block-allocation
set startip 10.23.75.5
set endip 10.23.75.200
set block-size 64
set num-blocks-per-user 8
set permit-any-host disable
set arp-intf wan1
set arp-reply enable
arp-intf port12
end
```

Creating a IPv6 Pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the IP Pool Type field choose **IPv6 Pool**
4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. For the **External IP Range** fields, enter the lowest and highest addresses in the range.

IPv6 Example for GUI

In this example, there is a similar situation to the One-to-one example earlier. There is a mail server that needs to be resolved to a specific IP address in Reverse DNS look-ups. The difference in this case is the company is an early adopter of IPv6 connectivity to the Internet.

Field	Value
IP Pool Type	IPv6 Pool

Field	Value
Name	Mail-svr-ipv6
Comments	Registered IPv6 address for mail server
External IP Range	fd2f:50ec:cdea:0663::1025 - fd2f:50ec:cdea:0663::1025

Port Block Allocation Example for CLI

```
config firewall ippool6
edit Mail-svr-ipv6
set comments "Registered IPv6 address for mail server"
set startip fd2f:50ec:cdea:663::102
set endip fd2f:50ec:cdea:663::1025
end
```

Services

While there are a number of services already configured within FortiOS, the firmware allows for administrators to configure their own. The reasons for doing this usually fall into one or more of the following categories:

- The service is not common enough to have a standard configuration
- The service is not established enough to have a standard configuration
- The service has a standard port number but there is a reason to use a different one:
 - Port is already in use by another service
 - For security reasons, want to avoid standard port

When looking at the list of preconfigured services it may seem like there are a lot, but keep in mind that the theoretical limit for port numbers is 65,535. This gives a fairly good sized range when you are choosing what port to assign a service but there are a few points to keep in mind.

- Most of the well known ports are in the range 0 - 1023
- Most ports assigned by the Internet Corporation for Assigned Names and Numbers (ICANN) will be in the 1024 - 49151 range
- Port numbers between 49,152 and 65,535 are often used for dynamic, private or ephemeral ports.

There are 3 Service objects that can be added and configured:

- Categories
- Services
- Service Groups

Categories

In order to make sorting through the services easier, there is a field to categorize the services. Because selecting a category is part of the process for creating a new service, the configuration of categories will be explained first.

The services can be sorted into the following groups:

- General
- Web Access

- File Access
- Email
- Network Services
- Authentication
- Remote Access
- Tunneling
- VoIP, Messaging and Other Applications
- Web Proxy
- Uncategorized

The categories are for organization purposes so there is not many settings when creating a new one.

Creating a new Service Category

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Category**
3. Input a **Name** for the category.
4. Input any additional information in the **Comments** field.
5. Press **OK**.

Example

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of "Surveillance"

Example of a New Category in the GUI

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Category**.
2. Fill out the fields with the following information

Field	Value
Name	Surveillance
Comments	For DataCenter Surveillance Devices

3. Select **OK**.

Example of a New Category in the CLI

Enter the following CLI command:

```
config firewall service category
edit Surveillance
set comment "For DataCenter Surveillance Devices"
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services**. Select the Category Settings icon . A listing of the categories should be displayed.
2. Enter the following CLI command:

```
config firewall service category
show
```

This should bring up all of the categories. Check to see that the new one is displayed.

Configuring a new service

Occasionally, the preconfigured list of services will not contain the needed service. There are a few variations in the creation of a service depending upon the protocol type, but the first steps in the creation of the service are common to all the variations.

To create a new service:

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service**
3. Enter a name in the **Name** field for the new service
4. Include any description you would like in the **Comments** field
5. In the **Service Type** field choose between **Firewall** and **Explicit Proxy**.
6. Enable the toggle in the **Show in Service List**. If you can't see the service when you need to select it, it serves very little purpose.
7. For the **Category** field, choose the appropriate category from the **Category** drop down menu. If none is chosen, the **Uncategorized** option will be chosen by default.

Protocol Options

This is the section where the configuration options of the service will differ depending on the type of protocol chosen. (The Step numbers will all continue on from the common step sequence).

The protocol options for **Firewall** service type are:

- **TCP/UDP/SCTP**
- **ICMP**
- **ICMP6**
- **IP**

The protocol options for **Proxy** service type are:

- **ALL**
- **CONNECT**
- **FTP**
- **HTTP**
- **SOCKS-TCP**
- **SOCKS-UDP**

TCP/UDP/SCTP

8. For the **Protocol Type** field, choose **TCP/UDP/SCTP** from the drop down menu
9. For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
 - x.x.x.x - for a specific address
 - x.x.x.x/x - for a subnet
 - x.x.x.x-x.x.x.x - for a range of specific addresses
10. Configure the **Destination Port** by:
 - Select from the drop down menu, **TCP**, **UDP** or **SCTP**
 - Enter the low end to the port range in the field indicated by grayed out **Low**.
 - Enter the high end of the port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
 - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
 - Rows can be removed by using the trash can symbol at the end of the row
11. If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
 - The **Src Port** will match up with a **Destination Port**
 - **Src Ports** cannot be configured without there being a value for the **Destination Port**
 - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
12. Select **OK** to confirm the configuration

Example

Example settings for a TCP protocol service. In this case, it is for an administrative connection to web servers on the DMZ. The protocol used is HTTPS which would normally use port 443, but that is already in use by another service such as Admin access to the firewall or an SSL-VPN connection.

Field	Value
Name	Example.com_WebAdmin
Comments	Admin connection to Example.com Website
Service Type	Firewall
Show in Service List	enabled
Category	Web Access
Protocol Options	
Protocol Type	TCP/UDP/SCTP
IP/FQDN	<left blank>

Field	Value
Destination Port	<ul style="list-style-type: none"> • Protocol: TCP • Low: 4300 • High: <left blank>
Specify Source Ports	<disabled>

Creating a new TCP/UDP/SCTP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit Example.com_WebAdmin
set comment "Admin connection to Example.com Website"
set category Web Access
set protocol TCP/UDP/SCTP
set tcp-portrange 4300
end
end
```

ICMP / ICMP6

8. For the **Protocol Type** field, choose **ICMP** or **ICMP6** from the drop down menu
9. In the **Type** field enter the appropriate type number based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
10. In the **Code** field enter the appropriate code number for the type, if applicable, based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
11. Select **OK** to confirm the configuration

Example

Example settings for an ICMP.service. In this case it has been set up for some special testing of ICMP packets.

Field	Value
Name	ICMP test #4
Comments	For testing of proprietary network scanner
Service Type	Firewall
Show in Service List	enabled
Category	Network Services
Protocol Options	

Field	Value
Protocol Type	ICMP
Type	7
Code	<left blank>

Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
  edit ICMP test4
    set comment "For testing of proprietary network scanner"
    set category Network Services
    set protocol ICMP
    set icmptype 7
  end
end
```

IP

- For the **Protocol Type** field, choose **IP** from the drop down menu
- In the **Protocol Number** field enter the numeric value based on the information found in ["Protocol Number" on page 1](#)
- Select **OK** to confirm the configuration

Example

Example settings for an IP.service. In this case it has been set up to communicate via an old protocol called QNX

Field	Value
Name	QNX
Comments	For QNX communications to the Development Lab
Service Type	Firewall
Show in Service List	enabled
Category	Uncategorized
Protocol Options	
Protocol Type	IP
Protocol Number	106

Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit ICMP test4
    set comment "For QNX communications to the Development Lab "
    set protocol IP
    set icmptype 106
end
end
```

In the CLI examples, the fields for **Show in Service List**, **Service Type** and in the example for IP, **Category** were not set because the values that they would have been set to were the default values and were already correctly set.

ALL/CONNECT/FTP/HTTP/SOCKS-TCP/SOCKS-UDP

These options are available only if the **Service Type** is set to **Explicit Proxy**.

8. For the **Protocol Type** field, choose one of the following from the drop down menu:
 - **ALL**
 - **CONNECT**
 - **FTP**
 - **HTTP**
 - **SOCKS-TCP**
 - **SOCKS-UDP**
9. For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
 - x.x.x.x - for a specific address
 - x.x.x.x/x - for a subnet
 - x.x.x.x-x.x.x.x - for a range of specific addresses
10. Configure the **Destination Port** by:
 - Enter the low end to the TCP port range in the field indicated by grayed out **Low**.
 - Enter the high end of the TCP port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
 - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
 - Rows can be removed by using the trash can symbol at the end of the row
11. If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
 - The **Src Port** will match up with a **Destination Port**
 - **Src Ports** cannot be configured without there being a value for the **Destination Port**
 - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
12. Select **OK** to confirm the configuration

Specific Addresses in TCP/UDP/SCTP

In the TCP/UDP/SCTP services it is also possible to set the parameter for a specific IP or Fully Qualified Domain Name address. The IP/FQDN field refers to the destination address of the traffic, not the source. This means for example, that you can set up a custom service that will describe in a policy the TCP traffic over port 80 going to the web site example.com, but you cannot set up a service that describes the TCP traffic over port 80 that is coming from the computer with the address 192.168.29.59.

Service Groups

Just like some of the other firewall components, services can also be bundled into groups for ease of administration.

Creating a ServiceGroup

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service Group**
3. Input a **Group Name** to describe the services being grouped
4. Input any additional information in the **Comments** field.
5. Choose a **Type** of group. The options are **Firewall** or **Explicit Proxy**.
6. Add to the list of **Members** from the drop down menu. Using the + sign beside the field will allow the addition of multiple services.
7. Press **OK**.

Example

Example of a New Service Group:

Field	Value
Group Name	Authentication Services
Comments	Services used in Authentication
Type	Firewall
Members	<ul style="list-style-type: none">• Kerberos• LDAP• LDAP_UDP• RADIUS

Firewall schedules

Firewall schedules control when policies are in effect. When you add a security policy on a FortiGate unit you need to set a schedule to determine the time frame in which that the policy will be functioning. While it is not set by default, the normal schedule would be always. This would mean that the policy that has been created is always function and always policing the traffic going through the FortiGate. The time component of the schedule is based on a 24 hour clock notation or military time as some people would say.

There are two types of schedules: One-time schedules and recurring schedules.

One-time schedule object

One-Time schedules are in effect only once for the period of time specified in the schedule. This can be useful for testing to limit how long a policy will be in effect in case it is not removed, or it can be used for isolated events such as a conference where you will only need a temporary infrastructure change for a few days.

The time frame for a One-time schedule is configured by using a start time which includes, Year | Month | Day | Hour | Minute and a Stop time which includes the same variables. So while the frequency of the schedule is only once it can last anywhere from 1 minute to multiple years.

Configuring a One-time schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **One-time**.
4. Input a **Name** for the schedule object.
5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. Choose a **Start Date**.
Selecting the field with the mouse will bring up a interactive calendar graphic that will allow the user to select the date. The date can also be typed in using the format YYYY/MM/DD.
7. Choose a **Start Time**.
The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.
6. Choose an **End Date**.
Configuration is the same as **Start Date**.
8. Choose a **Stop Time**.
Configuration is the same as **Start Time**.
9. Enable/Disable **Pre-expiration event log**.
This configures the system to create an event log 1 to 100 days before the **End Date** as a warning in case the schedule needs to be extended.
10. If the **Pre-expiration event log** is enabled, set the value for **Number of days before**.
11. Press **OK**.

Example: Firewall Schedule - One-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	One-time
Name	NewYearsEve_Maintenance
Start Date	2014/12/31 <use the built in calendar>
End Date	2015/01/01 <use the built in calendar>
Start Time	Hour: 23, Minute: 0
Stop Time	Hour: 1Minute: 0
Pre-expiration event log	<disable>

4. Select **OK**.

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule onetime
edit maintenance_window
set start 23:00 2012/12/31
set end 01:00 2013/01/01
next
end
```

To verify that the schedule was added correctly:

1. Enter the following CLI command:

```
config firewall schedule onetime
edit <the name of the schedule you wish to verify>
show full-configuration
```

Recurring schedule object

Recurring schedules are in effect repeatedly at specified times of specified days of the week. The Recurring schedule is based on a repeating cycle of the days of the week as opposed to every x days or days of the month. This means that you can configure the schedule to be in effect on Tuesday, Thursday, and Saturday but not every 2 days or on odd numbered days of the month.

If a recurring schedule has a stop time that is earlier than the start time, the schedule will take effect at the start time but end at the stop time on the next day. You can use this technique to create recurring schedules that run from one day to the next.

Configuring a Recurring schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **Recurring**.
4. Input a **Name** for the schedule object.
5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. From the **Days** options, choose the day of the week that you would like this schedule to apply to. The schedule will be in effect on the days of the week that have a check mark in the checkbox to the left of the name of the weekday.
7. If the scheduled time is the whole day, leave the **All Day** toggle switch enabled. If the schedule is for specific times during the day, disable the **All Day** toggle switch.
8. If the All Day option is disabled, choose a **Start Time**.
The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.
7. Choose a **Stop Time**.
Configuration is the same as **Start Time**.
8. Press **OK**.

Because recurring schedules do not work with DENY policies, the strategy when designing a schedule should *not* be to determine when users cannot access a policy but to build the schedules around when it *is* possible to access the policy.

Example: Firewall Schedule - Recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 9, Minute = 0
Stop Time	Hour = 12, Minute = 0

4. Select **OK**.

5. Create a second new schedule.

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 13, Minute = 0
Stop Time	Hour = 18, Minute = 0

6. Select **OK**.

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule recurring
edit Morning_Business_Hours
set day monday tuesday wednesday thursday friday
set start 09:00
set end 12:00
end
```

2. Enter the following CLI command:

```
config firewall schedule recurring
edit Afternoon_Business_Hours
set day monday tuesday wednesday thursday friday
set start 13:00
set end 18:00
end
```

To verify that the schedule was added correctly:

1. Enter the following CLI command:

```
config firewall schedule recurring
edit <the name of the schedule you wish to verify>
```

```
show full-configuration
```

Schedule Groups

You can organize multiple firewall schedules into a schedule group to simplify your security policy list. The schedule parameter in the policy configuration does not allow for the entering of multiple schedules into a single policy so if you have a combination of time frames that you want to schedule the policy for then the best approach, rather than making multiple policies is to use a schedule group.

Creating a Schedule Group object

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule Group**
3. Input a **Name** for the schedule object.
4. In the **Members** field, select the "+" to bring forth the panel for selecting entries.
5. Press **OK**.

Example

Your Internet policy allows employees to visit Social Media sites from company computers but not during what is considered working hours. The offices are open a few hours before working hours and the doors are not locked until a few hours after official closing so work hours are from 9 to 5 with a lunch break from Noon to 1:00 p.m.

Your approach is to block the traffic between 9 and noon and between 1:00 p.m. and 5:00 p.m. This means you will need two schedules for a single policy and the schedule group handles this for you. Schedule groups can contain both recurring and one-time schedules. Schedule groups cannot contain other schedule groups.

Schedule expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this option is set to disable.

A few further settings are needed to make this work.

```
config firewall policy
  edit ID
    set firewall-session-dirty check-new
  end

config system settings
  set firewall-session-dirty check-policy-option
end
```

The Policy window will indicate when a policy has become invalid due to its schedule parameters referring only to times in the past.

Firewall-session-dirty setting

The firewall-session-dirty setting has three options

<code>check-all</code>	CPU flushes all current sessions and re-evaluates them. [default]
<code>check-new</code>	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
<code>check-policy-option</code>	Use the option selected in the firewall-session-dirty field of the firewall policy (check-all or check-new, as above, but per policy).

Secure Web Gateway, WAN Optimization, Web Caching and WCCP

You can use FortiGate WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers. You can also use the FortiGate unit as an explicit FTP and web proxy server. If your FortiGate unit supports web caching, you can also add web caching to any HTTP sessions including WAN optimization, explicit web proxy and other HTTP sessions.

the next sections of this document describes how FortiGate WAN optimization, web caching, explicit web proxy, explicit FTP proxy and WCCP work and also describes how to configure these features.

Before you begin

Before you begin to configure WAN optimization, Web caching, explicit proxies or WCCP, take a moment to note the following:

FortiGate models that support WAN optimization

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 Gbytes of internal flash storage. All of these storage locations can provide similar web caching and byte caching performance. If you add more than one storage location (for example, by creating multiple partitions on a storage device, by using more than one FSM, or by using an FSM and AMC hard disk in the same FortiGate unit) you can configure different storage locations for web caching and byte caching.

Distributing WAN optimization, explicit proxy, and web caching to multiple CPU Cores

By default WAN optimization, explicit proxy and web caching is handled by half of the CPU cores in a FortiGate unit. For example, if your FortiGate unit has 4 CPU cores, by default two will be used for WAN optimization,

explicit proxy and web caching. You can use the following command to change the number of CPU cores that are used.

```
config system global
    set wad-worker-count <number>
end
```

The value for <number> can be between 1 and the total number of CPU cores in your FortiGate unit. Adding more cores may enhance WAN optimization, explicit proxy and web caching performance and reduce the performance of other FortiGate systems.

Toggling Disk Usage for logging or wan-opt

Both logging and WAN Optimization use hard disk space to save data. In FortiOS, you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
    set disk-usage {log | wanopt}
end
```

The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the [Feature Platform Matrix](#) for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Visibility** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.

Enabling WAN Optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
Logging	Supported	Not supported	Supported
Report/Historical FortiView	Supported	Not supported	Supported
Firewall Packet Capture (Policy Capture and Interface Capture)	Supported	Not supported	Supported
AV Quarantine	Supported	Not supported	Supported
IPS Packet Capture	Supported.	Not supported	Supported
DLP Archive	Supported	Not supported	Supported
Sandbox DB & Results	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

Example topologies relevant to WAN Optimization

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunneling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunneling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server for both IPv4 and IPv6 traffic and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

Web caching can be applied to any HTTP or HTTPS traffic, this includes normal traffic accepted by a security policy, explicit web proxy traffic, and WAN optimization traffic.

You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

FortiGate units can also apply security profiles to traffic as part of a WAN optimization, explicit web proxy, explicit FTP proxy, web cache and WCCP configuration. Security policies that include any of these options can also include settings to apply all forms of security profiles supported by your FortiGate unit.

Basic WAN optimization topology

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

Security device and WAN optimization topology

FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

You can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In the out of path WAN optimization topology shown below, FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

Out-of-path WAN Optimization topology

In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

Single-purpose WAN optimization topology

The following out-of-path FortiGate units are configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

Out-of-path WAN optimization

One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

The out-of-path FortiGate units can operate in NAT or Transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

Topology for multiple networks

As shown in below, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

WAN optimization among multiple networks

You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

WAN optimization with web caching topology

The topology above is the same as that shown in [WAN optimization with web caching on page 1114](#) with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. You can also add web caching to the FortiGate unit that is protecting the private network. In a similar way, you can add web caching to any WAN Optimization topology.

Explicit Web proxy topologies

You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing of IPv4 and IPv6 web traffic. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

Explicit web proxy topology

If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions. The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

Explicit web proxy with web caching topology

Explicit FTP proxy topologies

You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

Explicit FTP proxy topology

You can also configure reverse explicit FTP proxy. In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

Reverse explicit FTP proxy topology

Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. This includes WAN optimization and explicit web proxy traffic. The network topologies for these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

A typical web-caching topology includes one FortiGate unit that acts as a web cache server. Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

Web caching topology

You can also configure reverse proxy web-caching. In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

Reverse proxy web caching topology

WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

WCCP topology

FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

Inside FortiOS: WAN Optimization

Enterprises deploying FortiOS can leverage WAN optimization to provide fast and secure application responses between locations on a Wide Area Network (WAN). The web caching component of FortiOS WAN optimization extends this protection and performance boost to cloud services.

Centralize without compromising your WAN performance

Many multi-location enterprise environments reduce costs and consolidate resources by centralizing applications or providing applications in the cloud. Efficient and high-speed communication between applications and their users is critical. Remote sites don't always have access to high bandwidth, but users at all sites expect consistent network performance. Minimizing user impact and improving performance is especially vital when applications designed for local area networks (LANs) are on the cloud.

Even applications that work fine on a local LAN, such as Windows File Sharing (CIFS), email exchange (MAPI), and many others, suffer from bandwidth limitations and latency issues when accessed over a WAN. This results in a loss of productivity and a perceived need for expensive network upgrades. FortiOS's WAN Optimization provides an inexpensive and easy way to deploy a solution to this problem.

FortiOS is commonly deployed in central offices, satellite offices, and in the cloud to provide secure communications across a WAN using IPsec or SSL VPN. This installed infrastructure can be leveraged to add more value by using WAN Optimization to accelerate WAN traffic and web caching to accelerate cloud services.

FortiOS WAN Optimization

FortiOS includes license-free WAN Optimization on most current FortiGate devices. WAN Optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwidth management and unmatched consolidated security performance. WAN Optimization reduces your network overhead and removes unnecessary traffic for a better overall performance experience. Efficient use of bandwidth and better application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

Regular bandwidth usage**Improved bandwidth usage with FortiGate protocol optimization**

For example, CIFS, which is a fairly “chatty” protocol, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk’s arrival and acknowledgment before sending the next. This large amount of request/acknowledgement traffic can delay transfers. FortiOS CIFS WAN Optimization removes this chattiness and gets on with the job of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

Web caching

In an enterprise environment, multiple users will often want to get the same content (for example, a sales spreadsheet, a corporate presentation or a PDF from a cloud service, or a software update). With FortiOS Web caching, content from the cloud, from the web or from other sites on the WAN is download once and cached on the local FortiGate device. When other users access the same content they download it from the cache. The result is less bandwidth use and reduced latency for the file requester.

FortiOS web caching also recognizes requests for Windows or MS-Office updates and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users and all subsequent requests for this update are rapidly downloaded from the cache.

Byte caching

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching accelerates multiple downloads of different email messages with the same corporate disclaimer by downloading the disclaimer over the WAN once and then downloading all subsequent disclaimers from a local FortiGate unit. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

Dynamic data chunking

Dynamic data chunking detects and optimizes persistent data chunks in changed files or in data embedded in traffic that uses an unknown protocol. For example, dynamic chunking can cache data in Lotus notes traffic and make the data chunks available for email and other protocols.

Data Deduplication

Byte caching breaks large units of application data, like an email attachment or a file download, into manageable small chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user request a file, the WAN Optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading chunks that it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption. In addition to reducing the amount of data downloaded across the WAN, byte caching is not application specific and assists by accelerating all of the protocols supported by WAN Optimization.

Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

VPN replacement

FortiOS WAN optimization supports secure SSL-encrypted tunnels between FortiGate units on the WAN. Employing secure WAN Optimization tunnels can replace IPsec VPNs between sites. The result is a single, relatively simple configuration that supports optimization and privacy of communication across the WAN and uses FortiGate SSL acceleration to provide high performance.

Road warriors and home workers

The drive to give employees greater flexibility and reduce operational costs has led to more remote workers, both at home and on the road. Whether accessing the office from a hotel, public wireless hotspot, or home, the problem is the same: low bandwidth and high latency harming application performance. WAN Optimization is integrated into FortiClient, which can be installed on PCs and wireless devices to optimize communication between remote workers and their offices.

Reduce your...

- **Capital outlay:** Organizations only need to purchase a single device per location.
- **Licensing costs:** WAN Optimization is included with FortiOS. Additional licenses are not needed.
- **Network complexity:** Small offices that may not have the space or power connections for multiple devices do not need to worry: no additional devices are required.

WAN Optimization Concepts

Client/server architecture

Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. These communication sessions can be open text over the WAN or they can be encrypted by SSL VPN or IPsec VPN.

To optimize these sessions, you can add **WAN optimization security policies** to the **client-side FortiGate unit** to accept sessions from the client network that are destined for the server network. The client-side FortiGate unit is located between the client network and the WAN. WAN optimization security policies include **WAN optimization profiles** that control how the traffic is optimized.

The client-side FortiGate unit must also include the IP address of the **server-side FortiGate unit** in its WAN optimization **peer** configuration. The server-side FortiGate unit is located between the server network and the WAN. The peer configuration allows the client-side FortiGate unit to find the server-side FortiGate unit and attempt to establish a WAN optimization **tunnel** with it.

For the server-side FortiGate unit you must add a security policy with **wanopt** as the **Incoming Interface**. This security policy allows the FortiGate unit to accept WAN optimization sessions from the client-side FortiGate unit. For the server-side FortiGate unit to accept a WAN optimization connection it must have the client-side FortiGate unit in its WAN optimization peer configuration.

WAN optimization profiles are only added to the client-side WAN optimization security policy. The server-side FortiGate unit employs the WAN optimization settings set in the WAN optimization profile on the client-side FortiGate unit.

Client/server architecture

When both peers are identified the FortiGate units attempt to establish a WAN optimization **tunnel** between them. WAN optimization tunnels use port 7810. All optimized data flowing across the WAN between the client-side and server-side FortiGate units use this tunnel. WAN optimization tunnels can be encrypted use SSL encryption to keep the data in the tunnel secure.

Any traffic can be sent through a WAN optimization tunnel. This includes SSL and IPsec VPN traffic. However, instead of configuring SSL or IPsec VPN for this communication you can add SSL encryption using the WAN optimization tunnel.

In addition to basic identification by peer host ID and IP address you can configure WAN optimization **authentication** using certificates and pre-shared keys to improve security. You can also configure FortiGate units

involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

The FortiClient application can act in the same manner as a client-side FortiGate unit to optimize traffic between a computer running FortiClient and a FortiGate unit.

WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

WAN optimization peer and tunnel architecture

To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly “chatty” protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you select the CIFS protocol in a WAN optimization profile, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

If a policy accepts a range of different types of traffic, you can set **Protocol** to **TCP** to apply general optimization techniques to TCP traffic. However, applying this TCP optimization is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper learns these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol

optimization for MAPI you should set the WAN optimization profile to a single port number (usually port 135). Specifying a range of ports may reduce performance.

Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labeling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select **Byte Caching** in a WAN optimization profile.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

Dynamic data chunking for byte caching

Dynamic data chunking can improve byte caching by improving detection of data chunks that are already cached in changed files or in data embedded in traffic using an unknown protocol. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set prefer-chunking dynamic
    end
```

By default dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization “see” different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is **not** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server-side FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server-side FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is similar to source NAT. FortiGate Transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

Configuring Transparent mode

You can configure transparent mode by selecting **Transparent** in a WAN Optimization profile. The profile is added to an active WAN Optimization policy.

When you configure a passive WAN Optimization policy you can accept the active policy transparent setting or you can override the active policy transparent setting. From the GUI you can do this by setting the **Passive Option** as follows:

- **default** use the transparent setting in the WAN Optimization profile added to the active policy (client-side configuration).
- **transparent** impose transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate keep their original source addresses.
- **non-transparent** impose non-transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate have their source address changed to the address of the server-side FortiGate unit interface that sends the packets to the servers.

From the CLI you can use the following command:

```
config firewall policy
  set wanopt-passive-opt {default | transparent | non-transparent}
end
```

Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT or Transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

As well, the FortiGate units can be configured for multiple virtual domain (VDOM) operation. You configure WAN optimization for each VDOM and configure one or both of the units to operate with multiple VDOMs enabled.

If a FortiGate unit or VDOM is operating in Transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

WAN optimization tunnels

All optimized traffic passes between the FortiGate units over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

WAN optimization tunnels

Both plain text and the encrypted tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

Tunnel sharing

You can use the `tunnel-sharing` WAN optimization profile CLI keyword to configure tunnel sharing for WAN optimization rules. Tunnel sharing means multiple WAN optimization sessions share the same tunnel. Tunnel sharing can improve performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Use the following command to configure tunnel sharing for HTTP traffic in a WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set tunnel-sharing {express-shared | private | shared}
    end
```

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-shared` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user's experience with the protocol.

Set `tunnel-sharing` to `shared` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `sharing` and `express-shared` can share the same tunnel.

WAN optimization and user and device identity policies, load balancing and traffic shaping

Please note the following about WAN optimization and firewall policies:

- WAN optimization is not compatible with firewall load balancing.
- WAN optimization is compatible with source and destination NAT options in firewall policies (including firewall virtual IPs). If a virtual IP is added to a policy the traffic that exits the WAN optimization tunnel has its destination address changed to the virtual IPs mapped to IP address and port.
- WAN optimization is compatible with user identity-based and device identity security policies. If a session is allowed after authentication or device identification the session can be optimized.

Traffic shaping

Traffic shaping works for WAN optimization traffic that is not in a WAN optimization tunnel. So traffic accepted by a WAN optimization security policy on a client-side FortiGate unit can be shaped on ingress. However, when the traffic enters the WAN optimization tunnel, traffic shaping is not applied.

In manual mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- Traffic shaping cannot be applied to traffic on the server-side FortiGate unit.

In active-passive mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- If transparent mode is enabled in the WAN optimization profile, traffic shaping also works as expected on the server-side FortiGate unit.
- If transparent mode is not enabled, traffic shaping works partially on the server-side FortiGate unit.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, only the primary unit stores the byte cache database. This database is not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its byte cache. Rebuilding the byte cache can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate unit that it is participating with in WAN optimization tunnels.

WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization is enabled you will see a reduction in available memory. The reduction increases when more WAN optimization sessions are being processed. If you are thinking of enabling WAN optimization on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by WAN optimization. See "get test {wad | wccpd} <test_level>" for more information.

WAN Optimization Configuration

This chapter describes FortiGate WAN optimization client server architecture and other concepts you need to understand to be able to configure FortiGate WAN optimization.

Manual (peer-to-peer) and active-passive WAN optimization

You can create **manual** (peer-to-peer) and **active-passive** WAN optimization configurations.

In reality, because WAN optimization traffic can only be processed by one CPU core, it is not recommended to increase the number of manual mode peers on the FortiGate unit per VDOM.

Note that the maximum number of manual peers are restricted to 256 per VDOM. However, in Active-Passive configurations, there is no hard-limit to the maximum number of manual peers per VDOM.

Manual (peer to peer) configurations

Manual configurations allow for WAN optimization between one client-side FortiGate unit and one server-side FortiGate unit. To create a manual configuration you add a **manual mode** WAN optimization security policy to the client-side FortiGate unit. The manual mode policy includes the peer ID of a server-side FortiGate unit.

In a manual mode configuration, the client-side peer can only connect to the named server-side peer. When the client-side peer initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization policy; however, you need to add the client peer host ID and IP address to the server-side FortiGate unit peer list.

In addition, from the server-side FortiGate unit CLI you must add an Explicit Proxy security policy with `proxy` set to `wanopt` and the destination interface and network set to the network containing the servers that clients connect to over the WAN optimization tunnel. WAN optimization tunnel requests are accepted by the explicit proxy policy and if the client-side peer is in the server side peer's address list the traffic is forwarded to the servers on the destination network.

Manual mode client-side policy

You must configure manual mode client-side policies from the CLI. From the GUI a manual mode policy has WAN Optimization turned on and includes the following text beside the *WAN optimization* field: *Manual (Profile: <profile-name>. Peer: <peer-name>.*

Add a manual mode policy to the client-side FortiGate unit from the CLI. The policy enables WAN optimization, sets `wanopt-detection` to `off`, and uses the `wanopt-peer` option to specify the server-side peer. The following example uses the default WAN optimization profile.

```
config firewall policy
  edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection off
    set wanopt-profile default
    set wanopt-peer server
  next
end
```

Manual mode server-side explicit proxy policy

The server-side explicit proxy policy allows connections from the WAN optimization tunnel to the server network by setting the proxy type to `wanopt`. You must add policies that set `proxy` to `wanopt` from the CLI and these policies do not appear on the GUI. The policy should look like the following:

```
configure firewall proxy-policy
  edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
  next
end
```

Active-passive configurations

Active-passive WAN optimization requires an **active** WAN optimization policy on the client-side FortiGate unit and a **passive** WAN optimization policy on the server-side FortiGate unit. The server-side FortiGate unit also requires an explicit proxy policy with `proxy` set to `wanopt`.

You can use the passive policy to control WAN optimization address translation by specifying **transparent mode** or non-transparent mode. See [Manual \(peer-to-peer\) and active-passive WAN optimization on page 1125](#). You can also use the passive policy to apply security profiles, web caching, and other FortiGate features at the server-side FortiGate unit. For example, if a server-side FortiGate unit is protecting a web server, the passive policy could enable web caching.

A single passive policy can accept tunnel requests from multiple FortiGate units as long as the server-side FortiGate unit includes their peer IDs and all of the client-side FortiGate units include the server-side peer ID.

Active client-side policy

Add an active policy to the client-side FortiGate unit by turning on **WAN Optimization** and selecting **active**. Then select a WAN optimization **Profile**. From the CLI the policy could look like the following:

```
config firewall policy
  edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection active
    set wanopt-profile default
  next
end
```

Server-side tunnel policy

The server-side requires an explicit proxy policy that sets the `proxy` to `wanopt`. You must add this policy from the CLI and policies with `proxy` set to `wanopt` do not appear on the GUI. From the CLI the policy could look like the following:

```
configure firewall proxy-policy
  edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
  next
end
```

Server-side passive policy

Add a passive policy to the server-side FortiGate unit by selecting **Enable WAN Optimization** and selecting **passive**. Then set the **Passive Option** to **transparent**. From the CLI the policy could look like the following:

```
config firewall policy
  edit 2
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set wanopt enable
    set wanopt-detection passive
```

```
set wanopt-passive-opt transparent
next
```

WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile you can select the protocols to be optimized and for each protocol you can enable SSL offloading (if supported), secure tunneling, byte caching and set the port or port range the protocol uses. You can also enable transparent mode and optionally select an authentication group. You can edit the default WAN optimization profile or create new ones.

To configure a WAN optimization profile go to **WAN Opt. & Cache > Profiles** and edit a profile or create a new one.

Configuring a WAN optimization profile

From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
edit new-profile
config http
set status enable
end
```

Transparent Mode	<p>Servers receiving packets after WAN optimization “see” different source addresses depending on whether or not you select Transparent Mode.</p> <p>For more information, see WAN optimization profiles on page 1128.</p>
Authentication Group	<p>Select this option and select an authentication group so that the client and server-side FortiGate units must authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select Secure Tunneling for any protocol.</p> <p>You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel. For more information, see .</p>
Protocol	<p>Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for the selected protocols. See WAN optimization profiles on page 1128.</p> <p>Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.</p>

SSL Offloading	<p>Select to apply SSL offloading for HTTPS or other SSL traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the security policy to accept SSL-encrypted traffic.</p> <p>If you enable SSL offloading, you must also use the CLI command <code>config firewall ssl-server</code> to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see .</p>
Secure Tunnelling	The WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the profile. For more information, see .
Byte Caching	Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see "Byte caching" .
Port	Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be optimized.

Processing non-HTTP sessions accepted by a WAN optimization profile with HTTP optimization

From the CLI, you can use the following command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

```
config wanopt profile
  edit default
    config http
      set status enable
      set tunnel-non-http {disable | enable}
    end
```

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the following command to specify how a rule handles such HTTP sessions.

```
config wanopt profile
  edit default
    config http
      set status enable
      set unknown-http-version {best-effort | reject | tunnel}
    end
```

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the

FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to **Monitor > WAN Opt. Monitor**.

WAN optimization monitor

Traffic Summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

Bandwidth Optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

WAN optimization configuration summary

This section includes a client-side and a server-side WAN Optimization configuration summary.:

Client-side configuration summary

WAN optimization profile

Enter the following command to view WAN optimization profile CLI options:

```
tree wanopt profile
-- [profile] --*name (36)
  |- transparent
  |- comments
  |- auth-group (36)
  |- <http> -- status
    |- secure-tunnel
```

```

        +- ssl-port (1,65535)

```

Local host ID and peer settings

```

config wanopt settings
    set host-id client
end
config wanopt peer
    edit server
        set ip 10.10.2.82
    end

```

Security policies

Two client-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on the client-side

```

config firewall policy

```

```

edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection active <<< set the mode to active/passive
    set wanopt-profile "default" <<< select the wanopt profile
next
end

```

Manual mode on the client-side

```

config firewall policy
edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection off <<< sets the mode to manual
    set wanopt-profile "default" <<< select the wanopt profile
    set wanopt-peer "server" <<< set the only peer to do wanopt
                                (required for manual mode)
                                with
next
end

```

server-side configuration summary

Local host ID and peer settings

```

config wanopt settings
    set host-id server
end
config wanopt peer
edit client
    set ip 10.10.2.81
end

```

Security policies

Two server-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on server-side

```

config firewall policy
edit 2 <<< the passive mode policy
    set srcintf wan1
    set dstintf internal

```

```

        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set wanopt enable
        set wanopt-detection passive
        set wanopt-passive-opt transparent
    end
    config firewall proxy-policy
        edit 3 <<< policy that accepts wanopt tunnel connections from the server
            set proxy wanopt <<< wanopt proxy type
            set dstintf internal
            set srcaddr all
            set dstaddr server-subnet
            set action accept
            set schedule always
            set service ALL
        next
    end

```

Manual mode on server-side

```

    config firewall proxy-policy
        edit 3 <<< policy that accepts wanopt tunnel connections from the client
            set proxy wanopt <<< wanopt proxy type
            set dstintf internal
            set srcaddr all
            set dstaddr server-subnet
            set action accept
            set schedule always
            set service ALL
        next
    end

```

Best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See [Best practices on page 1133](#).
- Active-passive HA is the recommended HA configuration for WAN optimization. See [Best practices on page 1133](#).
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. See .
- Set the explicit proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit web proxy. See .
- Set the explicit FTP proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit FTP proxy. See .
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy. See .

Example Basic manual (peer-to-peer) WAN optimization configuration

In a manual (peer to peer) configuration the WAN optimization tunnel can be set up between one client-side FortiGate unit and one server-side FortiGate unit. The peer ID of the server-side FortiGate unit is added to the client-side WAN optimization policy. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include information that allows the server-side FortiGate unit to determine that it is a manual tunnel request. The server-side FortiGate unit does not require a WAN optimization profile; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and from the CLI an explicit proxy policy to accept WAN optimization tunnel connections.

In a manual WAN optimization configuration, you create a manual WAN optimization security policy on the client-side FortiGate unit. To do this you must use the CLI to set `wanopt-detection` to `off` and to add the peer host ID of the server-side FortiGate unit to the WAN optimization security policy.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-Fgt with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Server_Fgt with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

This example customizes the default WAN optimization profile on the client-side FortiGate unit and adds it to the WAN optimization policy. You can also create a new WAN optimization profile.

Example manual (peer-to-peer) topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
 - Add peers.
 - Configure the default WAN optimization profile to optimize HTTP traffic.
 - Add a manual WAN optimization security policy.
2. Configure the server-side FortiGate unit:
 - Add peers.
 - Add a WAN optimization tunnel policy.

Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example configuration from the web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add the server-side FortiGate unit **Peer Host ID** and **IP Address** for the server-side FortiGate:

Peer Host ID	Server-Fgt
IP Address	192.168.30.12

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Go to **WAN Opt. & Cache > Profiles** and edit the default profile.
8. Select **Transparent Mode**.
9. Under Protocol, select **HTTP** and for HTTP select **Byte Caching**. Leave the HTTP **Port** set to 80.
10. Select **Apply** to save your changes.
11. Go to **Policy & Objects > IPv4 Policy** and add a WAN optimization security policy to the client-side FortiGate unit that accepts traffic to be optimized:

Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	all
Schedule	always
Service	ALL

Action	ACCEPT
---------------	--------

12. Select **Enable WAN Optimization** and configure the following settings:

Enable WAN Optimization	active
Profile	default

13. Select **OK**.

14. Edit the policy from the CLI to turn off `wanopt-detection`, add the peer ID of the server-side FortiGate unit, and the default WAN optimization profile. The following example assumes the ID of the policy is 5:

```
config firewall policy
edit 5
set wanopt-detection off
set wanopt-peer Server-Fgt
set wanopt-profile default
end
```

When you set the detection mode to `off` the policy becomes a manual mode WAN optimization policy. On the web-based manager the WAN optimization part of the policy changes to the following:

Enable WAN Optimization	Manual (Profile: default, Peer: Peer-Fgt-2)
--------------------------------	---

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply**.
 3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.20.34.12

4. Select **OK**.
 5. Enter the following CLI command to add an explicit proxy policy to accept WAN optimization tunnel connections.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
  set ip 192.168.30.12
end
```

3. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
  set type ipmask
  set subnet 172.20.120.0 255.255.255.0
  set associated-interface port1
end
```

4. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
  set type ipmask
  set subnet 192.168.10.0 255.255.255.0
  set associated-interface port2
end
```

5. Edit the default WAN optimization profile, select transparent mode, enable HTTP WAN optimization and enable byte caching for HTTP. Leave the HTTP Port set to 80.

```
config wanopt profile
  edit default
  set transparent enable
  config http
    set status enable
    set byte-caching enable
  end
end
```

6. Add a WAN optimization security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 0
  set srcintf port1
  set dstintf port2
  set srcaddr all
  set dstaddr all
  set action accept
  set service ALL
  set schedule always
```

```
set wanopt enable
set wanopt-profile default
set wanopt-detection off
set wanopt-peer Server-Fgt
end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
edit Client-Fgt
set ip 192.168.30.12
end
```

3. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the client-side FortiGate unit is accepting traffic for the 192.168.10.0 network. You can do this by checking the policy monitor (**Monitor > Firewall User Monitor**). Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating.

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web-servers id=100 ip=192.168.30.12

      bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example Active-passive WAN optimization

In active-passive WAN optimization you add an active WAN optimization policy to the client-side FortiGate unit and you add a WAN optimization tunnel policy and a passive WAN optimization policy to the server-side FortiGate unit.

The active policy accepts the traffic to be optimized and sends it down the WAN optimization tunnel to the server-side FortiGate unit. The active policy can also apply security profiles and other features to traffic before it exits the client-side FortiGate unit.

A tunnel explicit proxy policy on the server-side FortiGate unit allows the server-side FortiGate unit to form a WAN optimization tunnel with the client-side FortiGate unit. The passive WAN optimization policy is required because of the active policy on the client-side FortiGate unit. You can also use the passive policy to apply WAN optimization transparent mode and features such as security profiles, logging, traffic shaping and web caching to the traffic before it exits the server-side FortiGate unit.

Network topology and assumptions

On the client-side FortiGate unit this example configuration includes a WAN optimization profile that optimizes CIFS, HTTP, and FTP traffic and an active WAN optimization policy. The active policy also applies virus scanning to the WAN optimization traffic.

On the server-side FortiGate unit, the passive policy applies application control to the WAN optimization traffic.

In this example, WAN optimization transparent mode is selected in the WAN optimization profile and the passive WAN optimization policy accepts this transparent mode setting. This means that the optimized packets maintain their original source and destination addresses. As a result, routing on the client network must be configured to route packets for the server network to the client-side FortiGate unit. Also the routing configuration on the server network must be able to route packets for the client network to the server-side FortiGate unit.

Example active-passive WAN optimization topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:

- Add peers.
 - Add a WAN optimization profile to optimize CIFS, FTP, and HTTP traffic.
 - Add firewall addresses for the client and web server networks.
 - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit by:
 - Add peers.
 - Add firewall addresses for the client and web server networks.
 - Add a passive WAN optimization policy.
 - Add a WAN optimization tunnel policy.

Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager.

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a Peer Host ID and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic:

Name	Custom-wan-opt-pro
Transparent Mode	Select

6. Select the **CIFS** protocol, select **Byte Caching** and set the **Port** to 445.
7. Select the **FTP** protocol, select **Byte Caching** and set the **Port** to 21.
8. Select the **HTTP** protocol, select **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range

Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

11. Select **Create New** to add an address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP FTP SMB
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Custom-wan-opt-pro

14. Turn on Antivirus and select the **default** antivirus profile.

15. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.

5. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.100-172.20.120.200
Interface	port1

6. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Select **OK**.

8. Select **Policy & Objects > IPv4 Policy** and select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

9. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

10. Select **OK**.

11. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
    edit Server-Fgt
        set ip 192.168.20.1
    end
```

3. Add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic.

```
config wanopt profile
    edit Custom-wan-opt-pro
        config cifs
            set status enable
            set byte-caching enable
            set port 445
        end
        config http
            set status enable
            set byte-caching enable
            set port 80
        end
        config ftp
            set status enable
            set byte-caching enable
            set port 21
        end
    end
```

4. Add a firewall address for the client network.

```
config firewall address
    edit Client-Net
        set type iprange
        set start-ip 172.20.120.100
        set end-ip 172.20.120.200
```

```

        set associated-interface port1
    end

```

5. Add a firewall address for the web server network.

```

config firewall address
    edit Web-Server-Net
        set type ipmask
        set subnet 192.168.10.0 255.255.255.0
        set associated-interface port2
    end

```

6. Add an active WAN optimization security policy that applies virus scanning:

```

config firewall policy
    edit 0
        set srcintf port1
        set dstintf port2
        set srcaddr Client-net
        set dstaddr Web-Server-Net
        set action accept
        set service HTTP FTP SMB
        set schedule always
        set wanopt enable
        set wanopt-detection active
        set wanopt-profile Custom-wan-opt-pro
    end

```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```

config wanopt settings
    set host-id Server-Fgt
end

```

2. Add the client-side Local Host ID to the server-side peer list:

```

config wanopt peer
    edit Client-Fgt
        set ip 172.20.120.1
    end

```

3. Add a firewall address for the client network.

```

config firewall address
    edit Client-Net
        set type iprange
        set start-ip 172.20.120.100
        set end-ip 172.20.120.200
        set associated-interface port1
    end

```

4. Add a firewall address for the web server network.

```

config firewall address
    edit Web-Server-Net
        set type ipmask
        set subnet 192.168.10.0 255.255.255.0
        set associated-interface port2
    end

```

5. Add a passive WAN optimization policy.

```

config firewall policy
    edit 0
        set srcintf port1
        set dstintf port2

```

```
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-detection passive
set wanopt-passive-opt default
end
```

6. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include security profiles. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```
diagnose wad tunnel list

Tunnel: id=139 type=auto
```

```

vd=0 shared=no uses=0 state=1
peer name= id=0 ip=unknown
SSL-secured-tunnel=no auth-grp=test
bytes_in=744 bytes_out=76

Tunnel: id=141 type=auto
vd=0 shared=no uses=0 state=1
peer name= id=0 ip=unknown
SSL-secured-tunnel=no auth-grp=test
bytes_in=727 bytes_out=76

Tunnel: id=142 type=auto
vd=0 shared=no uses=0 state=1
peer name= id=0 ip=unknown
SSL-secured-tunnel=no auth-grp=test
bytes_in=727 bytes_out=76

Tunnels total=3 manual=0 auto=3

```

Example Adding secure tunneling to an active-passive WAN optimization configuration

This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has **Peer Acceptance** set to **Accept any Peer**. An active policy is added to the client-side FortiGate unit and a passive policy to the server-side FortiGate unit. The active policy includes a profile that performs secure tunneling, optimizes HTTP traffic, and uses Transparent Mode and byte caching.

The authentication group is named **Auth-Secure-Tunnel** and the password for the pre-shared key is **2345678**. The topology for this example is shown below. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see .

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-net with a WAN IP address of 172.30.120.1. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web-servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

Example active-passive WAN optimization and secure tunneling topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
 - Add peers.
 - Add an authentication group.
 - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit.

- Add peers.
- Add the same authentication group
- Add a passive WAN optimization policy that applies application control.
- Add a WAN optimization tunnel policy.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

Local Host ID	Client-Fgt
----------------------	------------

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** to add the authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
7. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile that enables secure tunneling and includes the authentication group:

Name	Secure-wan-op-pro
Transparent Mode	Select
Authentication Group	Auth-Secure-tunnel

8. Select the **HTTP** protocol, select Secure Tunneling and **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

11. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP
Action	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	active
Profile	Secure-wan-opt-pro

14. Select **OK**.

To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

Local Host ID	Server-Fgt
----------------------	------------

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** and add an authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select **OK**.
7. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

8. Select **Create New** to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

9. Select **OK**.
10. Select **Create New** to add a passive WAN optimization policy that applies application control.

Incoming Interface	port2
Source Address	Client-Net

Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

11. Turn on **WAN Optimization** and configure the following settings:

WAN Optimization	passive
Passive Option	default

12. Select **OK**.

13. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
    edit Server-Fgt
        set ip 192.168.20.1
    end
```

3. Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
    edit Auth-Secure-Tunnel
        set auth-method psk
        set psk 2345678
    end
```

Leave `peer-accept` at its default value.

4. Add a WAN optimization profile that enables secure tunneling and includes the authentication group, enables HTTP protocol optimization, and enables secure tunneling and byte caching for HTTP traffic:

```
config wanopt profile
edit Secure-wan-op-pro
set auth-group Auth-Secure-Tunnel
config http
set status enable
set secure-tunnel enable
set byte-caching enable
set port 80
end
end
```

5. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

6. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

7. Add an active WAN optimization security policy that includes the WAN optimization profile that enables secure tunneling and that applies virus scanning:

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service HTTP
set schedule always
set wanopt enable
set wanopt-detection active
set wanopt-profile Secure-wan-opt-pro
end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
```

```
edit Client-Fgt
set ip 172.20.120.1
end
```

3. Add an authentication group to be used for secure tunneling:

```
config wanopt auth-group
edit Auth-Secure-Tunnel
set auth-method psk
set psk 2345678
end
```

Leave `peer-accept` at its default value.

4. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

5. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

6. Add a passive WAN optimization policy.

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-detection passive
set wanopt-passive-opt default
end
```

7. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

Peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see [Basic WAN optimization peer requirements on page 1154](#).

- The peer must have a unique host ID.
- Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.
- All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate. Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see [Basic WAN optimization peer requirements on page 1154](#).

How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see [How FortiGate units process tunnel requests for peer authentication on page 1154](#) and [How FortiGate units process tunnel requests for peer authentication on page 1154](#).

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see [How FortiGate units process tunnel requests for peer authentication on page 1154](#).

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
- If the setting is **Accept Any Peer**, the authentication is successful.
- If the setting is **Specify Peer**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
- If the setting is **Accept Defined Peers**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

To configure WAN optimization peers - web-based manager:

1. Go to **WAN Opt. & Cache > Peers**.
2. For **Local Host ID**, enter the local host ID of **this** FortiGate unit and select **Apply**. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its **peer** host ID.

The local or host ID can contain up to 25 characters and can include spaces.

3. Select **Create New** to add a new peer.
4. For **Peer Host ID**, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.
5. For **IP Address**, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.
6. Select **OK**.

To configure WAN optimization peers - CLI:

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1. Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
  set host-id HQ_peer
end
```

2. Enter the following commands to add three peers.

```
config wanopt peer
  edit Wan_opt_peer_1
    set ip 172.20.120.100
  next
  edit Wan_opt_peer_2
    set ip 172.30.120.100
  next
  edit Wan_opt_peer_3
    set ip 172.40.120.100
end
```

Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling.

To add authentication groups, go to **WAN Opt. & Cache > Authentication Groups**.

To add an authentication group - web-based manager:

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New**.
3. Add a **Name** for the authentication group.

You will select this name when you add the authentication group to a WAN optimization rule.

4. Select the **Authentication Method**.

Select **Certificate** if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to **System > Certificates**.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

Select **Pre-shared key** if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the **Password** (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5. Configure **Peer Acceptance** for the authentication group.

Select **Accept Any Peer** if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used for WAN optimization with FortiGate units that do not have static IP addresses, for example units that use DHCP.

Select **Accept Defined Peers** if you want to authenticate with peers added to the peer list only.

Select **Specify Peer** and select one of the peers added to the peer list to authenticate with the selected peer only.

6. Select **OK**.

7. Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

To add an authentication group that uses a certificate- CLI:

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert Example_Cert
    set peer-accept defined
  end
```

To add an authentication group that uses a pre-shared key - CLI:

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
  edit auth_peer
    set auth-method psk
    set psk 123456
    set peer-accept one
    set peer Server_net
  end
```

To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the **Peer Host IDs** or **IP Addresses** of the peers that you want to perform WAN optimization with. This setting is most often used with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to **Pre-shared key**. You must add the same password to all FortiGate units using this authentication group.

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New** to add a new authentication group.
3. Configure the authentication group:

Name	Specify any name.
Authentication Method	Pre-shared key
Password	Enter a pre-shared key.
Peer Acceptance	Accept Any Peer

To add an authentication group that accepts WAN optimization connections from any peer - CLI:

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert WAN_Cert
    set peer-accept any
  end
```

Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select **Enable Secure Tunnel** in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The **Peer Acceptance** setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select **Enable Secure Tunnel** only in the active rule. In peer-to-peer WAN optimization you select **Enable Secure Tunnel** in the WAN optimization rule on both FortiGate units. For information about active-passive and peer-to-peer WAN optimization, see

For a secure tunneling configuration example, see .

Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer's name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to **WAN Opt. & Cache > Peer Monitor**.

Web Cache Concepts

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. See [RFC 2616](#) for information about web caching for HTTP 1.1.

Web caching supports caching of Flash content over HTTP but does not cache audio and video streams including Flash videos and streaming content that use native streaming protocols such as RTMP.

The first time a file is received by web caching it is cached in the format it is received in, whether it be compressed or uncompressed. When the same file is requested by a client but in a different compression format, the cached file is converted to the new compressed format before being sent to the client.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

Turning on web caching for HTTP and HTTPS traffic

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes IPv4, IPv6, WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the

Internet.

- Reduce the load on a public facing web server by caching objects on the FortiGate unit. This is a reverse proxy with web caching configuration. Do this by selecting the web cache option for a security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.
- Combine web caching with WAN optimization. You can enable web caching in any WAN optimization security policy. This includes manual, active, and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other. For optimum performance you can enable web caching on both the client-side and server-side FortiGate units. In this way only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

One important use for web caching is to cache software updates (for example, Windows Updates or iOS updates). When updates occur a large number of users may all be trying to download these updates at the same time. Caching these updates will be a major performance improvement and also have a potentially large impact on reducing Internet bandwidth use. You may want to adjust the maximum cache object size to make sure these updates are cached. See [Turning on web caching for HTTP and HTTPS traffic on page 1159](#).

Turning on web caching for HTTPS traffic

Web caching can also cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack.

You enable HTTPS web caching from the CLI in a security policy or an explicit proxy policy that accepts the traffic to be cached using `webcache-https`. For a firewall policy:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end
```

For an explicit web proxy policy:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    .
    .
    .
    set webcache enable
    set webcache-https enable
```

```

.
.
.
end

```

The `webcache-https` field is available only if `webcache` is enabled.

Web caching for HTTPS traffic is not supported if WAN optimization or FTP proxy is enabled: i.e., if `srcintf` is `ftp-proxy` or `wanopt`.

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`. This option is available for both firewall policies and explicit web proxy policies.

```

config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end

```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with a certificate that you imported into the FortiGate unit. You can add certificates using the following command:

```

config firewall ssl-server
  edit corporate-server
    set ip <Web-Server-IP>
    set port 443
    set ssl-mode { full | half }
    set ssl-cert <Web-Server-Cert>
  end

```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is a web server certificate imported into the FortiGate unit.

The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

You can add multiple SSL server certificates in this way. When web caching processing an SSL stream if it can find a certificate that matches the web server IP address and port of one of the added SSL servers; that certificate is used to encrypt the SSL traffic before sending it to the client. As a result the client does not generate SSL certificate errors.

Web caching uses the FortiGate unit's FortiASIC to accelerate SSL decryption/encryption performance.

Full mode SSL server configuration

The `ssl-mode` option determines whether the SSL server operates in half or full mode. In full mode the FortiGate unit performs both decryption and encryption of the HTTPS traffic. The full mode sequence is shown below.

Full mode SSL server configuration

In full mode the FortiGate unit is acting as a man in the middle, decrypting and encrypting the traffic. So both the client and the web server see encrypted packets.

Usually the port of the encrypted HTTPS traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. This port is not altered by the SSL Server. So for example, if the SSL Server receives HTTPS traffic on port 443, the re-encrypted traffic forwarded to the FortiGate unit to the server or client will still use port 443.

Half mode SSL server configuration

In half mode, the FortiGate unit only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets.

Half mode SSL server configuration

In half mode, the FortiGate unit is acting like an SSL accelerator, offloading HTTPS decryption from the web server to the FortiGate unit. Since FortiGate units can accelerate SSL processing, the end result could be improved web site performance.

Usually the port of the encrypted traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. No matter what port is used for the HTTPS traffic, the decrypted HTTP traffic uses port 80.

Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443. So web caching caches all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable security profiles for the security policy and configure a proxy options profile to that looks for HTTP and HTTPS traffic on other TCP ports. To configure a proxy options profile go to **Network > Explicit Proxy**.

Setting the HTTP port to **Any** in a proxy options profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

Web caching and HA

You can configure web caching on a FortiGate HA cluster. The recommended best practice HA configuration for web caching is active-passive mode. When the cluster is operating, all web caching sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance web caching sessions.

In a cluster, only the primary unit stores the web cache database. The databases is not synchronized to the subordinate units. So, after a failover, the new primary unit must build its web cache.

Web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency, web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, web caching requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When web caching is enabled you will see a reduction in available memory. The reduction increases when more web caching sessions are being processed. If you are thinking of enabling web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by web caching. See for more information.

Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to **WAN Opt. & Cache > Settings**.

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see [RFC 2616](#).

Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

For most web traffic the default maximum cache object size is recommended. However, since web caching can also cache larger objects such as Windows updates, Mac OS updates, iOS updates or other updates delivered using HTTP you might want to increase the object size to make sure these updates are cached. Caching these updates can save a lot of Internet bandwidth and improve performance when major updates are released by these vendors.

Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the **Fresh Factor** the less often the checks occur.

For example, if you set the **Max TTL** value and **Default TTL** to 7200 minutes (5 days) and set the **Fresh Factor** to 20, the web cache check the cached objects 5 times before they expire, but if you set the **Fresh Factor** to 100, the web cache will check once.

Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Ignore

Select the following options to ignore some web caching features.

If-modified-since	By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object. Enable ignoring if-modified-since to override this behavior.
HTTP 1.1 conditionals	HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see RFC 2616 . Enable ignoring HTTP 1.1 Conditionals to override this behavior.
Pragma-no-cache	Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh. Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.
IE Reload	Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select Refresh . When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object. Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

Cache Expired Objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

Revalidated Pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting **Revalidate Pragma-no-cache**.

When you select **Revalidate Pragma-no-cache**, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, **Revalidate Pragma-no-cache** is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the **Revalidate pragma-no-cache** option.

Web Cache Configuration

Forwarding URLs to forwarding servers and exempting web sites from web caching

You can go to **Network > Explicit Proxy** and use the URL match list to forward URL patterns to forwarding servers and create a list of URLs that are exempt from web caching.

Forwarding URLs and URL patterns to forwarding servers

As part of configuring the explicit web proxy you can configure proxy chaining by adding web proxy forwarding servers. See [Proxy chaining \(web proxy forwarding servers\)](#).

You can then use the URL match list to always forward explicit web proxy traffic destined for configured URLs or URL patterns to one of these forwarding servers. For example, you might want to forward all traffic for a specific country to a proxy server located in that country.

To forward traffic destined for a URL to a forwarding server that you have already added, go to **Network > Explicit Proxy** and select **Create New**. Add a name for the URL match entry and enter the URL or URL pattern. You can use wildcards such as * and ? and you can use a numeric IP address. Select **Forward to Server** and select a web proxy forwarding server from the list.

You can also exempt the URL or URL pattern from web caching.

Use the following command to forward all .ca traffic to a proxy server and all .com traffic to another proxy server.

```
config web-proxy url-match
  edit "com"
    set forward-server "server-commercial"
    set url-pattern "com"
  next
  edit "ca"
    set forward-server "server-canada"
    set url-pattern "ca"
  next
  edit "www.google.ca"
    set cache-exemption enable
    set url-pattern "www.google.ca"
  next
end
```

Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. You can add URLs and numeric IP addresses to the web cache exempt list.

You can also add URLs to the web cache exempt list by going to **Network > Explicit Proxy**, going to the **URL Match List**

URL Match List

+ Create New Edit Delete

Name	URL Pattern	Cache Exemption	Forward Server	Status	Comments
No matching entries found					

and selecting **Create New**. Add a URL pattern to be exempt and select **Exempt from Cache**.

New URL Match Entry

Name

Comments 0/255

URL Pattern

Forward to Server ☐

Exempt from Cache ☒

Enable this URL ☒

You can also add URLs and addresses to be exempt from caching using the CLI. Enter the following command to add `www.example.com` to the web cache exempt list:

```
config web-proxy url-match
  set cache-exemption enable
  set url-pattern www.example.com
end
```

Exempting specific files from caching

You can exempt files from being cached, so long as you specify its full URL. Enter the following command to add the URL, with the file extension (in this example, `.exe`), to the web cache exempt list:

```
config web-proxy url-match
  edit "exe"
    set url-pattern "iavs9x.u.avast.com/custom/iavs9x/20160613t1237z/avast_free_
      antivirus_setup_online.exe"
    set cache-exemption enable
  next
end
```

You cannot use wildcards to exempt file extensions in general from caching.

Monitoring Web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to **Monitor > Cache Monitor**.

Web cache monitor

Example Web caching of HTTP and HTTPS Internet content for users on an internal network

This example describes how to configure web caching of HTTP and HTTPS for users on a private network connecting to the Internet.

Network topology and assumptions

This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet. All of the users on the private network access the Internet through a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching for HTTP and HTTPS traffic is added to this security policy.

Since users on the private network have unrestricted access to the Internet and can be accessing many web servers the `webcache-https` is set to `any` and users may see error messages on their web browsers when accessing HTTPS content.

The GUI is less versatile than the CLI so the example instructions for the GUI give settings for one port for each protocol, while the CLI example shows how to use multiple ports.

The example also describes how to configure the security policy to cache HTTP traffic on port 80 and 8080 in the CLI, by adding a proxy options profile that looks for HTTP traffic on TCP ports 80 and 8080. The example also describes how to configure the security policy to cache HTTPS traffic on port 443 and 8443 using the same proxy options profile.

Example web caching topology

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Add HTTP web caching to the security policy that all users on the private network use to connect to the Internet.
2. Add HTTPS web caching.

3. Add a protocol options profile to look for HTTP traffic on ports 80 and 8080 and HTTPS traffic on ports 443 and 8443 and add this protocol options profile to the security policy.

If you perform any additional actions between procedures, your configuration may have different results.

Configuration Steps - web-based manager

Use the following steps to configure the example configuration from the FortiGate web-based manager.

To add HTTP web caching to a security policy

1. Go to **Policy & Objects > IPv4 Policy** and add a security policy that allows all users on the internal network to access the Internet.

Incoming Interface	Internal
Outgoing Interface	wan1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

2. Toggle **NAT** to enabled, and select **Use Outgoing Interface Address**.
3. Turn on **Web cache**.
4. Select **OK**.

To add HTTPS web caching

1. From the CLI enter the following command to add HTTPS web caching to the policy.

Assume the index number of the policy is 5.

```
config firewall policy
edit 5
set webcache-https any
end
```

To cache HTTP traffic on port 80 and HTTPS on 8443

1. Go to **Network > Explicit Proxy** and edit the Explicit Proxy options profile.
2. Under **Explicit Web Proxy** ,
 - For the **HTTP port**, enter 80.
 - For **HTTPS port**, select **Specify** and enter 8443 in the field.
3. Click on **Apply**.

You need to use the CLI to add the protocol options profile unless you also add a security profile that uses proxy-based inspection.

Configuration Steps - CLI

Use the following steps to configure the example configuration from the FortiGate CLI.

To add HTTP and HTTPS web caching to a security policy

1. Enter the following command to add a security policy that allows all users on the internal network to access the Internet and that includes web caching of HTTP and HTTPS traffic.

```
config firewall policy
edit 0
set srcintf internal
set srcaddr all
set dstintf wan1
set dstintf all
set schedule always
set service ALL
set action accept
set nat enable
set webcache enable
set webcache-https any
end
```

To cache HTTP traffic on port 80 and 8080 and HTTPS traffic on ports 443 and 8443

1. Enter the following command to edit the **default** proxy options profile to configure it to look for HTTP traffic on ports 80 and 8080:

```
config firewall profile-protocol-options
edit default
config http
set status enable
set ports 80 8080
end
```

2. Enter the following command to edit the **certificate-inspection** SSL SSH options profile to configure it to look for HTTPS traffic on ports 443 and 8443:

```
config firewall ssl-ssh-profile
edit certificate-inspection
config https
set status certificate-inspection
set ports 443 8443
end
```

3. Enter the following command to add the **default** proxy options profile and the **certificate-inspection** SSL SSH profile to the firewall policy.

```
config firewall policy
edit 5
set utm-status enable
set profile-protocol-options default
set ssl-ssh-profile certificate-inspection
```

end

Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP

This section describes configuring SSL offloading for a reverse proxy web caching configuration using a static one-to-one firewall virtual IP (VIP). While the static one-to-one configuration described in this example is valid, its also common to change the destination port of the unencrypted HTTPS traffic to a commonly used HTTP port such as 8080 using a port forwarding virtual IP.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP and HTTPS to browse to a web server that is behind a FortiGate unit. A policy added to the FortiGate unit forwards the HTTP traffic to the web server. The policy also offloads HTTPS decryption and encryption from the web server so the web server only sees HTTP traffic.

The FortiGate unit also caches HTTP and HTTPS pages from the web server so when users access cached pages the web server does not see the traffic. Replies to HTTPS sessions are encrypted by the FortiGate unit before returning to the clients.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is "cache aware" to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for clients on the Internet. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

This example assumes that all HTTP traffic uses port 80 and all HTTPS traffic uses port 443.

The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 443. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming HTTP and HTTPS sessions is translated to the IP address of the web server using a static one-to-one virtual IP that performs destination address translation (DNAT) for the HTTP packets. The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port number.

When the SSL server on the FortiGate unit decrypts the HTTPS packets their destination port is changed to port 80.

Reverse proxy web caching and SSL offloading for an Internet web server using static one-to-one virtual IPs

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the FortiGate unit as a reverse proxy web cache server.
2. Configure the FortiGate unit for SSL offloading of HTTPS traffic.
3. Add an SSL server to offload SSL encryption and decryption for the web server.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server

1. Go to **Policy & Objects > Virtual IPs** and select **Create New** to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

VIP Type	IPv4
Name	Reverse_proxy_VIP
Interface	port2
Type	Static NAT
Optional Filters	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2. Select **OK**.
3. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	Reverse_proxy_VIP

Schedule	always
Service	HTTP HTTPS
Action	ACCEPT

4. Turn on **Web Cache**.
5. Select **OK**.
6. From the CLI enter the following command to add HTTPS web caching to the security policy

Assume the index number of the policy is 5.

```
config firewall policy
edit 5
set webcache-https ssl-server
end
```

To configure the FortiGate unit to offload SSL encryption and cache HTTPS content

1. Go to **System > Certificates** and select **Import** to import the web server's CA.

For **Type**, select **Local Certificate**. Select the **Browse** button to locate the file (example file name: Rev_Proxy_Cert_1.crt).

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

2. Select **OK** to import the certificate.
3. From the CLI, enter the following command to add the SSL server and to add the server's certificate to the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
edit rev_proxy_server
set ip 172.10.20.30
set port 443
set ssl-mode half
set ssl-cert Rev_Proxy_Cert_1
end
```

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server

1. Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
edit Reverse_proxy_VIP
set extintf port2
set type static-nat
set extip 192.168.10.1
set mappedip 172.10.20.30
```

end

2. Enter the following command to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet. Enable web caching and HTTPS web caching.

Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
edit 0
set srcintf port2
set srcaddr all
set dstintf port1
set dstaddr Reverse_proxy_VIP
set schedule always
set service HTTP HTTPS
set action accept
set webcache enable
set webcache-https ssl-server
end
```

To add an SSL server to offload SSL encryption and decryption for the web server

1. Place a copy of the web server's CA (file name Rev_Proxy_Cert_1.crt) in the root folder of a TFTP server.
2. Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt 10.31.101.30
```

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

3. From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config firewall ssl-server
edit rev_proxy_server
set ip 172.10.20.30
set port 443
set ssl-mode half
set ssl-cert Rev_Proxy_Cert_1
end
```

4. Configure other `ssl-server` settings that you may require for your configuration.

Using a FortiCache as a cache service

Some FortiGate devices don't have sufficient memory or disk space to run a cache service. This feature allows a FortiGate to connect to a FortiCache that has a higher cache capability than most FortiGates.

Syntax:

```
config wanopt remote-storage
set status {enable|disable}
set local-cache-id <name ID for connection>
set remote-cache-id <ID of the remote device>
set remote-cache-ip <IP address of the remote device>
```

end

Option	Description
status	Enable or disable whether the FortiGate uses a remote caching device as web-cache storage. If disabled, uses local disk(s) as web storage.
local-cache-id	ID that this device uses to connect to the remote caching device
remote-cache-id	ID of the remote caching device that this FortiGate connects to
remote-cache-ip	IP address of the remote caching device that this FortiGate connects to.

WCCP Concepts

The Web Cache Communication Protocol (WCCP) can be used to provide web caching with load balancing and fault tolerance. In a WCCP configuration, a WCCP server receives HTTP requests from user's web browsers and redirects the requests to one or more WCCP clients. The clients either return cached content or request new content from the destination web servers before caching it and returning it to the server which in turn returns the content to the original requestor. If a WCCP configuration includes multiple WCCP clients, the WCCP server load balances traffic among the clients and can detect when a client fails and failover sessions to still operating clients. WCCP is described by the [Web Cache Communication Protocol Internet draft](#).

The sessions that are cached by WCCP depend on the configuration of the WCCP clients. If the client is a FortiGate unit, you can configure the port numbers and protocol number of the sessions to be cached. For example, to cache HTTPS traffic on port 443 the WCCP client port must be set to 443 and protocol must be set to 6. If the WCCP client should also cache HTTPS traffic on port 993 the client ports option should include both port 443 and 993.

On a FortiGate unit, WCCP sessions are accepted by a security policy before being cached. If the security policy that accepts sessions that do not match the port and protocol settings in the WCCP clients the traffic is dropped.

WCCP is configured per-VDOM. A single VDOM can operate as a WCCP server or client (not both at the same time). FortiGate units are compatible with third-party WCCP clients and servers. If a FortiGate unit is operating as an Internet firewall for a private network, you can configure it to cache and serve some or all of the web traffic on the private network using WCCP by adding one or more WCCP clients, configuring WCCP server settings on the FortiGate unit and adding WCCP security policies that accept HTTP session from the private network.

FortiGate units support WCCPv1 and WCCPv2. A FortiGate unit in NAT or transparent mode can operate as a WCCP server. To operate as a WCCP client a FortiGate unit must be in NAT mode. FortiGate units communicate between WCCP servers and clients over UDP port 2048. This communication can be encapsulated in a GRE tunnel or just use layer 2 forwarding.

A WCCP server can also be called a WCCP router. A WCCP client can also be called a WCCP cache engine.

WCCP Configuration

WCCP configuration overview

To configure WCCP you must create a service group that includes WCCP servers and clients. WCCP servers intercept sessions to be cached (for example, sessions from users browsing the web from a private network). To intercept sessions to be cached the WCCP server must include a security policy that accepts sessions to be cached and WCCP must be enabled in this security policy.

The server must have an interface configured for WCCP communication with WCCP clients. That interface sends and receives encapsulated GRE traffic to and from WCCP clients. The server must also include a WCCP service group that includes a service ID and the addresses of the WCCP clients as well as other WCCP configuration options.

To use a FortiGate unit as a WCCP client, the FortiGate unit must be set to be a WCCP client (or cache engine). You must also configure an interface on the client for WCCP communication. The client sends and receives encapsulated GRE traffic to and from the WCCP server using this interface.

The client must also include a WCCP service group with a service ID that matches a service ID on the server. The client service group also includes the IP address of the servers in the service group and specifies the port numbers and protocol number of the sessions that will be cached on the client.

When the client receives sessions from the server on its WCCP interface, it either returns cached content over the WCCP interface or connects to the destination web servers using the appropriate interface depending on the client routing configuration. Content received from web servers is then cached by the client and returned to the WCCP server over the WCCP link. The server then returns the received content to the initial requesting user web browser.

Finally you may also need to configure routing on the server and client FortiGate units and additional security policies may have to be added to the server to accept sessions not cached by WCCP.

WCCP service groups, service numbers, service IDs and well known services

A FortiGate unit configured as a WCCP server or client can include multiple server or client configurations. Each of these configurations is called a WCCP service group. A service group consists of one or more WCCP servers (or routers) and one or more WCCP clients working together to cache a specific type of traffic. The service group configuration includes information about the type of traffic to be cached, the addresses of the WCCP clients and servers and other information about the service.

A service group is identified with a numeric WCCP service ID (or service number) in the range 0 to 255. All of the servers and clients in the same WCCP service group must have service group configurations with the same WCCP service ID.

The value of the service ID provides some information about the type of traffic to be cached by the service group. Service IDs in the range 0 to 50 are reserved for well known services. A well known service is any service that is defined by the WCCP standard as being well known. Since the service is well known, just the service ID is required to identify the traffic to be cached.

Even though the well known service ID range is 0 to 50, at this time only one well known service has been defined. Its service ID 0, which is used for caching HTTP (web) traffic.

So to configure WCCP to cache HTTP sessions you can add a service group to the WCCP router and WCCP clients with a service ID of 0. No other information about the type of traffic to cache needs to be added to the service group.

Since service IDs 1 to 50 are reserved for well know services and since these services are not defined yet, you should not add service groups with IDs in the range 1 to 50.

FortiOS does allow you to add service groups with IDs between 1 and 50. Since these service groups have not been assigned well known services, however, they will not cache any sessions. Service groups with IDs 51 to 255 allow you to set the port numbers and protocol number of the traffic to be cached. So you can use service groups with IDs 51 to 255 to cache different kinds of traffic based on port numbers and protocol number of the traffic. Service groups 1 to 50; however, do not allow you to set port numbers or protocol numbers so cannot be used to cache any traffic.

To cache traffic other than HTTP traffic you must add service groups with IDs in the range 51 to 255. These service group configurations must include the port numbers and protocol number of the traffic to be cached. It is the port and protocol number configuration in the service group that determines what traffic will be cached by WCCP.

Example WCCP server and client configuration for caching HTTP sessions (service ID = 0)

Enter the following command to add a WCCP service group to a WCCP server that caches HTTP sessions. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service

ID of this service group is 0.

```
config system wccp
  edit 0
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures the client to cache HTTP sessions. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group is 0.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 0
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
  end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

Example WCCP server and client configuration for caching HTTPS sessions

Enter the following command to add a service group to a WCCP server that caches HTTPS content on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 80.

```
config system settings
    set wccp-cache-engine enable
end

config system wccp
    edit 80
        set router-id 10.31.101.100
        set server-list 10.31.101.0 255.255.255.0
        set ports 443
        set protocol 6
    end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTPS sessions on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 80 to match the service ID added to the server.

```
config system settings
    set wccp-cache-engine enable
end

config system wccp
    edit 80
        set cache-id 10.31.101.1
        set router-list 10.31.101.100
        set ports 443
        set protocol 6
    end
```

Example WCCP server and client configuration for caching HTTP and HTTPS sessions

You could do this by configuring two WCCP service groups as described in the previous examples. Or you could use the following commands to configure one service group for both types of traffic. The example also caches HTTP sessions on port 8080.

Enter the following command to add a service group to a WCCP server that caches HTTP sessions on ports 80 and 8080 and HTTPS sessions on port 443. Both of these protocols use protocol number 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 90.

```
config system wccp
    edit 90
        set router-id 10.31.101.100
        set server-list 10.31.101.0 255.255.255.0
        set ports 443 80 8080
        set protocol 6
    end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTP sessions on port 80 and 8080 and HTTPS sessions on port 443. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 90 to match the service ID added to the server.

```
config system settings
    set wccp-cache-engine enable
end
config system wccp
    edit 90
        set cache-id 10.31.101.1
        set router-list 10.31.101.100
        set ports 443 80 8080
        set protocol 6
    end
```

Other WCCP service group options

In addition to using WCCP service groups to define the types of traffic to be cached by WCCP the following options are available for servers and clients.

Server configuration options

The server configuration must include the `router-id`, which is the WCCP server IP address. This is the IP address of the interface that the server uses to communicate with WCCP clients.

The `group-address` is used for multicast WCCP configurations to specify the multicast addresses of the clients.

The `server-list` defines the IP addresses of the WCCP clients that the server can connect to. Often the server list can be the address of the subnet that contains the WCCP clients.

The `authentication` option enables or disables authentication for the WCCP service group. Authentication must be enabled on all servers and clients in a service group and members of the group must have the same password.

The `forward-method` option specifies the protocol used for communication between the server and clients. The default forwarding method is GRE encapsulation. If required by your network you can also select to use unencapsulated layer-2 packets instead of GRE or select any to allow both. The `return-method` allows you to specify the communication method from the client to the server. Both GRE and layer-2 are supported.

The `assignment-method` determines how the server load balances sessions to the clients if there are multiple clients. Load balancing can be done using hashing or masking.

Client configuration options

The client configuration includes the `cache-id` which is the IP address of the FortiGate interface of the client that communicates with WCCP server. The `router-list` option is the list of IP addresses of the WCCP servers in the WCCP service group.

The `ports` option lists the port numbers of the sessions to be cached by the client and the `protocol` sets the protocol number of the sessions to be cached. For TCP sessions the protocol is 6.

The `service-type` option can be auto, dynamic or standard. Usually you would not change this setting.

The client configuration also includes options to influence load balancing including the `primary-hash`, `priority`, `assignment-weight` and `assignment-bucket-format`.

Example caching HTTP sessions on port 80 using WCCP

In this example configuration (shown below), a FortiGate unit with host name WCCP_srv is operating as an Internet firewall for a private network is also configured as a WCCP server. The port1 interface of WCCP_srv is connected to the Internet and the port2 interface is connected to the internal network.

All HTTP traffic on port 80 that is received at the port2 interface of WCCP_srv is accepted by a port2 to port1 security policy with WCCP enabled. All other traffic received at the port2 interface is allowed to connect to the Internet by adding a general port2 to port1 security policy below the HTTP on port 80 security policy.

A WCCP service group is added to WCCP_srv with a service ID of 0 for caching HTTP traffic on port 80. The port5 interface of WCCP_srv is configured for WCCP communication.

A second FortiGate unit with host name WCCP_client is operating as a WCCP client. The port1 interface of WCCP_client is connected to port5 of WCCP_srv and is configured for WCCP communication.

WCCP_client is configured to cache HTTP traffic because it also has a WCCP service group with a service ID of 0.

WCCP_client connects to the Internet through WCCP_srv. To allow this, a port5 to port1 security policy is added to WCCP_srv.

FortiGate WCCP server and client configuration

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and is configured for WCCP:

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
  
```

```

        set action accept
        set schedule always
        set service HTTP
        set wccp enable
        set nat enable
    end

```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```

config firewall policy
    edit 0
        set srtintf port2
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set nat enable
    end

```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.
4. Enable WCCP on the port5 interface.

```

config system interface
    edit port5
        set wccp enable
    end

```

5. Add a WCCP service group with service ID 0.

```

config system wccp
    edit 0
        set router-id 10.51.101.100
        set server-list 10.51.101.0 255.255.255.0
    end

```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```

config firewall address
    edit WCCP_client_addr
        set subnet 10.51.101.10
    end
config firewall policy
    edit 0
        set srtintf port5
        set dstintf port1
        set srcaddr WCCP_client_addr
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set nat enable
    end

```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
    set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
    edit port1
        set wccp enable
    end
```

3. Add a WCCP service group with service ID 0.

```
config system wccp
    edit 0
        set cache-id 10.51.101.10
        set router-list 10.51.101.100
    end
```

Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP

This example configuration is the same as that described in [Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP on page 1182](#) except that WCCP now also cached HTTPS traffic on port 443. To cache HTTP and HTTPS traffic the WCCP service group must have a service ID in the range 51 to 255 and you must specify port 80 and 443 and protocol 6 in the service group configuration of the WCCP client.

Also the security policy on the WCCP_srv that accepts sessions from the internal network to be cached must accept HTTP and HTTPS sessions.

FortiGate WCCP server and client configuration

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and HTTPS traffic on port 443 and is configured for WCCP:

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP HTTPS
    set wccp enable
    set nat enable
  end

```

2. Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```

config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL

    set nat enable
  end

```

3. Move this policy below the WCCP policy in the port2 to port1 policy list.
4. Enable WCCP on the port5 interface.

```
config system interface
edit port5
set wccp enable
end
```

5. Add a WCCP service group with service ID 90 (can be any number between 51 and 255).

```
config system wccp
edit 90
set router-id 10.51.101.100
set server-list 10.51.101.0 255.255.255.0
end
```

6. Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
edit WCCP_client_addr
set subnet 10.51.101.10
end
config firewall policy
edit 0
set srtintf port5
set dstintf port1
set srcaddr WCCP_client_addr
set dstaddr all
set action accept
set schedule always
set service ALL
set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named `w.<vdom_name>` is added to the FortiGate configuration (for example `w.root`). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2. Enable WCCP on the port1 interface.

```
config system interface
edit port1
set wccp enable
```

```
end
```

3. Add a WCCP service group with service ID 90. This service group also specifies to cache sessions on ports 80 and 443 (for HTTP and HTTPS) and protocol number 6.

```
config system wccp
edit 90
set cache-id 10.51.101.10
set router-list 10.51.101.100
ports 80 443
set protocol 6
end
```

WCCP packet flow

The following packet flow sequence assumes you have configured a FortiGate unit to be a WCCP server and one or more FortiGate units to be WCCP clients.

1. A user's web browser sends a request for web content.
2. The FortiGate unit configured as a WCCP server includes a security policy that intercepts the request and forwards it to a WCCP client.

The security policy can apply UTM features to traffic accepted by the policy.

3. The WCCP client receives the WCCP session.
4. The client either returns requested content to the WCCP server if it is already cached, or connects to the destination web server, receives and caches the content and then returns it to the WCCP server.
5. The WCCP server returns the requested content to the user's web browser.
6. The WCCP router returns the request to the client web browser.

The client web browser is not aware that all this is taking place and does not have to be configured to use a web proxy.

Configuring the forward and return methods and adding authentication

The WCCP forwarding method determines how intercepted traffic is transmitted from the WCCP router to the WCCP cache engine. There are two different forwarding methods:

- GRE forwarding (the default) encapsulates the intercepted packet in an IP GRE header with a source IP address of the WCCP router and a destination IP address of the target WCCP cache engine. The result is a tunnel that allows the WCCP router to be multiple hops away from the WCCP cache server.
- L2 forwarding rewrites the destination MAC address of the intercepted packet to match the MAC address of the target WCCP cache engine. L2 forwarding requires that the WCCP router is Layer 2 adjacent to the WCCP client.

You can use the following command on a FortiGate unit configured as a WCCP router to change the forward and return methods to L2:

```
config system wccp
edit 1
set forward-method L2
set return-method L2
end
```

You can also set the forward and return methods to any in order to match the cache server configuration.

By default the WCCP communication between the router and cache servers is unencrypted. If you are concerned about attackers sniffing the information in the WCCP stream you can use the following command to enable hash-based authentication of the WCCP traffic. You must enable authentication on the router and the cache engines and all must have the same password.

```
config system wccp
  edit 1
    set authentication enable
    set password <password>
  end
```

WCCP Messages

When the WCCP service is active on a web cache server it periodically sends a WCCP HERE I AM broadcast or unicast message to the FortiGate unit operating as a WCCP router. This message contains the following information:

- Web cache identity (the IP address of the web cache server).
- Service info (the service group to join).

If the information received in the previous message matches what is expected, the FortiGate unit replies with a WCCP I SEE YOU message that contains the following details:

- Router identity (the FortiGate unit's IP address).
- Sent to IP (the web cache IP addresses to which the packets are addressed)

When both ends receive these two messages the connection is established, the service group is formed and the designated web cache is elected.

Troubleshooting WCCP

Two types of debug commands are available for debugging or troubleshooting a WCCP connection between a FortiGate unit operating as a WCCP router and its WCCP cache engines.

Real time debugging

The following commands can capture live WCCP messages:

```
diag debug en
diag debug application wccpd <debug level>
```

Application debugging

The following commands display information about WCCP operations:

```
get test wccpd <integer>
diag test application wccpd <integer>
```

Where <integer> is a value between 1 and 6:

1. Display WCCP stats
2. Display WCCP config
3. Display WCCP cache servers
4. Display WCCP services
5. Display WCCP assignment
6. Display WCCP cache status

Enter the following command to view debugging output:

```
diag test application wccpd 3
```

Sample output from a successful WCCP connection:

```
service-0 in vdom-root: num=1, usable=1
cache server ID:
len=44, addr=172.16.78.8, weight=4135, status=0
rcv_id=6547, usable=1, fm=1, nq=0, dev=3(k3),
to=192.168.11.55
ch_no=0, num_router=1:
192.168.11.55
```

Sample output from the same command from an unsuccessful WCCP connection (because of a service group password mismatch):

```
service-0 in vdom-root: num=0, usable=0
diag debug application wccpd -1
Sample output:
wccp_on_recv()-98: vdom-root recv: num=160, dev=3(3),
172.16.78.8->192.168.11.55
wccp2_receive_pkt()-1124: len=160, type=10, ver=0200,
length=152
wccp2_receive_pkt()-1150: found component:t=0, len=20
wccp2_receive_pkt()-1150: found component:t=1, len=24
wccp2_receive_pkt()-1150: found component:t=3, len=44
wccp2_receive_pkt()-1150: found component:t=5, len=20
wccp2_receive_pkt()-1150: found component:t=8, len=24
wccp2_check_security_info()-326: MD5 check failed
```

Web Proxy Concepts

These are concepts that apply to both Transparent and Explicit Proxy.

Proxy Policy

Information on Proxy policy options can be found at [Proxy Option Components on page 964](#)

Configuration information can be found at [Web Proxy Configuration on page 1194](#)

Proxy Authentication

Beginning in FortiOS 5.6, authentication is separated from authorization for user based policy. You can add authentication to proxy policies to control access to the policy and to identify users and apply different UTM features to different users. The described authentication methodology works with **Explicit Web Proxy** and **Transparent Proxy**.

Authentication of web proxy sessions uses HTTP basic and digest authentication as described in [RFC 2617 \(HTTP Authentication: Basic and Digest Access Authentication\)](#) and prompts the user for credentials from the browser allowing individual users to be identified by their web browser instead of IP address. HTTP authentication allows the FortiGate unit to distinguish between multiple users accessing services from a shared IP address.

The methodology of adding authentication has changed from FortiOS version 5.4 and previous version. Split-policy has been obsoleted and instead of identity-based-policy, authentication is managed by

authentication scheme, setting and rule settings. These authentication settings are no longer configured with the individual policies. Authentication is set up in the contexts of:

```
config authentication scheme
config authentication setting
config authentication rule
```

The Authentication rule table defines how to identify user-ID. It uses the match factors:

- Protocol
- Source Address

For one address and protocol, there is only one authentication rule. It is possible to configure multiple authentication methods for on one address. The client browser will chose one authentication method from the authentication methods list, but you can not control which authentication method will be chosen by the browser.

Matching

If a rule is matched, the authentication methods defined in the rule will be used to authenticate a user. The procedure works as the following:

1. If it is IP-based, look up active user list to see a user existed from the source IP. If found, return the user ID.
2. If no method is set, an anonymous user is created to associate to the source-IP. Return the anonymous user. It is another way to bypass user authentication for some source IPs.
3. Use authentication methods to authenticate the user.
 - If no active method is defined, a failure will result to return an anonymous user.
 - Otherwise, a valid or guest user has to be identified to move on.
 - Return the identified user ID.

Once a user is returned, the policy match resumes until a policy is matched or default policy will be used.

Processing policies for Authentication

Authentication rules are checked once a User-ID is needed in order to resolve a match to a policy

Use the following scenario as an example of the process.

There are 3 policies:

- `policy1` does not have an associated user group
- `policy2` has an associated user group
- `policy3` does not have an associated user group

Step 1

If the traffic, based on protocol and source address matches `policy 1`, no user authentication is needed. The traffic is processed by `policy1`.

Step 2

If the traffic does not match `policy 1`, and any factor of `policy 2` is not matched, continue to next policy.

If all the factors except the user-group of `policy 2` are matched the authentication rule table is checked to get user-ID in the process in based on the procedure described earlier in Matching.

Step 3

When a user-ID is returned, whether it is a valid user or anonymous user, it is checked to see if the user is authorized by the user group associated with `policy2`. If yes, it is a match of `policy2`, and the traffic is processed by `policy2`. If not move on the next policy.

Step 4

For the purposes of the scenario, it will be assumed that the traffic either matches `policy3` or that `policy3` is the final policy that denies everything.

CLI Syntax

Removals:

- "split-policy" from firewall explicit-proxy-policy.

The previous method to set up a split policy was:

```
config firewall explicit-proxy-policy
  edit 1
    set proxy web
    set identity-based enable
    set groups <User group>
    config identity-based-policy
      edit 1
        set schedule "always"
        set utm-status enable
        set users "guest"
        set profile-protocol-options "default"
      next
    end
  next
end
```

- "auth relative" from firewall explicit-proxy-policy

The following attributes have been removed from firewall explicit-proxy-policy:

- identity-based
- ip-based
- active-auth-method
- sso-auth-method
- require-tfa

Moves:

users and groups from

```
firewall explicit-proxy-policy identity-based-policy
to

config firewall proxy-policy
  edit 1
    set groups <Group name>
    set users <User name>
```

end

Additions:

authentication scheme

```
config authentication scheme
  edit <name>
    set method [ntlm|basic|digest|form|negotiate|fsso|rsso|none]
```

- `ntlm` - NTLM authentication.
- `basic` - Basic HTTP authentication.
- `digest` - Digest HTTP authentication.
- `form` - Form-based HTTP authentication.
- `negotiate` - Negotiate authentication.
- `fsso` - FSSO authentication.
- `rsso` - RADIUS Single Sign-On authentication.
- `none` - No authentication.

authentication setting

```
config authentication setting
  set active-auth-scheme <string>
  set sso-auth-scheme <string>
  set captive-portal <string>
  set captive-portal-port <integer value from 1 to 65535>
```

- `active-auth-scheme` - Active authentication method.
- `sso-auth-scheme` - SSO authentication method.
- `captive-portal` - Captive portal host name.
- `captive-portal-port` - Captive portal port number.

authentication rule

```
config authentication rule
  edit <name of rule>
    set status [enable|disable]
    set protocol [http|ftp|socks]
    set srcaddr <name of address object>
    set srcaddr6 <name of address object>
    set ip-based [enable|disable]
    set active-auth-method <string>
    set sso-auth-method <string>
    set web-auth-cookie [enable|disable]
    set transaction-based [enable|disable]
    set comments
```

- `status` - Enable/disable auth rule status.
- `protocol` - set protocols to be matched
- `srcaddr` / `srcaddr6` - Source address name. [`srcaddr` or `srcaddr6`(web proxy only) must be set].
- `ip-based` - Enable/disable IP-based authentication.

- `active-auth-method` - Active authentication method.
- `sso-auth-method` - SSO authentication method (require `ip-based` enabled)
- `web-auth-cookie` - Enable/disable Web authentication cookie.
- `transaction-based` - Enable/disable transaction based authentication.
- `comments` - Comment.

Configuring Authentication in Transparent Proxy

You can enable transparent web-proxy feature to support authentication. Follow these steps

1. Configure a firewall policy
2. Enable a UTM profile in the firewall policy. Whenever there is a UTM item enabled, the feature enables the `profile-protocol-options`.
3. Go to the **Proxy Options** profile.
 - In the GUI this is **Security Profiles > Proxy Options**.
 - In the CLI it is `config firewall profile-protocol-options`.

Edit the profile used by the policy.

4. Enable HTTP in the profile.
In the GUI toggle on **HTTP** under **Protocol Port Mapping**

In the CLI, the command sequence is:

```
config firewall profile-protocol-options
edit <profile id>
config http
set status enable
end
```

Fill out any other appropriate values.

5. Configure the proxy-policy, and set the value `transparent-web` for proxy option, others configuration are same as the explicit-web proxy

In the GUI, go to **Policy & Objects > Proxy Policy**. In the **Proxy Type** field choose **Transparent Web**.

In the CLI, the command sequence is:

```
config firewall proxy-policy
edit <profile id>
set proxy transparent-web
end
```

Fill out any other appropriate values.

6. Setup the authentication rule and scheme

With this configuration, if a HTTP request passes through FortiGate without explicit web proxy being applied, the traffic will be redirected to WAD daemon after it matches the proxy with HTTP-policy enabled, then WAD will do the proxy-policy matching, and all of the proxy authentication method can be used for the request.

Proxy Addresses

Information on Proxy addresses can be found at [Proxy Addresses on page 1080](#)

Proxy Address group

In the same way that IPv4 and IPv6 addresses can only be grouped together, Proxy addresses can only be grouped with other Proxy addresses. Unlike the other address groups, the Proxy address groups are further divided into source address groups and destination address groups. To see the configuration steps go to [Proxy Address Groups on page 1082](#)

Web Proxy firewall services and service groups

Configure web proxy services by selecting **Explicit Proxy** when configuring a service. Web proxy services can be selected in a explicit web proxy policy when adding one from the CLI. If you add a policy from the web-based manager the service is set to the **webproxy** service. The webproxy service should be used in most cases, it matches with any traffic with any port number. However, if you have special requirements, such as using a custom protocol type or a reduced port range or need to add an IP/FQDN to an proxy service you can create custom explicit web proxy services.

Web proxy services are similar to standard firewall services. You can configure web proxy services to define one or more protocols and port numbers that are associated with each web proxy service. Web proxy services can also be grouped into web proxy service groups.

One way in which web proxy services differ from firewall services is the protocol type you can select. The following protocol types are available:

- ALL
- CONNECT
- FTP
- HTTP
- SOCKS-TCP
- SOCKS-UDP

To add a web proxy service go to **Policy & Objects > Services** and select **Create New**. Set **Service Type** to **Explicit Proxy** and configure the service as required.

To add a web proxy service from the CLI enter:

```
config firewall service custom
  edit my-socks-service
    set explicit-proxy enable
    set category Web Proxy
    set protocol SOCKS-TCP
    set tcp-portrange 3450-3490
  end
```

To add a web proxy service group go to **Policy & Objects > Services** and select **Create New > Service Group**. Set **Type** to **Explicit Proxy** and add web proxy services to the group as required.

To add a web proxy service group from the CLI enter:

```
config firewall service group
  edit web-group
    set explicit-proxy enable
    set member webproxy my-socks-service
  end
```

Learn client IP

If there is another NATing device between the FortiGate and the Client (browser), this feature can be used to identify the real client in spite of the address translation. Knowing the actual client is imperative in cases where authorization is taking place.

The settings for the feature are in the CLI in the context of

```
config web-proxy global
```

Once here, enable the feature with the command:

```
set learn-client-ip enable
```

Once the feature is enabled, the other settings become available.

```
learn-client-ip-from-header
```

This command has the following options:

true-client-ip	Support HTTP header True-Client-IP.
x-real-ip	Support HTTP header X-Real-IP.
x-forwarded-for	Support HTTP header X-Forwarded-For.

```
learn-client-ip-srcaddr/learn-client-ip-srcaddr6
```

The options for this setting are selected from the list of IPv4 address or IPv6 address objects.

Example

Below is a config example where the real client ip address will be used to match policy or fsso authentication after the learn-client-ip feature enabled.

The value of `learn-client-ip-from-header` option can be set to `true-client-ip`, `x-real-ip` or `x-forwarded-for`, but in this case it has been set to `x-forward-for`.

```
config web-proxy global
  set proxy-fqdn "default.fqdn"
  set webproxy-profile "default"
  set learn-client-ip enable
  set learn-client-ip-from-header x-forwarded-for
  set learn-client-ip-srcaddr "all"
end

config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "mgmt1"
    set srcaddr "all"
    set dstaddr "all"
    set service "w"
    set action accept
```

```
set schedule "always"
set groups "fssol"
set utm-status enable
set av-profile "default"
set dlp-sensor "default"
set profile-protocol-options "default"
set ssl-ssh-profile "deep-inspection"
end

config authentication rule
edit "rule1"
set srcaddr "all"
set sso-auth-method "scheme1"
end

config authentication scheme
edit "scheme1"
set method fsso
end
```

Web Proxy Configuration

General web proxy configuration steps

You can use the following general steps to configure the explicit web proxy.

To enable the explicit web proxy - web-based manager:

1. Go to **Network > Explicit Proxy** and enable **Explicit Web Proxy**. From here you can optionally change the HTTP port that the proxy listens on (the default is 8080) and optionally specify different ports for HTTPS, FTP, PAC, and other options.
2. Optionally enable **IPv6 Explicit Proxy** to turn on the explicit web proxy for IPv6 traffic.

If you enable both the IPv4 and the IPv6 explicit web proxy you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

3. Select **Apply**.
4. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface. Under the **Miscellaneous** heading select **Enable Explicit Web Proxy**.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address that matches the source address of packets to be accepted by the explicit proxy.

Category	Address
Name	Internal_subnet
Type	IP Range
Subnet / IP Range	10.31.101.1 - 10.31.101.255
Interface	any*

*The **Interface** must be set to **Any**.

You can also set the **Type** to **URL Pattern (Explicit Proxy)** to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

Category	Address
Name	Fortinet-web-sites
Type	URL Pattern (Explicit Proxy)
URL Pattern	fortinet.com
Interface	any

- Go to **Policy & Objects > Proxy Policy** and select **Create New**. Configure the policy as required to accept the traffic that you want to be allowed to use the explicit web proxy.
- Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
- The **Source** of the policy must match the client's source IP addresses. The interface of this firewall address must be set to **any**.
- The **Destination** field should match the addresses of web sites that clients are connecting to. Usually the destination address would be **all** if proxying Internet web browsing. You could also specify a URL firewall address to limit the policy to allowing access to this URL.
- Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
- If **Default Firewall Policy Action** is set to **Deny** (under **Network > Explicit Proxy**), traffic sent to the explicit web proxy that is not accepted by a web-proxy policy is dropped. If **Default Firewall Policy Action** is set to **Allow** then all web-proxy sessions that don't match with a security policy are allowed.

For example, the following security policy allows users on an internal network to access fortinet.com websites through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	Web
Source Address	Internal_subnet

Outgoing Interface	wan1
Destination Address	Fortinet-web-sites
Schedule	always
Action	ACCEPT

The explicit web-proxy accepts VIP addresses for destination addresses. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

12. Set the **Disclaimer Options**

You can configure a disclaimer for each Authentication Rule by enabling one of the options here. The choices are:

Disable	No disclaimer (default setting)
By Domain	The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
By Policy	The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
By User	The disclaimer will be displayed when a new user logs on.

If you chose a disclaimer option other than **Disable**, you will have the option to enable **Customize Messages**. If enabled, select the **Edit Disclaimer Message** button to customize the message to your needs. This can be done as text or as HTML. The default HTML version is there if you just want to make minor changes.

13. Enable **Security Profiles** as required. Once the profile type is toggled to enabled, you can use the drop down menu to select a specific profile. The available profile types are:

- **AntiVirus**
- **WebFilter**
- **Application Control**
- **IPS**
- **DLP Sensor**
- **ICAP**
- **Web Application Firewall**

Just like with a regular policy, as soon as any of the **Security Profiles** is enabled, the following fields, with their own drop down menus for specific profiles will appear:

- **Proxy Options**
- **SSL/SSH Inspection**

14. Select **OK**.

To enable the explicit web proxy - CLI:

1. Enter the following command to turn on the IPv4 and IPv6 explicit web proxy for HTTP and HTTPS traffic.

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

You can also enter the following command to enable the web proxy for FTP sessions in a web browser.

```
config web-proxy explicit
  set ftp-over-http enable
end
```

The default explicit web proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit web proxy.

2. Enter the following command to enable the explicit web proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
  end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit web proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

The source address for a web-proxy security policy cannot be assigned to a FortiGate interface.

4. Optionally use the following command to add a destination URL that is only used by the explicit proxy. For example, to create an explicit policy that only allows access to Fortinet.com:

```
config firewall address
  edit Fortinet-web-sites
    set type url
    set url fortinet.com
  end
```

5. Use the following command to add an explicit web proxy policy that allows all users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set service webproxy
    set schedule always
```

```
end
```

6. Use the following command to add an explicit web proxy policy that allows authenticated users on the internal subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
edit 0
set proxy explicit-web
set dstintf wan1
set srcaddr Internal_subnet
set dstaddr Fortinet-web-sites
set action accept
set service webproxy
set schedule always
set groups <User group>
end
end
```

7. Use the following command to change global web proxy settings, for example to set the maximum request length for the explicit web proxy to 10:

```
config web-proxy global
set max-request-length 10
end
```

8. Determine whether or not to use Botnet feature.

The option `scan-botnet-connections` uses the following syntax:

```
config firewall proxy-policy
edit <policy id>
set scan-botnet-connections [disable|block|monitor]
end
```

Where:

- `disable` means do not scan connections to botnet servers
- `block` means block connection to botnet servers
- `monitor` means log connections to botnet servers

Policy Matching based on Referrer Headers and Query Strings

Web proxy policies support creating web proxy addresses to match referrer headers and query strings.

Matching referrer headers

For example, to create a web proxy address to match the referrer header to block access to the following YouTube URL `http://youtube.com/user/test321`. The http request will have the following format:

```
GET /user/test321 HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*
```

Create the following web proxy addresses to match this page:

```
config firewall proxy-address
edit youtube
```

```

        set type host-regex
        set host-regex ".*youtube.com"
    next
    edit test321
        set host "youtube"
        set path "/user/test321"
        set referrer enable
    end

```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the referrer header:

```

config firewall proxy-policy
    edit 1
        set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
        set proxy explicit-web
        set dstintf "wan2"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy-connect"
        set action accept
        set schedule "always"
        set utm-status enable
        set profile-protocol-options "test"
        set ssl-ssh-profile "test"
    next
    edit 2
        set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
        set proxy explicit-web
        set dstintf "wan2"
        set srcaddr "all"
        set dstaddr "test321"
        set service "webproxy"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "default"
        set profile-protocol-options "test"
        set ssl-ssh-profile "test"
    end

```

Matching query strings

To match the video with URL `youtube.com/watch?v=XXXXXXXXXX`, (where `XXXXXXXXXX` is an example YouTube query string) you need to match an HTTP request with the following format:

```

GET /user/watch?v=GLCHldlwQsg HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*

```

Create the following web proxy addresses to match this video or query string:

```

config firewall proxy-address
    edit "youtube"
        set uuid 4ad63880-971e-51e7-7b2e-c69423ac6314
        set type host-regex
        set host-regex ".*youtube.com"
    next

```

```

edit "query-string"
  set uuid 7687a8c0-9727-51e7-5063-05edda03abbf
  set host "youtube"
  set path "/watch"
  set query "v=XXXXXXXXX"
end

```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the query string

```

config firewall proxy-policy
  edit 1
    set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
    set proxy explicit-web
    set dstintf "wan2"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy-connect"
    set action accept
    set schedule "always"
    set utm-status enable
    set profile-protocol-options "test"
    set ssl-ssh-profile "test"
  next
  edit 2
    set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
    set proxy explicit-web
    set dstintf "wan2"
    set srcaddr "all"
    set dstaddr "query-string"
    set service "webproxy"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "default"
    set profile-protocol-options "test"
    set ssl-ssh-profile "test"
  next
end

```

Explicit Proxy Concepts

The following is information that is specific to Explicit Proxy concepts. Any information that is common to Web Proxy in general is covered in the more inclusive section of [Web Proxy Concepts on page 1187](#)

The FortiGate explicit web proxy

You can use the FortiGate explicit web proxy to enable explicit proxying of IPv4 and IPv6 HTTP, and HTTPS traffic on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI you can also configure the explicit web proxy to support SOCKS sessions from a web browser.

The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

If explicit web proxy options are not visible on the GUI, go to **System > Settings** and set the **Inspection mode** to **Proxy**. Then go to **System > Feature Visibility** and turn on **Explicit Proxy**.

In most cases you would configure the explicit web proxy for users on a network by enabling the explicit web proxy on the FortiGate interface connected to that network. Users on the network would configure their web browsers to use a proxy server for HTTP and HTTPS, FTP, or SOCKS and set the proxy server IP address to the IP address of the FortiGate interface connected to their network. Users could also enter the PAC URL into their web browser PAC configuration to automate their web proxy configuration using a PAC file stored on the FortiGate unit.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in transparent mode, users would configure their browsers to use a proxy server with the FortiGate management IP address.

If the FortiGate unit is operating with multiple VDOMs the explicit web proxy is configured for each VDOM.

The web proxy receives web browser sessions to be proxied at FortiGate interfaces with the explicit web proxy enabled. The web proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address. You can configure the explicit web proxy to keep the original client IP address. See [The FortiGate explicit web proxy on page 1200](#).

For more information about explicit web proxy sessions, see [The FortiGate explicit web proxy on page 1200](#).

Example explicit web proxy topology

To allow all explicit web proxy traffic to pass through the FortiGate unit you can set the explicit web proxy default firewall policy action to accept. However, in most cases you would want to use security policies to control explicit web proxy traffic and apply security features such as access control/authentication, virus scanning, web filtering, application control, and traffic logging. You can do this by keeping the default explicit web proxy security policy action to deny and then adding web-proxy security policies.

You can also change the explicit web proxy default security policy action to accept and add explicit web proxy security policies. If you do this, sessions that match web-proxy security policies are processed according to the security policy settings. Connections to the explicit web proxy that do not match a web-proxy security policy are allowed with no restrictions or additional security processing. This configuration is not recommended and is not a best practice.

The explicit web-proxy can accept VIP addresses for destination address. If an external IP matches a VIP policy, the IP is changed to the mapped-IP of the VIP.

Web-proxy policies can selectively accept or deny traffic, apply authentication, enable traffic logging, and use security profiles to apply virus scanning, web filtering, IPS, application control, DLP, and SSL/SSH inspection to explicit web proxy traffic.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit web proxy traffic. Web Proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **Any**. (On the

web-based manager you must set the interface to **Any**. In the CLI you must `unset the associated-interface`.)

Authentication of explicit web proxy sessions uses HTTP authentication and can be based on the user's source IP address or on cookies from the user's web browser. For more information, see [The FortiGate explicit web proxy on page 1200](#).

To use the explicit web proxy, users must add the IP address of a FortiGate interface on which the explicit web proxy is enabled and the explicit web proxy port number (default 8080) to the proxy configuration settings of their web browsers.

On FortiGate units that support it, you can also enable web caching for explicit web proxy sessions.

For the time being, traffic shaping is not supported per policy for explicit proxy. For explicit proxy traffic, traffic shaping can be carried out per interface.

Other explicit web proxy options

You can change the following explicit web proxy options as required by your configuration.

HTTP port, HTTPS port, FTP port, PAC port

The TCP port that web browsers use to connect to the explicit proxy for HTTP, HTTPS, FTP and PAC services. The default port is 8080 for all services. By default HTTPS, FTP, and PAC use the same port as HTTP. You can change any of these ports as required. Users configuring their web browsers to use the explicit web proxy should add the same port numbers to their browser configurations.

Multi-port support for Explicit Proxy

Support exists for the use of multiple ports and port range in the explicit FTP or Web proxies. These changes have been added in both CLI and GUI.

CLI:

```
set http-incoming-port <port_low>[-<port_high>]
```

Where:

- `port_low` - the low value of the port
- `port_high` - the high value of the port

The `port_high` value can be omitted if `port_low` and `port_high` are the same.

Proxy FQDN

Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.

Max HTTP request length

Enter the maximum length of an HTTP request in Kbytes. Larger requests will be rejected.

Max HTTP message length

Enter the maximum length of an HTTP message in Kbytes. Larger messages will be rejected.

Multiple incoming ports and port ranges

Web proxy can be configured to listen on multiple ports on the same IP as well as listen for HTTP and HTTPS on those same (or different) ports. This is done in the CLI.

Define the IP ranges using a hyphen (-). As shown below, `port_high` is not necessary to specify if `port_low` is equal to `port_high`.

CLI syntax

```
config web-proxy explicit
  set http-incoming-port <port_low> [-<port_high>]
end
```

Internet services

FortiOS can use the Internet Service Database (introduced in 5.4.1) as a web-proxy policy matching factor. This can only be done in the CLI.

CLI syntax:

```
config firewall proxy-policy
  edit 0
    set internet-service <application-id>
    set internet-service-custom <application-name>
```

IP Pools

IP Pools can be used with web proxy. When using this option of setting the IP pool name, the outgoing IP will be selected.

CLI syntax

```
config firewall proxy-policy
  edit <example>
    set poolname <name>
  end
```

Proxy chaining (web proxy forwarding servers)

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with an web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use

their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support authenticating with the remote forwarding server.

Adding a web proxy forwarding server

To add a forwarding server, select **Create New** in the **Web Proxy Forwarding Servers** section of the **Explicit Proxy** page by going to **Network > Explicit Proxy**.

Server Name	Enter the name of the forwarding server.
Proxy Address	Enter the IP address of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an FQDN or IP address.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down action	<p>Select what action the explicit web proxy to take if the forwarding server is down.</p> <p>Block means if the remote server is down block traffic.</p> <p>Use Original Server means do not forward traffic to the forwarding sever but instead forward it from the FortiGate to its destination. In other words operate as if there is no forwarding server configured.</p>
Enable Health Monitor	Select to enable health check monitoring and enter the address of a remote site. See "Web proxy forwarding server monitoring and health checking" .
Health Check Monitor Site	

Use the following CLI command to add a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

```
config web-proxy forward-server
edit fwd-srv
set addr-type fqdn
set fqdn proxy.example.com
set port 8080
end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. If the remote server does not respond it is assumed to be down. Checking continues and when the server does send a response the server is assumed to be back up. If you configure health checking, every 10 seconds the FortiGate unit attempts to get a response from a web server by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

Configure the server down action and enable health monitoring from the web-based manager by going to **Network > Explicit Proxy**, selecting a forwarding server, and changing the server down action and changing the health monitor settings.

Use the following CLI command to enable health checking for a web proxy forwarding server and set the server down option to bypass the forwarding server if it is down.

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  end
```

Grouping forwarding servers and load balancing traffic to them

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- **Weighted** load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- **Least-session** load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable **affinity**. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to **block** traffic or you can select to have the traffic **pass** through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Use the following command to add a forwarding server group that users weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to server2. The group has affinity enabled and blocks traffic if all of the forward servers are down:

```
config web-proxy forward-server
  edit server_1
    set ip 172.20.120.12
    set port 8080
  next
  edit server_2
    set ip 172.20.120.13
    set port 8000
  next
  edit server_3
    set ip 172.20.120.14
    set port 8090
  next
```

```
end
config web-proxy forward-server-group
edit New-fwd-group
set affinity enable
set ldb-method weight
set group-down-option block
config server-list
edit server_1
set weight 10
next
edit server_2
set weight 40
next
edit server_3
set weight 10
next
end
```

Adding proxy chaining to an explicit web proxy policy

You enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server - web-based manager:

1. Go to **Policy & Objects > Proxy Policy** and select **Create New**.
2. Configure the policy:

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT
Web Proxy Forwarding Server	Select, fwd-srv

3. Select **OK** to save the security policy.

To add an explicit web proxy forwarding server - CLI:

1. Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named `fwd-srv`

```
config firewall proxy-policy
edit 0
set proxy explicit-web
```

```
set dstintf wan1
set scraddr Internal_subnet
set dstaddr all
set action accept
set schedule always
set webproxy-forward-server fwd-srv
end
```

Security profiles, threat weight, device identification, and the explicit web proxy

You can apply all security profiles to explicit web proxy sessions. This includes antivirus, web filtering, intrusion protection (IPS), application control, data leak prevention (DLP), and SSL/SSH inspection. Security profiles are applied by selecting them in an explicit web proxy policy or in authentication rules added to web proxy policies.

Traffic accepted by explicit web proxy policies contributes to threat weight data.

The explicit web proxy is not compatible with device identification.

Since the traffic accepted by the explicit web proxy is known to be either HTTP, HTTPS, or FTP over HTTP and since the ports are already known by the proxy, the explicit web proxy does not use all of the SSL/SSH inspection options. The explicit web proxy does support the following proxy options:

- Enable chunked bypass
- HTTP oversized file action and threshold

The explicit web proxy does not support the following proxy options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit web proxy users are not added to dashboard usage and log and archive statistics widgets.

For explicit web proxy sessions, the FortiGate unit applies antivirus scanning to HTTP POST requests and HTTP responses. The FortiGate unit starts virus scanning a file in an HTTP session when it receives a file in the body of an HTML request. The explicit web proxy can receive HTTP responses from either the originating web server or the FortiGate web cache module.

Explicit web proxy sessions and user limits

Web browsers and web servers open and close multiple sessions with the explicit web proxy. Some sessions open and close very quickly. HTTP 1.1 keepalive sessions are persistent and can remain open for long periods of time. Sessions can remain on the explicit web proxy session list after a user has stopped using the proxy (and has, for example, closed their browser). If an explicit web proxy session is idle for more than 3600 seconds it is torn down by the explicit web proxy. See [RFC 2616](#) for information about HTTP keepalive/persistent HTTP sessions.

This section describes proxy sessions and user limits for both the explicit web proxy and the explicit FTP proxy. Session and user limits for the two proxies are counted and calculated together. However, in most cases if both proxies are active there will be many more web proxy sessions than FTP proxy sessions.

The FortiGate unit adds two sessions to its session table for every explicit proxy session started by a web browser and every FTP session started by an FTP client. An entry is added to the session table for the session from the web browser or client to the explicit proxy. All of these sessions have the same destination port as the explicit web proxy port (usually 8080 for HTTP and 21 for FTP). An entry is also added to the session table for the session between the exiting FortiGate interface and the web or FTP server destination of the session. All of these

sessions have a FortiGate interface IP address and the source address of the session and usually have a destination port of 80 for HTTP and 21 for FTP.

Proxy sessions that appear in FortiView do not include the Policy ID of the web-proxy or ftp-proxy security policy that accepted them. However, the explicit proxy sessions include a destination port that matches the explicit proxy port number (usually 8080 for the web proxy and 21 for the FTP proxy). The proxied sessions from the FortiGate unit have their source address set to the IP address of the FortiGate unit interface that the sessions use to connect to their destinations (for example, for connections to the Internet the source address would be the IP address of the FortiGate interface connected to the Internet).

FortiOS limits the number of explicit proxy users. This includes both explicit FTP proxy and explicit web proxy users. The number of users varies by FortiGate model from as low as 10 to up to 18000 for high end models. You cannot raise this limit.

If your FortiGate unit is configured for multiple VDOMs you can go to **System > Global Resources** to view the maximum number of **Concurrent explicit proxy users** and optionally reduce the limit. You can also use the following command:

```
config global
  config system resource-limits
    set proxy 50
  end
end
```

To limit the number of explicit proxy users for a VDOM, from the web-based manager enable multiple VDOMs and go to **System > VDOM** and edit a VDOM or use the following command to change the number of explicit web proxy users for VDOM_1:

```
config global
  config system vdom-property
    edit VDOM_1
      set proxy 25
    end
  end
end
```

You can use the `diagnose wad user list` command to view the number of explicit web proxy users. Users may be displayed with this command even if they are no longer actively using the proxy. All idle sessions time out after 3600 seconds.

You can use the command `diagnose wad user clear` to clear current explicit proxy users. You can also use the command `diagnose wad user clear <user-name>` to clear individual users. This means delete information about all users and force them re-authenticate.

Users that authenticate with explicit web-proxy or ftp-proxy security policies do not appear in the **Monitor > Firewall User Monitor** list and selecting **De-authenticate All Users** has no effect on explicit proxy users.

How the number of concurrent explicit proxy users is determined depends on their authentication method:

- For session-based authenticated users, each authenticated user is counted as a single user. Since multiple users can have the same user name, the proxy attempts to identify users according to their authentication membership (based upon whether they were authenticated using RADIUS, LDAP, FSAE, local database etc.). If a user of one session has the same name and membership as a user of another session, the explicit proxy assumes this is one user.

- For IP Based authentication, or no authentication, or if no web-proxy security policy has been added, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

The explicit proxy does not limit the number of active sessions for each user. As a result the actual explicit proxy session count is usually much higher than the number of explicit web proxy users. If an excessive number of explicit web proxy sessions is compromising system performance you can limit the amount of users if the FortiGate unit is operating with multiple VDOMs.

Explicit Proxy Configuration

The following is information that is specific to Explicit Proxy configuration. Any configuration information that is common to Web Proxy in general is covered in the more inclusive section of [Web Proxy Configuration on page 1194](#).

Configuring an external IP address for the IPv4 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
  set status enable
  set outgoing-ip <ip1> <ip2> ... <ipN>
end
```

Configuring an external IP address for the IPv6 explicit web proxy

You can use the following command to set an external IP address (or pool) that will be used by the explicit web proxy policy.

```
config web-proxy explicit
  set status enable
  set outgoing-ipv6 <ip1> <ip2> ... <ipN>
end
```

Restricting the IP address of the IPv4 explicit web proxy

You can use the following command to restrict access to the explicit web proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit web proxy:

```
config web-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the IPv4 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit web proxy is

enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config web-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy to use only one IPv6 IP address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 web proxy:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit web proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config web-proxy explicit
  set outgoing-ipv6 2001:db8:0:2::50
end
```

Explicit proxy firewall address types

Explicit proxy firewall address types improve granularity over header matching for explicit web proxy policies. You can enable this option using the **Show in Address List** button on the Address and Address Group New/Edit forms under **Policy & Objects > Addresses**.

The following address types are available:

- **URL Pattern** - destination address
- **Host Regex Match** - destination address
- **URL Category** - destination address (URL filtering)
- **HTTP Method** - source address
- **User Agent** - source address
- **HTTP Header** - source address
- **Advanced (Source)** - source address (combines User Agent, HTTP Method, and HTTP Header)
- **Advanced (Destination)** - destination address (combines Host Regex Match and URL Category)

Proxy auto-config (PAC) configuration

A proxy auto-config (PAC) file defines how web browsers can choose a proxy server for receiving HTTP content. PAC files include the FindProxyForURL(url, host) JavaScript function that returns a string with one or more access method specifications. These specifications cause the web browser to use a particular proxy server or to connect directly.

To configure PAC for explicit web proxy users, you can use the port that PAC traffic from client web browsers use to connect to the explicit web proxy. explicit web proxy users must configure their web browser's PAC proxy settings to use the PAC port.

PAC File Content

You can edit the default PAC file from the web-based manager or use the following command to upload a custom PAC file:

```
config web-proxy explicit
    set pac-file-server-status enable
    set pac-file-data <pac_file_str>
end
```

Where <pac_file_str> is the contents of the PAC file. Enter the PAC file text in quotes. You can copy the contents of a PAC text file and paste the contents into the CLI using this option. Enter the command followed by two sets of quotes then place the cursor between the quotes and paste the file content.

The maximum PAC file size is 256 kbytes. If your FortiGate unit is operating with multiple VDOMs each VDOM has its own PAC file. The total amount of FortiGate memory available to store all of these PAC files 2 MBytes. If this limit is reached you will not be able to load any additional PAC files.

You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file.

To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default FortiGate PAC file URL is:

```
http://<interface_ip>:<PAC_port_int>/<pac_file_str>
```

For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit web proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be:

```
http://172.20.120.122:8080/proxy.pac
```

From the CLI you can use the following command to display the PAC file URLs:

```
get web-proxy explicit
```

Unknown HTTP version

You can select the action to take when the proxy server must handle an unknown HTTP version request or message. Set unknown HTTP version to Reject or Best Effort. Best Effort attempts to handle the HTTP traffic as best as it can. Reject treats known HTTP traffic as malformed and drops it. The Reject option is more secure.

Authentication realm

You can enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the realm includes spaces enclose it in quotes. When a user authenticates with the explicit web

proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.

Implementing Botnet features

The option `scan-botnet-connections` can be added to an explicit proxy policy.

CLI Syntax:

```
config firewall proxy-policy
  edit <policy_id>
    set scan-botnet-connections [disable|block|monitor]
  end
```

where:

- `disable` means do not scan connections to botnet servers.
- `block` means block connections to botnet servers.
- `monitor` means log connections to botnet servers.

Adding disclaimer messages to explicit proxy policies

This feature allows you to create user exceptions for specific URL categories (including warning messages) based on user groups. The **Disclaimer Options** are configured under **Policy & Objects > Proxy Policy**.

You can also configure a disclaimer for each Authentication Rule by setting **Action** to **Authenticate**.

Disclaimer explanations

- **Disable:** No disclaimer (default setting).
- **By Domain:** The disclaimer will be displayed on different domains. The explicit web proxy will check the referring header to mitigate the javascript/css/images/video/etc page.
- **By Policy:** The disclaimer will be displayed if the HTTP request matches a different explicit firewall policy.
- **By User:** The disclaimer will be displayed when a new user logs on.

Changing HTTP headers

You can create explicit web proxy profiles that can add, remove and change HTTP headers. The explicit web proxy profile can be added to a web explicit proxy policy and will be applied to all of the HTTP traffic accepted by that policy.

You can change the following HTTP headers:

- `client-ip`
- `via` header for forwarded requests
- `via` header for forwarded responses
- `x-forwarded-for`
- `front-end-https`

For each of these headers you can set the action to:

- Pass to forward the traffic without changing the header
- Add to add the header

- Remove to remove the header

You can also configure how the explicit web proxy handles custom headers. The proxy can add or remove custom headers from requests or responses. If you are adding a header you can specify the content to be included in the added header.

Create web proxy profiles from the CLI:

```
config web-proxy profile
  edit <name>
    set header-client-ip {add | pass | remove}
    set header-via-request {add | pass | remove}
    set header-via-response {add | pass | remove}
    set header-x-forwarded-for {add | pass | remove}
    set header-front-end-https {add | pass | remove}
    config headers
      edit <id>
        set action {add-to-request | add-to-response | remove-from-request |
          remove-from-response}
        set content <string>
        set name <name>
      end
    end
  end
```

Use the following command to add a web proxy profile to an explicit proxy policy:

```
config firewall proxy-policy
  edit <id>
    set webproxy-profile <name>
  end
```

Preventing the explicit web proxy from changing source addresses

By default in NAT mode the explicit web proxy changes the source address of packets leaving the FortiGate to the IP address of the FortiGate interface that the packets are exiting from. In Transparent mode the source address is changed to the management IP.

This configuration hides the IP addresses of clients and allows packets to return to the FortiGate unit interface without having to route packets from clients. You can use the following command to configure the explicit web proxy to keep the original client's source IP address:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set transparent enable
  end
```

Example users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering, and virus scanning

This example describes how to configure the explicit web proxy for the example network shown below. In this example, users on the internal network connect to the explicit web proxy through the Internal interface of the FortiGate unit. The explicit web proxy is configured to use port 8888 so users must configure their web browser proxy settings to use port 8888 and IP address 10.31.101.100.

Example explicit web proxy network topology

Explicit web proxy users must authenticate with a RADIUS server before getting access to the proxy. The explicit proxy policy that accepts explicit web proxy traffic applies per session authentication and includes a RADIUS server user group. The authentication rule also applies web filtering and virus scanning.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit web proxy for HTTP and HTTPS and change the HTTP and HTTPS ports to 8888.
2. Enable the explicit web proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit web proxy.
4. Add an authentication explicit proxy policy. Enable web caching. Add an authentication rule and enable antivirus and web filtering.

Configuring the explicit web proxy - web-based manager

Use the following steps to configure the explicit web proxy.

To enable and configure the explicit web proxy

1. Go to **System > Feature Visibility** and turn on the **Explicit Proxy** feature.
2. Go to **Network > Explicit Proxy** and change the following settings:

Enable Explicit Web Proxy	Select HTTP/HTTPS .
Listen on Interfaces	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
HTTP Port	8888
HTTPS Port	0
Realm	You are authenticating with the explicit web proxy.
Default Firewall Policy Action	Deny

3. Select **Apply**.

To enable the explicit web proxy on the Internal interface

1. Go to **Network > Interfaces**.
2. Edit the internal interface.
3. Select **Enable Explicit Web Proxy**.
4. Select **OK**.

To add a RADIUS server and user group for the explicit web proxy

1. Go to **User & Device > RADIUS Servers** and select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

2. Select **OK**.

3. Go to **User & Device > User Groups** and select **Create New** to add a new user group.

Name	Explicit_proxy_user_group
Type	Firewall
Remote Groups	RADIUS_1
Group Name	Any

4. Select **OK**.

To add an explicit proxy policy

1. Go to **Policy & Objects > Addresses** and select **Create New**.

2. Add a firewall address for the internal network:

Category	Address
Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Proxy Policy** and select **Create New**.

4. Configure the explicit web proxy policy.

Explicit Proxy Type	Web
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

5. Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
---------------	-----------------

Source User(s)	Leave blank
Schedule	always

6. Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
7. Select the **default** proxy options profile.
8. Select **OK**.
9. Make sure **Enable IP Based Authentication** is not selected.
10. Turn on **Web Cache**.
11. Select **OK**.

Configuring the explicit web proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable the explicit web proxy on the Internal interface

1. Enter the following command to enable the explicit web proxy on the internal interface.

```
config system interface
edit internal
set explicit-web-proxy enable
end
```

To enable and configure the explicit web proxy

1. Enter the following command to enable the explicit web proxy and set the TCP port that proxy accepts HTTP and HTTPS connections on to 8888.

```
config web-proxy explicit
set status enable
set http-incoming-port 8888
set https-incoming-port 8888
set realm "You are authenticating with the explicit web proxy"
set sec-default-action deny
end
```

To add a RADIUS server and user group for the explicit web proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
edit RADIUS_1
set server 10.31.101.200
set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
edit Explicit_proxy_user_group
set group-type firewall
set member RADIUS_1
end
```

To add a security policy for the explicit web proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
edit Internal_subnet
set type iprange
set start-ip 10.31.101.1
set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit web proxy security policy:

```
config firewall proxy-policy
edit 0
set proxy explicit-web
set dstintf wan1
set srcaddr Internal_subnet
set dstaddr all
set action accept
set service webproxy
set webcache enable
set identity-based enable
set ipbased disable
set active-auth-method basic
set groups <User group>
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

To test the explicit web proxy configuration

1. Configure a web browser on the internal subnet to use a web proxy server at IP address 10.31.101.100 and port 8888.
2. Browse to an Internet web page.
The web browser should pop up an authentication window that includes the phrase that you added to the Realm option.
3. Enter the username and password for an account on the RADIUS server.
If the account is valid you should be allowed to browse web pages on the Internet.
4. Close the browser and clear its cache and cookies.
5. Restart the browser and connect to the Internet.
You could also start a second web browser on the same PC. Or you could start a new instance of the same browser as long as the browser asks for a user name and password again.

You should have to authenticate again because identity-based policies are set to session-based authentication.

6. If this basic functionality does not work, check your FortiGate and web browser configuration settings.
7. Browse to a URL on the URL filter list and confirm that the web page is blocked.
8. Browse to <http://eicar.org> and attempt to download an anti-malware test file.
The antivirus configuration should block the file.
Sessions for web-proxy security policies do not appear on the Top Sessions dashboard widget and the count column for security policies does not display a count for explicit web proxy security policies.
9. You can use the following command to display explicit web proxy sessions

```
get test wad 60
IP based users:

Session based users:
  user:0x9c20778, username:User1, vf_id:0, ref_cnt:9

Total allocated user:1

Total user count:3, shared user quota:50, shared user count:3
```

This command output shows one explicit proxy user with user name `User1` authenticated using session-based authentication.

Kerberos and NTLM authentication

FortiOS recognizes the client's authentication method from the token and selects the correct authentication scheme to authenticate successfully.

CLI syntax

```
config firewall proxy-policy
edit 0
  set active-auth-method [ntlm|basic|digest|negotiate|none]
end
```

Kerberos authentication for explicit proxy users

Kerberos authentication is a method for authenticating both explicit web proxy and transparent web proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

Enhancements to Kerberos explicit and transparent web proxy

FortiOS 5.6.x authentication is managed by schemes and rules based on protocol and source address. As such, configurable authentication settings have been introduced to enhance authentication.

CLI commands (`config authentication rule, scheme, and setting`) allow explicit proxy rules and schemes to be created to separate user authentication (e.g. authentication rules and schemes used to match conditions in order to identify users) from user authorization (proxy-based policies with users and/or user groups).

CLI syntax - config authentication rule

```
config authentication rule
edit <name>
  set name <name>
  set status {enable|disable}
  set protocol {http|ftp|socks}
  config srcaddr <addr-name or addrgrp-name>
    edit <name>
      set name <ipv4-policy-name>
    next
```

```

end
config srcaddr6 <addr-name or addrgrp-name>
  edit <name>
    set name <ipv6-policy-name>
  next
end
set ip-based {enable|disable}
set active-auth-method <scheme-name>
set sso-auth-method <scheme-name>
set transaction-based {enable|disable} - basic scheme + session-based
set web-auth-cookie {enable|disable}
set comments <comments>
next
end

```

Note: As shown above, HTTP, FTP, and SOCKSv5 authentication protocols are supported for explicit proxy.

Authentication rules are used to receive user-identity, based on the values set for protocol and source address. Having said this, if a rule fails to match based on source address, there will be no other attempt to match the rule, however the next policy will be attempted. This occurs only when:

- there is an authentication rule, but no authentication method has been set (under `config authentication scheme`; see below), so user identity cannot be found.
- the user is successfully matched in the rule, but fails to match the current policy.

Once a rule is positively matched through protocol and/or source address, it must also match the authentication method specified (`active-auth-method` and `sso-auth-method`). These methods point to schemes, as defined under `config authentication scheme`.

CLI syntax - config authentication scheme

```

config authentication scheme
  edit <name>
    set name <name>
    set method {basic|digest|ntlm|form|negotiate|fsso|rsso}
    set negotiate-ntlm {enable|disable}
    set require-tfa {enable|disable}
    set fsso-guest {enable|disable}
    config user-database
      edit <name>
        set name {local|<ldap-server>|<radius-server>|<fsso-name>|<rsso-name>|<tacacs+-name>}
      next
    end
  next
end

```

Combining authentication rules and schemes, granular control can be exerted over users and IPs, creating an efficient process for users to successfully match a criteria before matching the policy.

Additional options can be set under `config authentication setting`.

CLI syntax - config authentication setting

```

config authentication setting
  set sso-scheme <scheme-name>
  set active-scheme <scheme-name>
  set captive-portal <host-name>

```

```
set captive-portal-port <tcp-port>
end
```

Integration of Transparent and Explicit proxy HTTP policy checking

A CLI command, under `config firewall profile-protocol-options`, allows HTTP policy checking to be enable or disabled. When enabled, transparent traffic can be matched in a firewall policy and policy user authentication can occur. In addition, separate SSL inspection policies can be created:

```
config firewall profile-protocol-options
edit <name>
set http-policy {enable|disable}
end
```

Internet Service Database in Explicit/Implicit proxy policies

CLI commands, under `config firewall proxy-policy`, implement the Internet Service Database (ISDB) as the webproxy matching factor, and override IP pool is also support:

```
config firewall proxy-policy
edit <name>
set proxy {explicit-web|transparent-web|ftp|wanopt}
set dstintf <dst-name>
set poolname <ip-pool-name>
end
```

Multiple port/port range support for explicit web and explicit FTP proxy

Multiple port numbers and/or ranges can be set for explicit proxy, specifically for HTTP/HTTPS and FTP. Go to **Network > Explicit Proxy** and configure settings under **Explicit Web Proxy** and **Explicit FTP Proxy**, or under `config web-proxy explicit` in the CLI Console.

1. General configuration

1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testtgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
 - The account only requires “domain users” membership
 - Password set to never expire
 - Set a very strong password

1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., TESTFGT.TEST.COM 10.10.1.10

1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

The realm name is always presented in uppercase, and prefixed with the “@” character.

1.5 Encode base64

Use the *base64* command (available in most Linux distros) command to encode the *fgt.keytab* file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

2. FortiGate configuration

2.1 Create LDAP Server instance

```
config user ldap
  edit "ldap" <<< Required for authorization
    set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
    set cnid "cn"
    set dn "dc=test,dc=com"
    set type regular
    set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
    set password <FOOS>
  next
end
```

2.2 Define Kerberos as an authentication service

```
config user krb-keytab
  edit "http_service"
    set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
    set ldap-server "ldap" <<< the defined ldap server for authorization
    set keytab
      "BQIAAABNAAIACkJFUkJFU15DT00ABEhUVFAAGlRPTl1fRkdUXzEwMERfQS5CRVJCVRViuQ09NAAAAQA
      AAAKABcAEJQl0MHgovwplu7XzfENJzw=" <<< base64 encoding keytab data, created in step 1.5
  next
end
```

2.3 Create user group(s)

```
config user group <<< the group is used for kerberos authentication
  edit "testgrp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap" <<< Same as ldap-server option in krb-keytab
        set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
      next
    end
  next
end
```

2.4 Create firewall policy

```
config firewall proxy-policy
  edit 1
    set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set groups "CN=USERS LAB.PS FSSO"
  next
end
```

2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```
Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2 0 0 Fri Dec 2 10:06:43 2016 60 .
drwxrwxrwt 22 0 0 Tue Dec 6 14:28:29 2016 3280 ..
-rw-r--r-- 1 0 0 Fri Dec 2 10:06:43 2016 392 1.0.89.keytab
```

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

3. Client side walkthrough

3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```
C:\Users\glenk>klist Cached Tickets: (5)

C:\Users\glenk>klist
Cached Tickets: (5)
#0> Client: glenk @ home.local

    Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
    KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
    Ticket Flags 0x60a00000 -> forwardable forwarded renewable pre_authent
    Start Time: 12/6/2016 14:58:06 (local)
    End Time: 12/7/2016 0:58:04 (local)
    Renew Time: 12/13/2016 14:58:04 (local)
    Session Key Type: AES-256-CTS-HMAC-SHA1-96

#1> Client: glenk @ home.local

    Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
    KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
    Ticket Flags 0x40e00000 -> forwardable renewable initial pre_authent
    Start Time: 12/6/2016 14:58:04 (local)
    End Time: 12/7/2016 0:58:04 (local)
    Renew Time: 12/13/2016 14:58:04 (local)
    Session Key Type: AES-256-CTS-HMAC-SHA1-96

#2> Client: glenk @ home.local

    Server: cifs/EthicsGradient.home.local @ HOME.LOCAL
    KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
    Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
    Start Time: 12/6/2016 14:58:06 (local)
    End Time: 12/7/2016 0:58:04 (local)
    Renew Time: 12/13/2016 14:58:04 (local)
    Session Key Type: AES-256-CTS-HMAC-SHA1-96

#3> Client: glenk @ home.local

    Server: ldap/EthicsGradient.home.local @ HOME.LOCAL
```

```

KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
Start Time: 12/6/2016 14:58:06 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: AES-256-CTS-HMAC-SHA1-96

#4> Client: glenk @ home.local

Server: LDAP/EthicsGradient.home.local/home.local @ HOME.LOCAL
KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
Ticket Flags 0x40a40000 -> forwardable renewable pre_authent ok_as_delegate
Start Time: 12/6/2016 14:58:06 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: AES-256-CTS-HMAC-SHA1-96

```

3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As "Negotiate" is set, the client has knowledge of the KRBTGT, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *reg-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

This ticket is then available on the client.

In the example below, the ticket-granted-service has issued Ticket #2.

```

#2> Client: glenk @ home.local
Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
Start Time: 12/6/2016 14:59:45 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: RSADSI RC4-HMAC(NT)

```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

Transparent web-proxy Kerberos authentication

Transparent web-proxy is new to FortiOS 5.6, in which the FortiGate can process level 7 policy matching, even when the explicit web-proxy is not enabled on the client's browser. The transparent web-proxy policy is set in proxy-policy too. The policy matching rule is the same as the explicit web-proxy.

In the firewall policy level, transparent web-proxy is regarded as a special UTM. The HTTP/HTTPS traffic matches the firewall policy first, then traffic is redirected to the web-proxy daemon. If the transparent web-proxy feature is disabled, http-policy options in profile-protocol-options is used to enable transparent web-proxy feature.

IP-based

1. Captive portal and the captive portal port must be configured in transparent web-proxy for support of Kerberos authentication:

```
config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end
```

2. Authentication rule, scheme, and krb-keytab need to be configured for Kerberos authentication (note the active-auth-method scheme referenced in the rule):

```
config authentication scheme
    edit <kerberos-scheme>
        set method negotiate
        set negotiate-ntlm <enable>
        set fsso-guest <disable>
    next
end

config authentication rule
    edit <name>
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <enable>
        set active-auth-method <kerberos-scheme>
    next
end

config user krb-keytab
    edit <name>
        set principal "HTTP/TESTFGT.TEST.COM@TEST.COM"
        set ldap-server "ldap"
        set keytab <base64-encoding-keytab-data>
    next
end
```

3. Configure LDAP and user group used for authorization:

```
config user ldap
    edit "ldap"
        set server "10.10.1.1"
        set cnid
        set dn
        set type <regular>
        set username "CN=admin,CN=Users,DC=test,DC=com"
```

```

        set password ENC
        aW5lIAHkPMf4D+ZCKpGMU3x8Fpq0G+7uIbAvpblbXFA5vLfGb4/oRBx+B6R/v+CMCetP84e+Gdz5zEcM
        yOd3cj0BoIhFrpYJfXhRs4lSE0HezeVXfxwTSf5VJG+F11G/G5RpaY+AE8bortC8MBE7P2/uGQocFHu4
        Ilulp5I60Jvyk6Ei3hDZMjTd8iPp5IkRJZVVjQ==
    next
end

config user group
    edit "testgrp"
        set member "ldap"
        config match
            edit "1"
                set server-name "ldap"
                set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
            next
        end
    next
end

```

4. Create proxy-policy, with groups as the authorizing policy-matching element:

```

config firewall proxy-policy
    edit 1
        set uuid 1bbb891a-9cd2-51e7-42ff-d1fa13cac3da
        set proxy explicit-web
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set groups testgrp
    next
end

```

5. UTM must be enabled in the firewall policy to support the transparent web-proxy:

```

config firewall policy
    edit "1"
        set name "policy1"
        set uuid 8a6ceeac-b016-51e6-2b5c-165070d5bf50
        set srcintf "mgmt1"
        set dstintf "mgmt1"
        set srcaddr "all"
        set dstaddr "all"
        set action <accept>
        set schedule "always"
        set service "ALL"
        set utm-status <enable>
        set profile-protocol-options "transparent-web-proxy"
        set ssl-ssh-profile "deep-inspection"
        set nat <enable>
    next
end

config firewall profile-protocol-options
    edit "transparent-web-proxy"
        config http
            set ports "80 8080"

```

```

        unset options
        set http-policy enable
        unset post-lang
    end
    ...
next
end

```

Session-based with web-auth cookie

The web-auth-cookie feature is necessary for session-based authentication under transparent web-proxy.

The configuration is the same as for IP-based authentication, except `ip-based` is disabled in the authentication rule:

```

config authentication rule
    edit "kerberos-rules"
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <disable>
        set active-auth-method <kerberos-scheme>
    next

config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end

```

Transparent Proxy Concepts

In addition to the Explicit Web Proxy, FortiOS supports a Transparent web proxy. While it does not have as many features as Explicit Web Proxy, the transparent proxy has the advantage that nothing needs to be done on the user's system to forward supported web traffic over to the proxy. There is no need to reconfigure the browser or publish a PAC file. Everything is transparent to the end user, hence the name. This makes it easier to incorporate new users into a proxy deployment.

You can use the transparent proxy to apply web authentication to HTTP traffic accepted by a firewall policy. In previous versions of FortiOS, web authentication required using the explicit proxy.

Normal FortiOS authentication is IP address based. Users are authenticated according to their IP address and access is allowed or denied based on this IP address. On networks where authentication based on IP address will not work you can use the Transparent Web proxy to apply web authentication that is based on the user's browser and not on their IP address. This authentication method allows you to identify individual users even if multiple users on your network are connecting to the FortiGate from the same IP address.

More about the transparent proxy

The following changes are incorporated into Transparent proxy, some of which affect Explicit Web Proxy as well.

Flat policies

The split policy feature has been removed. This will make the explicit policy more like the firewall policy.

Authentication

The authentication design is intended to separate authentication from authorization. Authentication has been moved into a new table in the FortiOS. This leaves the authorization as the domain of the explicit proxy policy.

Previously, if authentication was to be used:

1. The policy would be classified as an identity based policy
2. The policy would be split to add the authentication parameters
3. The authentication method would be selected
4. The user/group would be configured

Now:

The user/group is configured in the proxy policy

1. A new authentication rule is added
2. This option refers to the authentication scheme
3. The authentication scheme has the details of the authentication method

The new authentication work flow for Transparent Proxy:

Toggle the transparent-http-policy match:

```
config firewall profile-protocol-options
  edit <profile ID>
    config http
      set http-policy <enable|disable>
```

If disabled, everything works like before. If enabled, the authentication is triggered differently.

- http-policy work flow:
- For transparent traffic, if there is a regular firewall policy match, when the Layer 7 check option is enabled, traffic will be redirected to WAD for further processing.
- For redirected traffic, layer 7 policy (HTTP policy) will be used to determine how to do security checks.
- If the last matching factor is down to user ID, then it will trigger a new module to handle the L7 policy user authentication.
- Then propagate learned user information back to the system so that it can be used to match traffic for L4 policy.

New Proxy Type

There is a new subcategory of proxy in the proxy policy called **Transparent Web**. The old **Web Proxy** is now referred to as **Explicit Web Proxy**.

- This is set in the firewall policy
- It is available when the HTTP policy is enabled in the profile-protocol options for the firewall policy
- This proxy type supports OSI layer 7 address matching.
- This proxy type should include a source address as a parameter
- Limitations:
 - It can be used for HTTPS traffic, if deep scanning is not used
 - It only supports SNI address matching, i.e. domain names
 - It does not support header types of address matching
 - It only supports SSO authentication methods, no active authentication methods.

IP pools support

Proxies are now supported on outgoing IP pools.

SOCKSv5

SOCKSv5 authentication is now supported for explicit proxies.

To configure:

```
config authentication rule
edit <name of rule>
set protocol socks
end
```

Forwarding

Proxies support URL redirect/forwarding. This allows a non-proxy forwarding server to be assigned a rule that will redirect web traffic from one URL to another, such as redirecting traffic destined for youtube.com to restrict.youtube.com.

- A new option called "Redirect URL" has been added to the policy
- Traffic forwarding by VIP is supported

Support for explicit proxy address objects & groups into IPv4 firewall policies

This would allow the selection of web filter policy, SSL inspection policy, and proxy policy based on source IP + destination (address|explicit proxy object|category|group of any of those). This enables things like “do full SSL interception on www.google.com, but not the rest of the Search Engines category”.

Support application service in the proxy based on HTTP requests.

The application service can be configured using the following CLI commands:

```
config firewall service custom
edit <name of service>
set explicit-proxy enable
set app-service-type <disable|app-id|app-category>
set app-category <application category ID, integer>
set application <application ID, integer>
end
```

Transparent Proxy Configuration

To implement the Transparent proxy, go to **System > Settings** and scroll down to **Operations Settings** and set the inspection mode to **Proxy**.

Then go to **System > Feature Visibility** and enable **Explicit Proxy**.

Then go to **Security Profiles > Proxy Options**, edit a proxy options profile and under **Web Options** enable **HTTP Policy Redirect**.

Then go to **Policy & Objects > IPv4 Policy** and create or edit a policy that accepts traffic that you want to apply web authentication to. This can be a general policy that accepts many different types of traffic as long as it also accepts the web traffic that you want to apply web authentication to.

Select a **Security Profile** and select the **Proxy Options** profile that you enabled **HTTP Policy Redirect** for.

Name 	General Internet Access Policy	
Incoming Interface	 port2	▼

CLI changes due to addition of Transparent Proxy

The adding of Transparent Proxy to the existing proxy types has required some changes, removals, moves and additions to the CLI.

Changes:

Previous	New
<code>config firewall explicit-proxy-policy</code>	<code>config firewall proxy-policy</code>

Previous	New
<code>config firewall explicit-proxy-address</code>	<code>config firewall proxy-address</code>
<code>config firewall explicit-proxy-addrgrp</code>	<code>config firewall proxy-addrgrp</code>
<pre>config firewall explicit-proxy-policy edit <policy ID> set proxy web end</pre>	<pre>config firewall proxy-policy edit <policy ID> set proxy explicit-web end</pre>

FTP Proxy Concepts

The FortiGate explicit FTP proxy

You can use the FortiGate explicit FTP proxy to enable explicit FTP proxying on one or more FortiGate interfaces. The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Explicit FTP proxies are configured for each VDOM when multiple VDOMs are enabled.

In most cases you would configure the explicit FTP proxy for users on a network by enabling the explicit FTP proxy on the FortiGate interface connected to that network. Users on the network would connect to and authenticate with the explicit FTP proxy before connecting to an FTP server. In this case the IP address of the explicit FTP proxy is the IP address of the FortiGate interface on which the explicit FTP proxy is enabled.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The FTP proxy receives FTP sessions to be proxied at FortiGate interfaces with the explicit FTP proxy enabled. The FTP proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit FTP proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address.

Example explicit FTP proxy topology

To allow anyone to anonymously log into explicit FTP proxy and connect to any FTP server you can set the explicit FTP proxy default firewall proxy action to accept. When you do this, users can log into the explicit FTP proxy with any username and password.

In most cases you would want to use explicit proxy policies to control explicit FTP proxy traffic and apply security features, access control/authentication, and logging. You can do this by keeping the default explicit FTP proxy firewall policy action to deny and then adding explicit FTP proxy policies. In most cases you would also want users to authenticate with the explicit FTP proxy. By default an anonymous FTP login is required. Usually you would add authentication to explicit FTP proxy policies. Users can then authenticate with the explicit FTP proxy according to users or user groups added to the policies. User groups added to explicit FTP proxy policies can use any authentication method supported by FortiOS including the local user database and RADIUS and other remote servers.

If you leave the default firewall policy action set to deny and add explicit FTP proxy policies, all connections to the explicit FTP proxy must match an or else they will be dropped. Sessions that are accepted are processed according to the ftp-proxy security policy settings.

You can also change the explicit FTP proxy default firewall policy action to accept and add explicit FTP proxy policies. If you do this, sessions that match explicit FTP proxy policies are processed according to the policy settings. Connections to the explicit FTP proxy that do not match an explicit FTP proxy policy are allowed and the users can authenticate with the proxy anonymously.

There are some limitations to the security features that can be applied to explicit FTP proxy sessions. See [The FortiGate explicit FTP proxy on page 1233](#).

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit FTP proxy traffic. Explicit FTP proxy policies can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to **any**. (On the web-based manager you must set the interface to **Any**. In the CLI you must `unset the associated-interface`.)

How to use the explicit FTP proxy to connect to an FTP server

To connect to an FTP server using the explicit FTP proxy, users must run an FTP client and connect to the IP address of a FortiGate interface on which the explicit FTP proxy is enabled. This connection attempt must use the configured explicit FTP proxy port number (default 21).

The explicit FTP proxy is not compatible with using a web browser as an FTP client. To use web browsers as FTP clients configure the explicit web proxy to accept FTP sessions.

The following steps occur when a user starts an FTP client to connect to an FTP server using the explicit FTP proxy. Any RFC-compliant FTP client can be used. This example describes using a command-line FTP client. Some FTP clients may require a custom FTP proxy connection script.

1. The user enters a command on the FTP client to connect to the explicit FTP proxy.

For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

```
ftp 10.31.101.100
```

2. The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

```
Connected to 10.31.101.100.
220 Welcome to FortiGate FTP proxy
Name (10.31.101.100:user):
```

You can change the message by editing the FTP Explicit Banner Message replacement message.

3. At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

```
<proxy-user>:<proxy-password>:<server-user>@<server-address>
```

For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

```
p-name:p-pass:s-name@ftp.example.com
```

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4. The FTP proxy forwards the connection request, including the user name, to the FTP server.
5. If the user name is valid for the FTP server it responds with a password request prompt.
6. The FTP proxy relays the password request to the FTP client.
7. The user enters the FTP server password and the client sends the password to the FTP proxy.
8. The FTP proxy relays the password to the FTP server.
9. The FTP server sends a login successful message to the FTP proxy.
10. The FTP proxy relays the login successful message to the FTP client.
11. The FTP client starts the FTP session.

All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

Explicit FTP proxy session

From a simple command line FTP client connecting to an the previous sequence could appear as follows:

```
ftp 10.31.101.100 21
Connected to 10.31.101.100.
220 Welcome to FortiGate FTP proxy
Name (10.31.101.100:user): p-name:p-pass:s-name@ftp.example.com
331 Please specify the password.
Password: s-pass
230 Login successful.
Remote system type is UNIX
Using binary mode to transfer files.
ftp>
```

Security profiles, threat weight, device identification, and the explicit FTP proxy

You can apply antivirus, data leak prevention (DLP), and SSL/SSH inspection to explicit FTP proxy sessions. Security profiles are applied by selecting them in an explicit FTP proxy policy or an authentication rule in an FTP proxy security policy.

Traffic accepted by explicit FTP proxy policies contributes to threat weight data.

The explicit FTP proxy is not compatible with device identification.

Explicit FTP proxy options and SSL/SSH inspection

Since the traffic accepted by the explicit FTP proxy is known to be FTP and since the ports are already known by the proxy, the explicit FTP proxy does not use the FTP port proxy options settings.

When adding UTM features to an FTP proxy security policy, you must select a proxy options profile. In most cases you can select the default proxy options profile. You could also create a custom proxy options profile.

The explicit FTP proxy supports the following proxy options:

- Block Oversized File and oversized file limit

The explicit FTP proxy does not support the following protocol options:

- Client comforting

Explicit FTP proxy sessions and antivirus

For explicit FTP proxy sessions, the FortiGate unit applies antivirus scanning to FTP file GET and PUT requests. The FortiGate unit starts virus scanning a file in an FTP session when it receives a file in the body of an FTP request.

Flow-based virus scanning is not available for explicit FTP proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit FTP proxy sessions use the regular virus database.

Explicit FTP proxy sessions and user limits

FTP clients do not open large numbers of sessions with the explicit FTP proxy. Most sessions stay open for a short while depending on how long a user is connected to an FTP server and how large the file uploads or downloads are. So unless you have large numbers of FTP users, the explicit FTP proxy should not be adding large numbers of sessions to the session table.

Explicit FTP proxy sessions and user limits are combined with explicit web proxy session and user limits. For information about explicit proxy session and user limits, see .

FTP Proxy Configuration

General explicit FTP proxy configuration steps

You can use the following general steps to configure the explicit FTP proxy.

To enable the explicit FTP proxy - web-based manager:

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options**. Select **Enable Explicit FTP Proxy** to turn on the explicit FTP proxy.
2. Select **Apply**.

The **Default Firewall Policy Action** is set to **Deny** and requires you to add a explicit FTP proxy policy to allow access to the explicit FTP proxy. This configuration is recommended and is a best practice because you can use policies to control access to the explicit FTP proxy and also apply security features and authentication.

3. Go to **Network > Interfaces** and select one or more interfaces for which to enable the explicit web proxy. Edit the interface and select **Enable Explicit FTP Proxy**.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4. Go to **Policy & Objects > Proxy Policy** and select **Create New** and set the **Explicit Proxy Type** to **FTP**.

You can add multiple explicit FTP proxy policies.

5. Configure the policy as required to accept the traffic that you want to be processed by the explicit FTP proxy.

The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to **Any**.

The destination address of the policy should match the IP addresses of FTP servers that clients are connecting to. The destination address could be **all** to allow connections to any FTP server.

If **Default Firewall Policy Action** is set to Deny, traffic sent to the explicit FTP proxy that is not accepted by an explicit FTP proxy policy is dropped. If **Default Firewall Policy Action** is set to Allow then all FTP proxy sessions that don't match a policy are allowed.

For example the following explicit FTP proxy policy allows users on an internal network to access FTP servers on the Internet through the wan1 interface of a FortiGate unit.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT

The following explicit FTP proxy policy requires users on an internal network to authenticate with the FortiGate unit before accessing FTP servers on the Internet through the wan1 interface.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

6. Select **Create New** to add an **Authentication Rule** and configure the rule as follows:

Groups	Proxy-Group
Source Users	(optional)
Schedule	always

7. Add security profiles as required and select **OK**.
8. You can add multiple authentication rules to apply different authentication for different user groups and users and also apply different security profiles and logging settings for different users.
9. Select **OK**.

To enable the explicit FTP proxy - CLI:

1. Enter the following command to turn on the explicit FTP proxy. This command also changes the explicit FTP proxy port to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
end
```

The default explicit FTP proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit FTP proxy.

2. Enter the following command to enable the explicit FTP proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit FTP proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

The source address for a ftp-proxy security policy cannot be assigned to a FortiGate unit interface.

4. Use the following command to add an explicit FTP proxy policy that allows all users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
  edit 0
    set proxy ftp
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
  end
```

5. Use the following command to add an explicit FTP proxy policy that allows authenticated users on the internal subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet.

```
config firewall proxy-policy
edit 0
    set proxy ftp
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr Fortinet-web-sites
    set action accept
    set schedule always
    set groups <User group>
end
end
```

Restricting the IP address of the explicit FTP proxy

You can use the following command to restrict access to the explicit FTP proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require users to connect to the IP address 10.31.101.100 to connect to the explicit FTP proxy:

```
config ftp-proxy explicit
    set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit FTP proxy

You can use the following command to restrict the source address of outgoing FTP proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config ftp-proxy explicit
    set outgoing-ip 172.20.120.100
end
```

Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning

This example describes how to configure the explicit FTP proxy for the example network shown below. In this example, users on the internal network connect to the explicit FTP proxy through the Internal interface with IP address 10.31.101.100. The explicit web proxy is configured to use port 2121 so to connect to an FTP server on the Internet users must first connect to the explicit FTP proxy using IP address 10.31.101.100 and port 2121.

Example explicit FTP proxy network topology

In this example, explicit FTP proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit FTP proxy traffic includes an identity based policy that applies per session authentication to explicit FTP proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies UTM virus scanning and DLP.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit FTP proxy and change the FTP port to 2121.
2. Enable the explicit FTP proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit FTP proxy.
4. Add a user identity security policy for the explicit FTP proxy.
5. Enable antivirus and DLP features for the identity-based policy.

Configuring the explicit FTP proxy - web-based manager

Use the following steps to configure the explicit FTP proxy from FortiGate web-based manager.

To enable and configure the explicit FTP proxy

1. Go to **Network > Explicit Proxy > Explicit FTP Proxy Options** and change the following settings:

Enable Explicit FTP Proxy	Select.
Listen on Interface	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
FTP Port	2121
Default Firewall Policy Action	Deny

2. Select **Apply**.

To enable the explicit FTP proxy on the Internal interface

1. Go to **Network > Interfaces**, edit the Internal interface and select **Enable Explicit FTP Proxy**.

To add a RADIUS server and user group for the explicit FTP proxy

1. Go to **User & Device > RADIUS Servers**.
2. Select **Create New** to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3. Go to **User > User > User Groups** and select **Create New**.

Name	Explicit_proxy_user_group
Type	Firewall

Remote groups	RADIUS_1
Group Name	ANY

4. Select **OK**.

To add a security policy for the explicit FTP proxy

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet
Subnet / IP Range	10.31.101.0
Interface	Any

3. Go to **Policy & Objects > Proxy Policy** and select **Create New**.
4. Configure the explicit FTP proxy security policy.

Explicit Proxy Type	FTP
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Action	AUTHENTICATE

5. Under **Configure Authentication Rules** select **Create New** to add an authentication rule:

Groups	Explicit_policy
Users	Leave blank
Schedule	always

6. Turn on **Antivirus** and **Web Filter** and select the **default** profiles for both.
7. Select the **default** proxy options profile.
8. Select **OK**.
9. Make sure **Enable IP Based Authentication** is not selected and **Default Authentication Method** is set to **Basic**.
10. Select **OK**.

Configuring the explicit FTP proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable and configure the explicit FTP proxy

1. Enter the following command to enable the explicit FTP proxy and set the TCP port that proxy accepts FTP connections on to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
  set sec-default-action deny
end
```

To enable the explicit FTP proxy on the Internal interface

1. Enter the following command to enable the explicit FTP proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
```

To add a RADIUS server and user group for the explicit FTP proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
  edit RADIUS_1
    set server 10.31.101.200
    set secret RADIUS_server_secret
  end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
  end
```

To add a security policy for the explicit FTP proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

2. Enter the following command to add the explicit FTP proxy security policy:

```
config firewall proxy-policy
  edit 0
    set proxy ftp
    set dstintf wan1
    set srcaddr Internal_subnet
    set dstaddr all
    set action accept
    set identity-based enable
    set ipbased disable
    set active-auth-method basic
```

```
set groups <User group>
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit FTP proxy configuration is working as expected. These steps use a command line FTP client.

To test the explicit web proxy configuration

1. From a system on the internal network start an FTP client and enter the following command to connect to the FTP proxy:

```
ftp 10.31.101.100
```

The explicit FTP proxy should respond with a message similar to the following:

```
Connected to 10.31.101.100.
220 Welcome to Floodgate FTP proxy
Name (10.31.101.100:user):
```

2. At the prompt enter a valid username and password for the RADIUS server followed by a user name for an FTP server on the Internet and the address of the FTP server. For example, if a valid username and password on the RADIUS server is `ex_name` and `ex_pass` and you attempt to connect to an FTP server at `ftp.example.com` with user name `s_name`, enter the following at the prompt:

```
Name (10.31.101.100:user):ex_name:ex_pass:s_name@ftp.example.com
```

3. You should be prompted for the password for the account on the FTP server.
4. Enter the password and you should be able to connect to the FTP server.
5. Attempt to explore the FTP server file system and download or upload files.
6. To test UTM functionality, attempt to upload or download an ECAR test file. Or upload or download a text file containing text that would be matched by the DLP sensor.

For eicar test files, go to <http://eicar.org>.

Diagnose commands for WAN Optimization

The following get and diagnose commands are available for troubleshooting WAN optimization, web cache, explicit proxy and WCCP.

get test {wad | wccpd} <test_level>

Display usage information about WAN optimization, explicit proxy, web cache, and WCCP applications. Use `<test_level>` to display different information.

```
get test wad <test_level>
get test wccpd <test_level>
```

Variable	Description
wad	Display information about WAN optimization, web caching, the explicit web proxy, and the explicit FTP proxy.

Variable	Description
wccpd	Display information about the WCCP application.

Examples

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 1
WAD manager process status: pid=113 n_workers=1 ndebug_workers=0
```

Enter the following command to display all test options:

```
get test wad

WAD process 82 test usage:
 1: display process status
 2: display total memory usage.
 99: restart all WAD processes
1000: List all WAD processes.
1001: display debug level name and values
1002: display status of WANOpt storages
1068: Enable debug for all WAD workers.
1069: Disable debug for all WAD workers.
2yxx: Set No. xx process of type y as diagnosis process.
 3: display all fix-sized advanced memory stats
 4: display all fix-sized advanced memory stats in details
500000..599999: cmem bucket stats (599999 for usage)
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
 60: show debug stats.
 61: discard all wad debug info that is currently pending
62xxx: set xxxM maximum output buffer size for WAD debug. 0, set back to default.
 68: Enable process debug
 69: Disable process debug
 98: gracefully stopping WAD process
 9xx: Set xx workers(0: default based on user configuration.)
```

diagnose wad

Display diagnostic information about the WAN optimization daemon (wad).

```
diagnose wad console-log {disable | enable}
diagnose wad debug-url {disable | enable}
diagnose wad filter {clear | dport | dst | list | negate | protocol | sport | src | vd}
diagnose wad history {clear | list}
diagnose wad session {clear | list}
diagnose wad stats {cache | cifs | clear | crypto | ftp | http | list | mapi | mem |
  scan | scripts | summary | tcp | tunnel}
diagnose wad user {clear | list}
diagnose wad tunnel {clear | list}1
diagnose wad webcache {clear | list} {10min | hour | day | 30days}
```

Variable	Description
<code>console-log</code>	Enable or disable displaying WAN optimization log messages on the CLI console.
<code>filter</code>	<p>Set a filter for listing WAN optimization daemon sessions or tunnels.</p> <p><code>clear</code> reset or clear the current log filter settings.</p> <p><code>dport</code> enter the destination port range to filter by.</p> <p><code>dst</code> enter the destination address range to filter by.</p> <p><code>list</code> display the current log filter settings</p>
<code>history</code>	Display statistics for one or more WAN optimization protocols for a specified period of time (the last 10 minutes, hour, day or 30 days).
<code>session</code>	Display diagnostics for WAN optimization sessions or clear active sessions.
<code>stats</code>	Display statistics for various parts of WAN optimization such as cache statistics, CIFS statistics, MAPI statistics, HTTP statistics, tunnel statistics etc. You can also clear WAN optimization statistics and display a summary.
<code>tunnel</code>	Display diagnostic information for one or all active WAN optimization tunnels. Clear all active tunnels. Clear all active tunnels.
<code>webcache</code>	Display web cache activity for the specified time period.

Example diagnose wad tunnel list

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=100 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=99 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=98 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=98 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
```

```
bytes_in=348 bytes_out=384

Tunnel: id=39 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=39 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1068 bytes_out=1104

Tunnel: id=7 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=7 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=8 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=8 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=5 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=5 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=4 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=4 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=1 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=1 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnel: id=2 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web_servers id=2 ip=172.20.120.141
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example diagnose wad webcache list

This following command displays the web caching stats for the last 10 minutes of activity. The information displayed is divided into 20 slots and each slot contains stats for 30 seconds:

20 * 30 seconds = 600 seconds = 10 minutes

```
diagnose wad webcache list 10min
web cache history vd=0 period=last 10min
```

The first 20 slots are for HTTP requests in the last 10 minutes. Each slot of stats has four numbers, which is the total number of HTTP requests, the number of cacheable HTTP requests, the number of HTTP requests that are processed by the web cache (hits), and the number of HTTP requests that are processed without checking the web cache (bypass). There are many reasons that a HTTP request may bypass web cache.

total	cacheable	hits	bypass
-----	-----	-----	-----
36	10	3	1
128	92	1	10
168	97	2	3
79	56	0	3
106	64	5	3
180	118	6	11
88	53	7	3
80	43	4	4
107	44	9	2
84	12	0	2
228	139	52	10
32	2	0	5
191	88	13	7
135	25	40	3
48	10	0	8
193	13	7	7
67	31	1	2
109	35	24	6
117	36	10	5
22	0	0	4

The following slots are for video requests in the last 10 minutes. Each slot has two numbers for each 30 seconds: total number of video requests, and the number of video requests that are processing using cached data.

video total	video hit
-----	-----
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0
0	0

The following 20 slots are for traffic details in last 10 minutes. Each slot has four numbers for 30 seconds each.

--- LAN ---		--- WAN ---	
bytes_in	bytes_out	bytes_in	bytes_out
-----	-----	-----	-----
34360	150261	141086	32347
105408	861863	858501	100670
128359	1365919	1411849	127341
60103	602813	818075	59967
105867	1213192	1463736	97489
154961	1434784	1344911	158667
73967	370275	369847	70626
129327	602834	592399	123676
115719	663446	799445	111262
58151	724993	631721	59989
175681	2092925	1092556	166212
37805	33042	41528	37779
183686	1255118	1114646	172371
106125	904178	807152	81520
66147	473983	543507	66782
170451	1289530	1201639	165540

134142	579605	821430	132113
96895	668037	730633	89872
59576	248734	164002	59448

diagnose wacs

Display diagnostic information for the web cache database daemon (wacs).

```
diagnose wacs clear
diagnose wacs reents
diagnose wacs restart
diagnose wacs stats
```

Variable	Description
clear	Remove all entries from the web cache database.
recents	Display recent web cache database activity.
restart	Restart the web cache daemon and reset statistics.
stats	Display web cache statistics.

diagnose wadbd

Display diagnostic information for the WAN optimization database daemon (wadbd).

```
diagnose wadbd {check | clear | recents | restart | stats}
```

Variable	Description
check	Check WAN optimization database integrity.
clear	Remove all entries from the WAN optimization database.
recents	Display recent WAN optimization database activity.
restart	Restart the WAN optimization daemon and reset statistics.
stats	Display WAN optimization statistics.

diagnose debug application {wad | wccpd} [<debug_level>]

View or set the debug level for displaying WAN optimization and web cache-related daemon debug messages. Include a <debug_level> to change the debug level. Leave the <debug_level> out to display the current debug level. Default debug level is 0.

```
diagnose debug application wad [<debug_level>]
diagnose debug application wccpd [<debug_level>]
```

Variable	Description
wad	Set the debug level for the WAN optimization daemon.
wccpd	Set the debug level for the WCCP daemon.

diagnose test application wad 2200

The debug level 2200 switches the debug to explicit proxy mode. You have to enter this debug level first. After that you have to type the command again with a different debug level to check the different explicit proxy

statistics. To list what each debug level shows, follow these steps in any FortiGate device:

1. Enable explicit proxy globally and in one interface, to start the wad process. If the wad process is *not* running, you *cannot* list the options.
2. Once the wad process starts, type:

```
diagnose test application wad 2200
diagnose test application wad //// Do not type any debug level value to list all the options.
```

This is the output you will get:

```
# diagnose test application wad 2200
Set diagnosis process: type=wanopt index=0 pid=114
# diagnose test application wad
WAD process 114 test usage:
1: display process status
2: display total memory usage
99: restart all WAD processes
1000: List all WAD processes
1001: display debug level name and values
1002: display status of WANOpt storages
1068: Enable debug for all WAD workers
1069: Disable debug for all WAD workers
2yxx: Set No. xx process of type y as diagnosis process
3: display all fix-sized advanced memory stats
4: display all fix-sized advanced memory stats in details
500000..599999: cmem bucket stats (599999 for usage)
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help & usage)
60: show debug stats
61: discard all wad debug info that is currently pending
62xxx: set xxxM maximum output buffer size for WAD debug (0: set back to default)
68: Enable process debug
69: Disable process debug
98: gracefully stopping WAD process
20: display all listeners
21: display TCP port info
22: display SSL stats
23: flush SSL stats
24: display SSL mem stats
70: display av memory usage
71xxxx: set xxxMiB maximum AV memory (0: set back to default)
72: toggle av memory protection
73: toggle AV conserve mode (for debug purpose)
90: set to test disk failure
91: unset to test disk failure
92: trigger a disk failure event
100: display explicit proxy settings
101: display firewall policies
102: display security profile mapping for regular firewall policy
103: display Web proxy forwarding server and group
104: display DNS stats
105: display proxy redirection scan stats
106: list all used fqdns
107: list all firewall address
110: display current web proxy users
```

```
111: flush current web proxy users
112: display current web proxy user summary
113: display WAD fsso state
114: display HTTP digest stats
115: display URL patterns list of cache exemption or forward server
116: toggle dumping URL when daemon crashes
120: display Web Cache stats
121: flush Web Cache stats
122: flush idle Web cache objects
123: display web cache cache sessions
130: display ftpproxy stats
131: clear ftpproxy stats
132: list all current ftpproxy sessions
133: display all catched webfilter profiles
200: display WANopt profiles
201: display all peers
202: display video cache rules (patterns)
203: display all ssl servers
210: toggle disk-based byte-cache
211: toggle memory-based byte-cache
212: toggle cifs read-ahead
221: display tunnel protocol stats
222: flush tunnel protocol stats
223: display http protocol stats
224: flush http protocol stats
225: display cifs protocol stats
226: flush cifs protocol stats
227: display ftp protocol stats
228: flush ftp protocol stats
229: display mapi protocol stats
230: flush mapi protocol stats
231: display tcp protocol stats
232: flush tcp protocol stats
233: display all protocols stats
234: flush all protocols stats
240: display WAD tunnel stats
241: display tunnel compressor state
242: flush tunnel compressor stats
243: display Byte Cache DB state
244: flush Byte Cache DB stats
245: display Web Cache DB state
246: flush Web Cache DB stats
247: display cache state
248: flush cache stats
249: display memory cache state
250: flush memory cache stats
261yxxx: set xxx concurrent Web Cache session for object storage y
262yxxx: set xxxK(32K, 64K,...) unconfirmed write/read size per Web Cache object for
        object storage y
263yxxxx: set xxxxK maximum ouput buffer size for object storage y
264yxxx: set lookup lowmark (only if more to define busy status) to be xx for object
        storage y
265yxxx: set xxxK maximum ouput buffer size for byte storage y
266yxxx: set number of buffered add requests to be xxx for byte storage y
267yxxxx: set number of buffered query requests to be xxxx for byte storage y
268yxxxxx: set number of concurrent query requests to be xxxxx for byte storage y
```

Chapter 10 - FortiView

FortiView

This document provides a general guide to FortiView, the FortiOS log view tool, explaining its layout, features, and its usefulness in everyday administrative scenarios. This document includes:

- [Overview on page 1257](#) outlines the role FortiView plays in FortiOS and its overall layout. This section also identifies which FortiGate platforms support the full FortiView features.
- [FortiView consoles on page 1268](#) describes the various FortiView consoles available in FortiOS, including example scenarios, in most cases.
- [Reference on page 1285](#) explains reference information for the various consoles in FortiView, and describes the assortment of filtering options, drilldown options, and columns available.
- [Troubleshooting FortiView on page 1298](#) offers solutions to common technical issues experienced by FortiGate users regarding FortiView.

Purpose

FortiView is a comprehensive monitoring system for your network that integrates real-time and historical data into a single view on your FortiGate. It can log and monitor threats to networks, filter data on multiple levels, keep track of administrative activity, and more.

FortiView allows you to use multiple filters within the consoles, enabling you to narrow your view to a specific time (up to 24 hours in the past), by user ID or local IP address, by application, and many more. For more on FortiView's filtering options, see [Filtering options on page 1286](#)

FortiView can be used to investigate traffic activity, such as user uploads/downloads or videos watched on YouTube, on a network-wide, user group, and individual-user level, with information relayed in both text and visual format. FortiView makes it easy to get an actionable picture of your network's internet activity.

The degree to which information can be logged will depend on which FortiGate unit you have. For more information, see [Enabling FortiView on page 1258](#).

What's new in FortiOS 5.6

The following section describes new FortiView features added to FortiOS 5.6.0, 5.6.1, 5.6.3, 5.6.4.

FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

Increased visibility of interactivity in FortiView

Visual feedback has been added to mouse-over on FortiView charts, in order to increase visibility of interactivity that already existed. Cursors have also been updated to display possible interactions.

Automatic synchronization of log display location

In previous versions, log display location could differ between Log & Report and FortiView, which could result in empty log screens if the two were not synchronized. As of 5.6.4, both log viewers automatically pick the best available log device. A different log device can be manually selected.

As a result, the associated CLI command `log gui-display location` has been removed.

FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

Support learning reports and FortiAnalyzer (415806)

Both backend and GUI have been updated to support learning reports from FortiAnalyzer.

Backend updates the query configure list; GUI updates learning report to use log display device setting.

Added support to FortiView to sort by application risk and browsing time (249666)

Added ability to sort applications by threat level and by browsing time so that admin can quickly see and prioritize the riskier applications at the top of the list.

FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

FortiView Dashboard Widget (434179)

A new widget type has been added to the FortiGate Dashboard, that displays compact FortiView data. Supported FortiViews include Source, Destination, Application, Country, Interfaces, Policy, Wifi Client, Traffic Shaper, Endpoint Vulnerability, Cloud User, Threats, VPN, Websites, Admin, and System. All usual visualizations are supported.

Widgets can be saved directly to the Dashboard from a filtered page in FortiView, or configured in the CLI.

Interface Categories (srcintfrole, etc) added to log data (434188)

In 5.6, logs and FortiView both sort log traffic into two interface categories: "Traffic from LAN/DMZ", and "Traffic from WAN." For greater compatibility and troubleshooting of FortiAnalyzer and FortiCloud setups, interface category fields that expose this information have been added to general log data in 5.6.1: `srcintfrole` and `dstintfrole` for better backend control and monitoring.

FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

Added Vulnerability score topology view (303786)

In **Physical Topology** and **Logical Topology** pages, there are two new views added: **Vulnerability**, and **Threat**. Drill-downs in these menus will now include Vulnerability/Threat information. In Vulnerability view, device bubbles are colored based on maximum vulnerability level, and bubble size is the vulnerability score. In Threat view, device bubbles are colored based on maximum threat level, and bubble size is the threat score.

FortiView VPN tunnel map feature (382767)

The FortiView VPN page now displays VPN tunnel connections between devices, and offers more information about tunnels and devices on drill-down.

Updated FortiView CSF topology pages (384188)

The FortiView **Physical Topology** and **Logical Topology** pages have been updated in 5.6.0 to reorganize and clarify larger deployments with servers and multi-directional traffic.

Historical FortiView includes FortiAnalyzer (387423)

Data from associated FortiAnalyzer devices can now be selected as a log display option for Historical FortiView.

FortiView menu reorganization (399713)

The order of FortiView pages has been reorganized in 5.6.0 based on the source interface of data being displayed:

- Topology
- Traffic from LAN/DMZ
- Traffic from WAN
- All Segments

Data Exchange with FortiAnalyzer (393891)

Rather than sending all CSF information via log messages, FortiGate and FortiAnalyzer will now directly pass CSF information (tree, interface roles, user devices, HA members), if the FAZ responds to notices that are sent when the data has changed.

Google Maps Integration

FortiView now uses Google Maps to display location-related information. In this release the first view to use Google maps this component is the FortView VPN page. All current VPNs can be viewed on a fully scalable Google world map.

FortiView usability and organization updates (306247)

Several organization changes have been made to make the FortiView menu order less cluttered, and more intuitive.

- **WiFi Client Monitor** is now in FortiView, but is hidden when there is no managed FortiAP or WiFi Radio.
- **Country** view has been merged into **Destinations** view.
- **Failed Authentication** and **Admin Login** views have been merged into **System Events** view.

Overview

This section provides an overview of FortiView, its interface, and options, including the following:

Enabling FortiView

By default, FortiView is enabled on FortiGate running FortiOS firmware version 5.2 and above. You will find the FortiView consoles in the main menu. However, certain options will not appear unless the FortiGate has **Disk Logging** enabled.

Only certain FortiGate models support Disk Logging. A complete list of FortiGate platforms that support Disk Logging is provided in the matrix below.

To enable Disk Logging

1. Go to **Log & Report > Log Settings** and select the checkbox next to **Disk**.
2. **Apply** the change.

To enable Disk Logging - CLI

```
config log disk setting
    set status enable
end
```

FortiView Feature Support - Platform Matrix

Note that the following table identifies three separate aspects of FortiView in FortiOS 5.2.3:

- [Basic feature support](#)
- [Historical Data](#)
- [Disk Logging](#)

Platform	Basic Feature Support	Disk Logging	Historical Data *
FG/FWF-20C Series	✓		
FG/FWF-30D/40C Series	✓		
FG/FWF-60C Series	✓		
FG/FWF-60D Series	✓		
FGR-60D	✓		
FG-60D	✓		
FG/FWF-80C Series	✓		
FG-80D	✓	✓	1 hour
FG/FWF-90D Series	✓	✓	1 hour
FG/FWF-92D Series	✓		

Platform	Basic Feature Support	Disk Logging	Historical Data *

✓ = Default support.

= Local storage required.

* Refer to section on Historical Data below.

Basic feature support

FortiView's consoles give insight into your user's traffic, not merely showing which users are creating the most traffic, but what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network.

FortiView basic feature support consists of the following consoles:

- [Sources](#)
- [Destinations](#)
- [Interfaces](#)
- [Policies](#)
- [All Sessions](#)
- [Applications](#)

The complete array of features in FortiView requires disk logging enabled (see below). It includes those consoles listed above as well as the following:

- [WiFi Clients](#)
- [Cloud Applications](#)
- [Web Sites](#)
- [Threats](#)
- [VPN](#)

Historical Data

Not all consoles have the same available historical data options, depending on whether or not your traffic is locally stored.

Below is a table showing which features are available for units using local storage, including the historical data options.

Only FortiGate models 100D and above support the 24 hour historical data.

Features	With Local Storage				Without Local Storage			
	Now	5 min	1 hr	24 hr *	Now	5 min	1 hr	24 hr
Sources	✓	✓	✓	✓	✓			
Destinations	✓	✓	✓	✓	✓			
Interfaces	✓	✓	✓	✓				
Policies	✓	✓	✓	✓				
All Sessions	✓	✓	✓	✓	✓			
Applications	✓	✓	✓	✓	✓			
WiFi Clients		✓	✓	✓				
Cloud Applications	✓	✓	✓	✓	✓			
Web Sites	✓	✓	✓	✓				
Threats		✓	✓	✓				
Threat Map	✓				✓			
FortiSandbox		✓	✓	✓				
System Events		✓	✓	✓				
VPN		✓	✓	✓				

* Not available for desktop models with SSD.

7-day time display

As mentioned previously, certain models support 7-day time display. These models are listed below:

- FortiGate 1000D
- FortiGate 1500D
- FortiGate 3700DX
- FortiGate 3700D

The option for 7-day time display, however, can only be configured in the CLI using the following command:

```
config log setting
    set fortiview-weekly-data {enable|disable}
end
```

Disk Logging

Only certain FortiGate models support Disk Logging (see above).

To enable Disk Logging, go to **Log & Report > Log Settings**, and select the checkbox next to **Disk** and apply the change. Some devices will require disk logging to be enabled in the CLI, using the following command:

```
config log disk setting
    set status enable
end
```

Configuration Dependencies

Most FortiView consoles require the user to enable several features to produce data. The following table summarizes the dependencies:

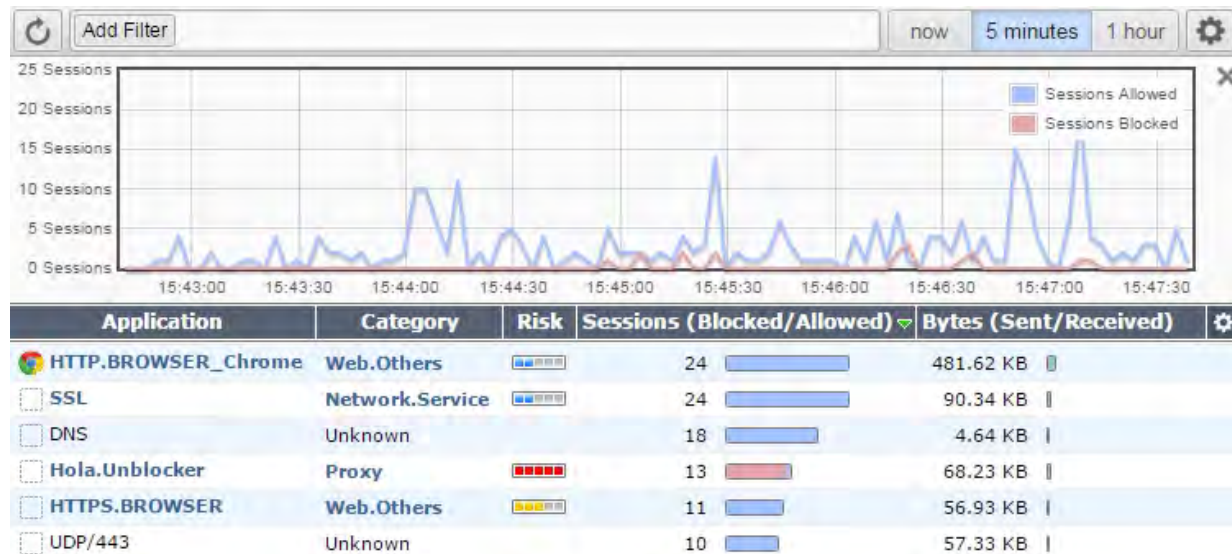

Feature	Dependencies (Realtime)	Dependencies (Historical)
Sources	None, always supported	Traffic logging enabled in policy
Destinations	None, always supported	Traffic logging enabled in policy
Interfaces	None, always supported	Disk logging enabled
		Traffic logging enabled in policy
Policies	None, always supported	Disk logging enabled
		Traffic logging enabled in policy
All Sessions	None, always supported	Traffic logging enabled in policy
Applications	None, always supported	Disk logging enabled
		Traffic logging enabled in policy
		Application control enabled in policy
WiFi Clients	SSID must be in Tunnel mode	Disk logging enabled
		Traffic logging enabled in policy
		SSID must be in Tunnel mode

Feature	Dependencies (Realtime)	Dependencies (Historical)
Cloud Applications	Not supported	Disk logging enabled Application control enabled in policy SSL "deep inspection" enabled in policy Deep application inspection enabled in application sensor Extended UTM log enabled in application sensor
Web Sites	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile
Threats	Not supported	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled
Threat Map	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled
FortiSandbox	Not supported	Disk logging enabled Traffic logging enabled in policy
System Events	Not supported	Disk logging enabled
VPN	Not supported	Disk logging enabled Traffic logging enabled in policy

FortiView interface

FortiView lets you access information about the traffic activity on your FortiGate, visually and textually. FortiView is broken up into several consoles, each of which features a top menu bar and a graph window, as seen in the following image:

FortiView Application console sorted by Sessions (Blocked/Allowed)

The top menu bar features:

- a **Refresh** button, which updates the data displayed,
- a **Filter** button, for filtering the data by category,
- a **Settings** button (containing additional viewing settings and a link to the Threat Weight menu).
- a drop-down menu of different views:
 - **Time Display** (options: now, 5 minutes, 1 hour, or 24 hours),
 - **Table View**
 - **Timeline View**
 - **Bubble Chart**¹
 - **Country Map**

¹ For information on the Bubble Chart, refer to [Bubble Chart Visualization on page 1265](#).

Certain views are only available in specific consoles.

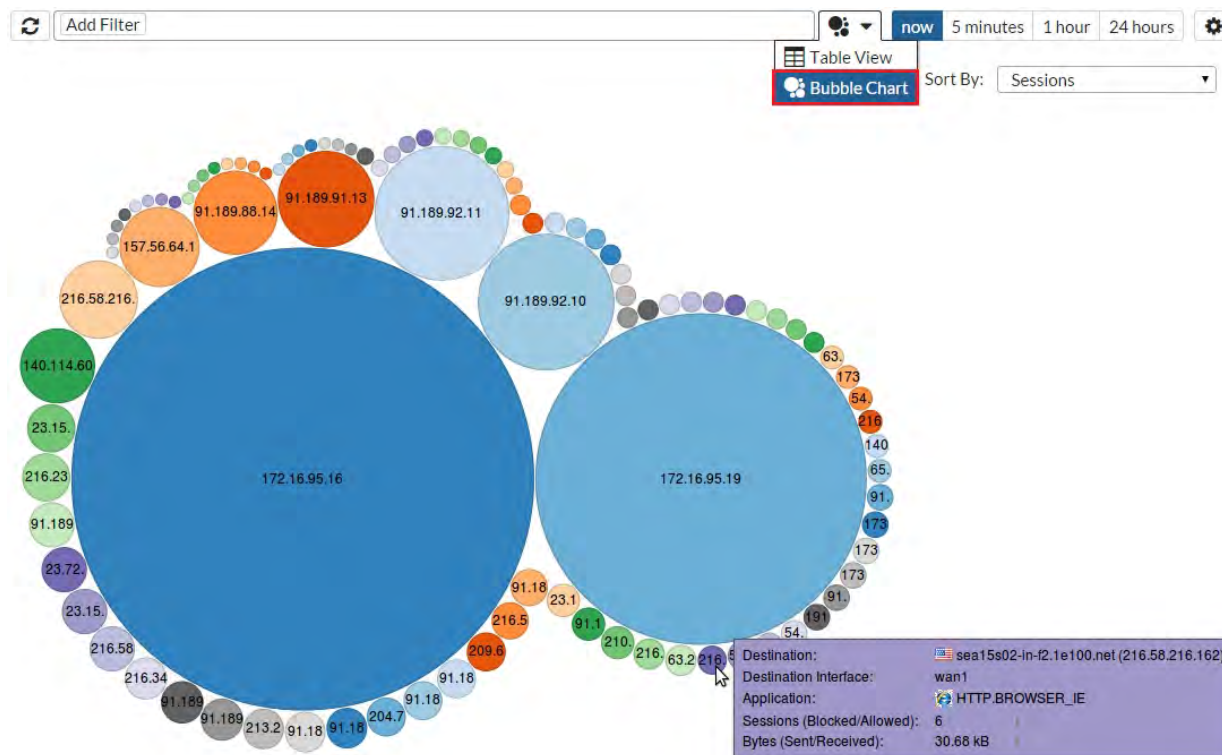

The FortiView graph

The graph window can be hidden using the **X** in the top right corner, and re-added by selecting **Show Graph**. To zoom in on a particular section of the graph, click and drag from one end of the desired section to the other. This will appear in the **Time Display** options as a **Custom** selection. The minimum selection size is 60 seconds.

Only FortiGate models 100D and above support the 24 hour historical data.

Bubble Chart Visualization

Notes about the Bubble Chart:

- It is possible to sort on the Bubble Chart using the **Sort By:** dropdown menu.
- The size of each bubble represents the related amount of data.
- Place your cursor over a bubble to display a tool-tip with detailed info on that item.
- You can click on a bubble to drilldown into greater (filtered) detail.

Links created between FortiView and View/Create Policy

The **Policy** column in FortiView consoles and the Log Viewer pages includes a link, which navigates to the IPv4 or IPv6 policy list and highlights the policy.

Right-clicking on a row in FortiView or the Log Viewer has menu items for **Block Source**, **Block Destination** and **Quarantine Source** where appropriate columns are available to determine these values. When multiple rows are selected, the user will be prompted to create a named **Address Group** to contain the new addresses.

When the user clicks **Block Source** or **Block Destination** they are taken to a policy creation page with enough information filled in to create a policy blocking the requested IP traffic.

The policy page will feature an informational message block at the top describing the actions that will be taken. Once the user submits the form, the requisite addresses, groups and policy will be created at once.

If the user clicks on **Quarantine User** then they will be prompted for a duration. They may also check a box for a **Permanent Ban**. The user can manage quarantined users under **Monitor > Quarantine Monitor**.

Visualization support for the Admin Logins page

A useful chart is generated for Admin login events under **FortiView > Admin Logins**. You can view the information in either **Table View** or **Timeline View** (shown below). In Timeline View, each line represents an administrator, with individual sessions indicated per administrator line. When you hover over a particular timeline, detailed information appears in a tooltip.

Realtime visualization

To enable realtime visualization:

1. Click on the **Settings** icon next to the upper right-hand corner and select **Auto update realtime visualizations**. An option is displayed to set the **Interval (seconds)**. The maximum value is 300.
2. Enter a desired **Interval** and click **Apply**.

Accelerated sessions

When viewing sessions in the [All Sessions](#) console, information pertaining to NP4/ NP6 acceleration is now reflected via an appropriate icon in the table. The tooltip for the icon includes the NP chip type and its total number of accelerated sessions.

Filtering on accelerated sessions

You can filter the console on 'FortiASIC' ('Accelerated' versus 'Not Accelerated') sessions.

WHOIS Lookup anchor for public IPv4 addresses

A Reverse IP lookup is possible using the WHOIS lookup icon available when you mouse over a public IP address in a FortiView log. If you left-click on the lookup icon, a new tab is opened in your browser for www.networksolutions.com, and a lookup is performed on the selected IP address (this option persists after drilling down one level in FortiView).

FortiView consoles

This section describes the following log filter consoles available in FortiView:

- [Sources on page 1269](#) displays detailed information on the sources of traffic passing through the FortiGate, and the section covers how you can investigate an unusual spike in traffic to determine which user is responsible.
- [Destinations on page 1270](#) displays detailed information on user destination-accessing through the use of drill down functionality.
- [Applications on page 1271](#) displays Applications used on the network that have been recognized by Application Control, and this section shows how you can view what sort of applications individual employees are using.
- [Cloud Applications on page 1272](#) displays Web/Cloud Applications used on the network, and this section shows how you can drill down to access detailed data on cloud application usage, e.g. YouTube.
- [Web Sites on page 1273](#) displays websites visited as part of network traffic that have been recognized by Web Filtering, and this section shows how you can investigate instances of proxy avoidance, which is the act of circumventing blocks using proxies.
- [Threats on page 1274](#) monitors threats to the network, both in terms of their Threat Score and Threat Level.
- [WiFi Clients on page 1275](#) displays a list of all the devices connected to the WLAN.
- ["Traffic Shaping" on page 1276](#) displays a list of existing Traffic Shapers, detailing their bandwidth use and which traffic is being shaped by each shaper.
- [System Events on page 1277](#) displays security events detected by FortiOS, providing a name and description for the events, an assessment of the event's severity level, and the number of instances the events were detected.
- [VPN on page 1278](#) displays how users can access information on any VPNs associated with their FortiGate.
- ["Endpoint Vulnerability" on page 1279](#) displays a list of Vulnerability events detected by the FortiGate on networked devices, along with links to further vulnerability information and databases.
- [Threat Map on page 1280](#) provides a geographical display of threats, in realtime, from international sources as they arrive at your FortiGate.
- [Policies on page 1281](#) displays what policies are in affect on your network, what their source and destination interfaces are, how many sessions are in each policy, and what sort of traffic is occurring.
- [Interfaces on page 1282](#) displays the number of interfaces connected to your network, how many sessions there are in each interface, and what sort of traffic is occurring.
- [FortiSandbox on page 1283](#) displays FortiSandbox activity. FortiSandbox detects and analyzes advanced attacks designed to bypass traditional security defenses, and has a wide array of features that allow it to prevent future attacks from occurring again.
- [All Sessions on page 1284](#) displays complete information on all FortiGate sessions, with the ability to filter sessions by port number and application type.

Sources

The **Sources** console provides information about the sources of traffic on your FortiGate unit.

This console can be filtered by Country, Destination Interface, Policy, Result, Source, and Source Interface. For more on filters, see [Filtering options](#).

Specific devices and time periods can be selected and drilled down for deep inspection.

Scenario: Investigating a spike in traffic

A system administrator notices a spike in traffic and wants to investigate it. From the **Sources** window, they can determine which user is responsible for the spike by following these steps:

1. Go to **FortiView > Sources**.
2. In the graph display, click and drag across the peak that represents the spike in traffic.
3. Sort the sources by bandwidth use by selecting the **Bytes (Sent/Received)** header.
4. Drill down into whichever source is associated with the highest amount of bandwidth use by double-clicking it. From this screen, you have an overview of that source's traffic activity.
5. Again, in either the **Applications** or **Destinations** view, select the **Bytes (Sent/Received)** header to sort by bandwidth use.
6. Double-click the top entry to drill down to the final inspection level, from which you can access further details on the application or destination, and/or apply a filter to prohibit or limit access.

Only FortiGate models 100D and above support the 24 hour historical data.

Destinations

The **Destinations** console provides information about the destination IP addresses of traffic on your FortiGate unit, as well as the application used. You can drill down the displayed information, and also select the device and time period, and apply search filters.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Result, and Source Interface. For more on filters, see [Filtering options](#).

Scenario: Monitoring destination data

The Destinations console can be used to access detailed information on user destination-accessing through the use of the console's drilldown functionality. In this scenario, the console is used to find out more about a particular user's Facebook usage patterns over a 24-hour period:

1. Go to **FortiView > Destinations**.
2. Select **1 hour** from the Time Display options at the top right corner of the console.
3. The easiest way to locate most destinations is to scan the Applications column for the name of the application. Once the session containing Facebook has been located, double-click it to access the Destination summary window.
4. Locate Facebook in the Applications column and double-click it to view the Facebook drilldown page. From here, detailed information regarding the user's Facebook session can be accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Applications

The **Applications** console provides information about the applications being used on your network.

This console can be filtered by Application, Country, Destination Interface, Policy, Result, and Source Interface. For more on filters, see [Filtering options](#).

Specific devices and time periods can be selected and drilled down for deep inspection.

In order for information to appear in the **Applications** console, Application Control must be enabled in a policy.

Scenario: Viewing application usage

A manager is interested in the office internet habits of their employees:

1. Go to **FortiView > Applications**, to view the list of applications accessed by the users on your network. Use the time-frame options to view what applications were used in those time periods (from now, 5 minutes, 1 hour, or 24 hours).
2. From **Sessions (Blocked/Allowed)** and **Bytes (Sent/Received)**, you can see how much traffic has been generated. Click these columns to show the traffic in descending order.
3. You notice that a social media application has created the most traffic of all the applications, and so it's at the top of the list. Drill down into the application by double-clicking or right-clicking and select **Drill Down to Details**.
4. You are directed to a summary page of the social media application. From here, you can see which specific user has made the most use of the application.

Only FortiGate models 100D and above support the 24 hour historical data.

Cloud Applications

The **Cloud Applications** console provides information about the cloud applications being used on your network. This includes information such as:

- The names of videos viewed on YouTube (visible by hovering the cursor over the session entry)
- Files uploaded and downloaded from cloud hosting services such as Dropbox
- Account names used for cloud services

Two different views are available for the Cloud Applications: **Applications** and **Users** (located in the top menu bar next to the time periods). **Applications** shows a list of the programs being used. **Users** shows information on the individual users of the cloud applications, including the username, if the FortiGate was able to view the login event.

This console can be filtered by Cloud Application and Result. For more on filters, see [Filtering options](#).

In order for information to appear in the **Cloud Applications** console, an application control profile (that has Deep Inspection of Cloud Applications turned on) must be enabled in a policy, and SSL Inspection must use `deep-inspection`.

Scenario: Viewing cloud application usage data

From the Cloud Applications console, users can drill down to access detailed data on cloud application usage data. In this scenario, the console is used to determine the network's most frequent user of YouTube over a 24-hour period, and find out more about their usage patterns.

1. Go to **FortiView > Cloud Applications**.
2. Select **Applications** view from the top menu bar if it is not already selected.
3. Select **24 Hours** from the Time Display options.
4. Find **YouTube** under the Application column and double-click it (or right-click and select **Drill down for details...**). This will open the YouTube stats window.
5. To determine the user who has accessed YouTube the most frequently, sort the column entries by **Sessions** by selecting the column header of the same name.
6. Double-click (or right-click and select **Drill down for details...**) the top-bandwidth YouTube user to view detailed stats, including the names of videos watched by the user and the date and time each video was accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Web Sites

The **Web Sites** console lists the top allowed and top blocked web sites. You can view information by domain or by FortiGuard categories by using the options in the top right corner. Each FortiGuard category can be selected in order to see a description of the category and several example sites, with content loaded from FortiGuard on demand.

This console can be filtered by Domain and Result. For more on filters, see [Filtering options](#).

In order for information to appear in the **Web Sites** console, web filtering must be enabled in a policy, with FortiGate Categories enabled.

Scenario: Investigating an instance of Proxy Avoidance

In this scenario, the Categories view will be used to investigate an instance of Proxy Avoidance, one of the Categories recognized by FortiOS. Proxy Avoidance denotes the use of a proxy site in order to access data that might otherwise be blocked by the server.

1. Go to **FortiView > Web Sites** to open the Web Sites console.
 2. Select **Categories** from the top bar menu to enter Categories view.
 3. Scan the **Categories** column and locate the instance of Proxy Avoidance, then double-click it to enter its drilldown screen.
-

Only FortiGate models 100D and above support the 24 hour historical data.

Threats

The **Threats** console lists the top users involved in incidents, as well as information on the top threats to your network.

The following incidents are considered threats:

- Risk applications detected by application control
- Intrusion incidents detected by IPS
- Malicious web sites detected by web filtering
- Malware/botnets detected by antivirus

This console can be filtered by Country, Destination Interface, Policy, Result, Security Action, Source Interface, Threat, and Threat Type. For more on filters, see [Filtering options](#).

In order for information to appear in the **Threats** console, Threat Weight Tracking must be enabled.

Scenario: Monitoring Threats to the Network

Some users have high Threat Scores. The Threats console can be used to view all threats and discover why such high scores are being shown:

1. Go to **FortiView > Threats**. In the graph display, click and drag across the peak that represents the spike in threat score.
2. Sort the threats by score or level by selecting the **Threat Score (Blocked/Allowed)** or the **Threat Level** headers respectively.
3. You see that a specific threat's Threat Level is at Critical. Drill down into the threat by double-clicking or right-clicking and select **Drill down to details**.
4. From this summary page, you can view the source IPs and the number of sessions that came from this threat. Double-click on one of them.
5. The following page shows a variety of statistics, including **Reference**. The URL next to it will link you to a FortiGuard page where it will display the description, affected products, and recommended actions, if you are not familiar with the particular threat.

Only FortiGate models 100D and above support the 24 hour historical data.

WiFi Clients

The **WiFi Clients** console shows a list of all the devices connected to the WLAN. The type of device, source, number of sources blocked and allowed, and bytes sent and received are displayed. The source's Service Set Identifier (SSID) is also displayed in the **Source SSID** column. An SSID is a case sensitive, 32 character alphanumeric identifier that acts as a password when a mobile device tries to connect to the WLAN.

This console can be filtered by AP, Device Type, Result, Source Device, Source IP, Source SSID, and User. For more on filters, see [Filtering options](#).

Scenario: Determining the threat risk of an individual WiFi client

In this scenario, the administrator will use the WiFi Clients FortiView console to determine the risk levels associated with an individual WiFi client, and then drilldown into that client to determine where the risk originates and who might be the offending user/IP.

1. Go to **FortiView > WiFi Clients** and view the device list table.
2. Double-click on a device to filter on that source.
3. Under the **Risk** column, identify the items that present the greatest risk (using the **Applications**, **Destinations**, **Threats**, and/or **Sessions** tabs, for example).
4. Right-click these items for further action.

Traffic Shaping

The **Traffic Shaping** console provides information about FortiGate Traffic Shapers that are currently in effect. This console can be filtered by Traffic Shaper Name. For more on filters, see [Filtering options](#).

A number of columns available in FortiView are only available in Traffic Shaping. For example, the **Shaper** column displays the name of the Shaper, which can be used to monitor the traffic being shaped by Bytes Sent, Received, and Dropped, so that bandwidth patterns and Shaper effectiveness can be analyzed.

Only FortiGate models 100D and above support the 24 hour historical data.

System Events

The **System Events** console lists security events detected by FortiOS, providing a name and description for the events, an assessment of the event's severity level (**Alert**, **Critical**, **Emergency**, **Error**, or **Warning**), and the number of instances the events were detected.

Two other FortiView pages from 5.4 have been wrapped into the **System Events** page as of 5.6: **Admin Logins**, and **Failed Authentication**.

This console can be filtered by Event Name, Result, and Severity. For more on filters, see [Filtering options on page 1286](#).

Scenario: Investigate network security events

System Events can be used in conjunction with All Sessions to see what network security events took place, and specifically see what action was taken upon their detection:

1. Go to **FortiView > System Events** to see what and how many network events have taken place, as well as how severe they are in terms of the threat they pose to the network.
2. You see that a particular event has warranted a severe rating, and has allowed traffic to bypass the firewall. Note when the event took place, and go to **FortiView > All Sessions**, to see more information pertaining to the security event.
3. From this console, you can determine the system event's source, how much traffic was sent and received, and the security action taken in response to this security event. These actions differ, depending upon the severity of the security event. See the entry for **Security Action** in [Columns displayed on page 1291](#).

Only FortiGate models 100D and above support the 24 hour historical data.

VPN

From the **VPN** console, users can access information on any VPNs associated with their FortiGate. From the initial window, a list of all the associated VPNs is provided, along with general information, such as number of user connections and VPN type. By double-clicking on an individual VPN (or right-clicking and selecting **Drill down for details...**), users can access more specific data on that VPN.

Logs in the VPN console can be sorted by number of connections, last connection time, or data sent/received by selecting the column headers.

This console can be filtered by Result, User Name, and VPN Type. For more on filters, see [Filtering options on page 1286](#).

Certain dashboard options will not appear unless your FortiGate has Disk Logging enabled.

Furthermore, only certain FortiGate models support Disk Logging — refer to the [FortiView Feature Support - Platform Matrix on page 1258](#) for more information.

To enable Disk Logging, go to **Log & Report > Log Settings**, and select the checkbox next to **Disk** and apply the change.

Scenario: Investigating VPN user activity

The VPN console can be used to access detailed data on VPN-user activity via the use of the drill down windows. In this scenario, the administrator looks into the usage patterns of the IPsec user who has most frequently connected to the network.

1. Go to **FortiView > VPN** to view the VPN console.
2. Select the **Connections** column header to sort the entries by number of connections to the network.
3. Locate the top user whose VPN Type is **ipsec** and double-click the entry to enter that user's drill down screen.
4. To get the most representative data possible, sort the entries by bandwidth use by selecting the **Bytes (Sent/Received)** column header. Double-click the top entry to enter the drill down window for that connection instance.

From this screen, the administrator can find out more about the specific session, including the date/time of access, the XAuth (Extensible Authentication) User ID, the session's Tunnel ID, and more.

Only FortiGate models 100D and above support the 24 hour historical data.

Endpoint Vulnerability

The **Endpoint Vulnerability** console lists the top devices and vulnerabilities detected, organized either by frequency or risk level.

This console can be filtered by Vulnerability Name, Severity, Vulnerability Category, CVE-ID, or Host Count. For more on filters, see [Filtering options](#).

The Vulnerabilities detected by the FortiGate use definitions created by FortiGuard, and every vulnerability in FortiView contains a link to the respective FortiGuard Labs documentation page (under the '**Vulnerability ID**' column) and the Common Vulnerabilities and Exposures documentation page (under the '**CVE-ID**' column.)

Scenario: Monitoring Vulnerabilities on the Network

When a vulnerability appears in log data, you can use the FortiView page to see more information about it. The Endpoint Vulnerability console can be used to view and track all historical vulnerabilities:

1. Go to **FortiView > Endpoint Vulnerability**. In the upper right, select **Vulnerability**.
2. Sort the threats by frequency by selecting the **Host Count** header.
3. You see that a frequent vulnerability's Severity is at Critical. Drill down into the threat by double-clicking or right-clicking and select **Drill down to details**.
4. From this summary page, you can view the source IPs and devices on which this vulnerability was detected, and also the **Scan Time**. Double-click on one of them.
5. The chart will be filtered to display the specific Endpoint and Vulnerability, offering more granular data about the vulnerability, including its Category and the FortiClient ID of the device. You can access the CVE and FortiGuard links from this page to learn more.

Only FortiGate models 100D and above support the 24 hour historical data.

Threat Map

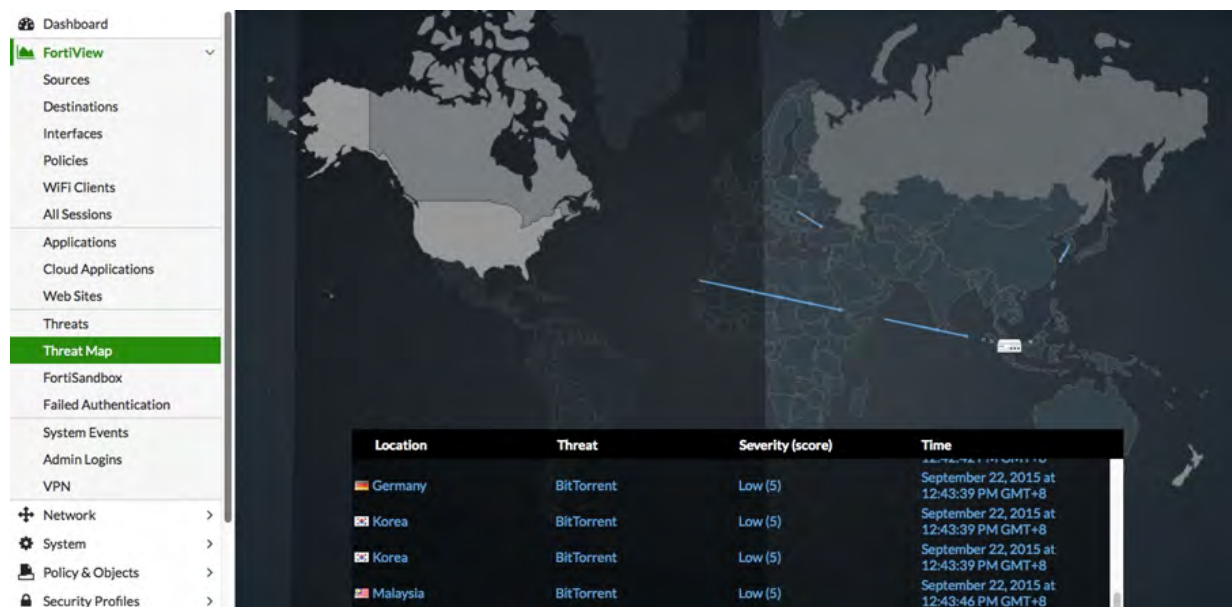

The **Threat Map** console displays network activity by geographic region. Threats from various international destinations will be shown, but only those arriving at your destination, as depicted by the FortiGate. You can place your cursor over the FortiGate's location to display the device name, IP address, and the city name/location.

A visual lists of threats is shown at the bottom, displaying the location, severity, and nature of the attacks. The color gradient of the darts on the map indicate the traffic risk, where red indicates the more critical risk.

Unlike other FortiView consoles, this console has no filtering options, however you can click on any country to drill down into greater (filtered) detail.

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate various international threats

The Threat Map console can be used to regionalize areas that you are more interested in, and disregard regions that you are not interested in:

1. Go to **FortiView > Threat Map** to see a real-time map of the globe. This will show various incoming threats from multiple destinations around the world, depending upon where the FortiGate is placed on the map.
2. You are not interested with threats that are being sent to Eastern Europe, however you are concerned with threats that may be sent to a city in North America. Click and drag the FortiGate to the approximate location where you would like to monitor the incoming threats.
3. To see which countries are sending the more severe threats to your region/location, either see where the red darts are coming from, or check the visual lists of threats at the bottom.

Policies

The **Policies** console shows what policies are in affect on your network, what their source and destination interfaces are, how many sessions are in each policy, and what sort of traffic is occurring, represented in bytes sent and received.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Source, Source Device, and Source Interface. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate which policies are in effect

You can click on policy IDs to drill down to the policy list and see what policy's are in effect for specific interfaces, how many sessions have occurred, how many of those with the policy have been blocked, and more:

1. Go to **FortiView > Policies**, and double-click on a policy ID to drill down.
2. You will be redirected to a summary screen of the policy ID. From here you can view the source IP of where the policy has been used, what source interface has been using the particular policy, and to verify what sort of threat scores have been measured, both blocked and allowed.

Interfaces

The **Interfaces** console lists the total number of interfaces connected to your network, how many sessions there are in each interface, and what sort of traffic is occurring, represented in both bytes sent and received, and the total bandwidth used.

This console can be filtered by Country, Destination Interface, Destination IP, Policy, Result, Source, and Source Interface. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

Scenario: Investigate traffic spikes per user

The wan1 interface is showing a higher amount of traffic than usual. A system administrator uses the console to inspect which user (as represented by an IP address) is creating the spike in traffic:

1. Go to **FortiView > Interfaces** and double-click on wan1, or right click and select **Drill Down to Details...**
2. The console will drill down to a summary page of wan1, showing how many bytes are being sent and received, how much bandwidth is being used, and how many sessions are currently using this interface. You see the IP address of the user that is showing the most amount of traffic under **Source**.
3. You can further drill down to see the IP destination, the device, and the applications being used, and other options.

FortiSandbox

The **FortiSandbox** console detects and analyzes advanced attacks designed to bypass traditional security defenses, and has a wide array of features that allow it to prevent future attacks from occurring again.

This console can be filtered by Checksum, File Name, Source, Status, and User Name. For more on filters, see [Filtering options](#).

Only FortiGate models 100D and above support the 24 hour historical data.

All Sessions

The **All Sessions** console provides information about all FortiGate traffic. This console can be filtered by Application, Country, Destination Interface, Destination IP, Destination Port, NAT Source IP, NAT Source Port, Policy, Protocol, Source, Source Interface, Source IP, and Source Port. For more on filters, see [Filtering options](#).

This console has the greatest number of column options to choose from. To choose which columns you wish to view, select the column settings cog at the far right of the columns and select your desired columns. They can then be clicked and dragged in the order that you wish them to appear.

A number of columns available in FortiView are only available in All Sessions. For example, the **Action** column displays the type of response taken to a security event. This function can be used to review what sort of threats were detected, whether the connection was reset due to the detection of a possible threat, and so on. This would be useful to display alongside other columns such as the **Source**, **Destination**, and **Bytes (Sent/Received)** columns, as patterns or inconsistencies can be analyzed.

Similarly, there are a number of filters that are only available in All Sessions, one of which is **Protocol**. This allows you to display the protocol type associated with the selected session, e.g. TCP, FTP, HTTP, HTTPS, and so on.

Scenario: Filtering sessions by port number and application type

From the **All Sessions** console, a wide variety of filters can be applied to sort the session data. In this example, the All Sessions filters will be used to locate a specific user's recent Skype activity.

1. Go to **FortiView > All Sessions**.
2. Select **now** from the **Time Display** options if it is not already selected.
3. Select the **Filter** button, then select **Applications**. This will open a drop-down menu listing the applications that appear in the master session list. From this list, locate and select **Skype**, or type "Skype" into the Search Bar and hit **Enter**. This will filter the session list to only feature Skype usage.
4. Select the **Filter** button again, then select **Destination Port** from the drop-down menu, then locate and select the desired port number. This will add a second filter which will restrict the results to presenting only the Skype data associated with that port number.

Only FortiGate models 100D and above support the 24 hour historical data.

Reference

This section consists of reference information for the various consoles in FortiView. Each console has an assortment of filtering options, drilldown options, and columns that can be displayed. Since many of these options and columns persist through each console, the entire list of options and their descriptions is included below. Attempts have been made to identify the instances where an option or column is only available to a particular console.

This section includes:

Filtering options

When you select the **Add Filter** button, a drop-down list appears with a list of available filtering options. Available options differ based on which console is currently being viewed. The following table explains all of the available filtering options:

Filter option	Description
Accelerated Sessions	You can filter the console on 'FortiASIC' ('Accelerated' versus 'Not Accelerated') sessions.
AP	Filter by Access Point (AP) identification number.
Application	Filter by application name.
Checksum	Filter by checksum value. Checksums are reference digits used to represent the correct datatum of a packet in order to detect errors.
Cloud Application	Filter by cloud application name. Note: This filter is only available in the Cloud Applications console.
Country	Filter by the country from which the source accessed the server.
Destination Interface	Filter by the interface type used by the destination user, e.g. wan1.
Destination IP	Filter by the IP address used by the destination.
Destination Port	Filter by the port used by the destination. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Domain	Filter by domain name. Note: This filter is only available in the Web Sites console.
Event Name	Filter by security event name. Note: This filter is only available in the System Events console.
File Name	Filter by file name. Note: This filter is only available in the FortiSandbox console.
Login Type	Filter by type of login (eg. WEP) associated with the displayed authentication attempt. Note: This filter is only available in the Failed Authentications console.

Filter option	Description
NAT Source IP	Filter by the NAT-translated source IP address. Note: This filter is only available in the All Sessions console, (viewing the now time display).
NAT Source Port	Filter by the NAT-translated source interface. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Policy	Filter by the policy identification number.
Protocol	Filter by the protocol used by the source, e.g. tcp or udp. Note: This filter is only available in the All Sessions console, (viewing the now time display).
Result	Filter by the result of whatever security action was taken by FortiOs in the selected session, eg. Accept (all).
Security Action	Filter by the type of response taken to the security event. The types of possible actions are as follows: Allowed: No threat was detected and the connection was let through. Blocked: A threat was detected and the connection was not let through. Reset: A possible issue was detected and the connection was reset. Traffic Shape: Some data packets may have been delayed to improve system-wide performance.
Severity	Filter by the severity level (Critical , High , Medium or Low) associated with a security event.
Source	Filter by the source IP address.
Source IP	
Source Device	Filter by source device type, e.g. mobile.
Source Interface	Filter by the interface type used by the source user, e.g. wan1.
Source Port	Filter by the source interface. Note: This filter is only available in the All Sessions console, (viewing the now time display).

Filter option	Description
Source SSID	Filter by the Service Set Identifier (SSID) associated with the selected user. An SSID is a case sensitive, 32 character alphanumeric identifier that acts as a password attributed to a mobile device.
Status	Filter by the maliciousness of a file. The types of possible status' are Malicious, High, Medium, Low, Clean, Unknown, and Pending . Note: This filter is only available in the FortiSandbox console.
Threat	Filter by threat name and/or URL
Threat Type	Filter by threat category, e.g. <i>Illegal/Unethical</i> or <i>P2P</i> .
Type	Note: This filter is only available in the Failed Authentications console.
User Name	Filter by user name.
VPN Type	Filter by Virtual Private Network (VPN) protocol type, eg. <i>PPTP</i> . Note: This filter is only available in the VPN console.

Drill-Down Options

Double-click, or right-click, on any entry in a FortiView console and select **Drill Down to Details**, to view the following columns (options vary depending on the console selected):

Drill down options are available for all FortiView consoles except **All Sessions**, **Logical Topology**, and **Physical Topology**.

Option	Description
Applications	Select to drill down by application to view application-related information, including the application name, sessions blocked and allowed, bytes sent and received, and the risk level. You can sort entries by selecting the column header.
Sources	Select to drill down by rows to view source-related information, including IP address, device type, interface type, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Destinations	Select to drill down by destination to view destination-related information, including the IP address and geographic region, interface, threat score, number of sessions blocked and allowed, and bytes sent and received. You can sort entries by selecting the column header.
Countries	Select to drill down by country, including the number of sessions, bytes sent and received, and the bandwidth used. You can sort entries by selecting the column header.
Policies	Select to drill down by the policies in use, including source interface, destination interface, bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Source Interfaces	Select to drill down by source interface, including bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Destination Interfaces	Select to drill down by destination interface, including bytes sent and received, and bandwidth used. You can sort entries by selecting the column header.
Threats	Select to drill down by threat to view threat-related information, including the threat name, category, threat level, threat score, and number of sessions blocked and allowed. You can sort entries by selecting the column header.
Domains	Select to drill down by domain to view domain-related information, including domain name, category, browsing time, threat weight, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Categories	Select to drill down by category to view category-related information, including category name, browsing time, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.

Option	Description
Sessions	Select to drill down by sessions to view session-related information, including date/time, source, destination IP address and geographic region, application name, security action, security event, and bytes sent/received. You can sort entries by selecting the column header.

Columns displayed

The following columns appear in the initial window of the dashboards. Some columns may only be visible by selecting them from the column drop-down menu. Options vary depending on the dashboard selected.

Column name	Description
Action	<p>Displays the type of response taken to a security event. The types of possible actions are as follows:</p> <ul style="list-style-type: none"> • Allowed: No threat was detected and the connection was let through. • Blocked: A threat was detected and the connection was not let through. • Reset: A possible issue was detected and the connection was reset. • Traffic Shape: Some data packets may have been delayed to improve system-wide performance. <p>Note: This column is only available in the All Sessions console.</p>
Application	<p>Displays the application name and service. When Time Display is set to now, you can access further information about an application by selecting the column entry.</p>
Application Category	<p>Displays the type of application used in the selected session, e.g. video player, social media.</p> <p>Note: This column is only available in the All Sessions console.</p>
Application ID	<p>Displays the identification number associated with the application used in the selected session.</p> <p>Note: This column is only available in the All Sessions console.</p>
Application Risk Risk	<p>Displays the application risk level. You can hover the mouse cursor over the entry in the column for additional information, and select the column header to sort entries by level of risk.</p> <p>Risk uses a 5-point risk rating. The rating system is as follows:</p> <ul style="list-style-type: none"> • Critical: Applications that are used to conceal activity to evade detection. • High: Applications that can cause data leakage, are prone to vulnerabilities, or may download malware. • Medium: Applications that can be misused. • Elevated: Applications that are used for personal communications or can lower productivity. • Low: Business-related applications or other harmless applications.

Column name	Description
Bandwidth	Displays information for bandwidth calculated on a per-session level, providing administrators the ability to sort realtime bandwidth usage in descending order.
Browsing Time	<p>Displays the amount of time a user has spent browsing a web site (in seconds).</p> <p>Note: This column is only available in the Web Sites console, in Categories view..</p>
Bytes (Sent/Received)	<p>Displays the size of sent and received data packets, as measured in bytes. Select the column header to sort the entries by size.</p> <p>Note: This information is available on some consoles as two separate columns: Sent and Received.</p>
Category	Displays the category descriptor appropriate to whatever console is being displayed. For example, threat categories are displayed in the Threats console.
Cloud User	<p>Displays the users accessing cloud applications by IP address.</p> <p>Note: This column is only available in the Cloud Applications console, in Users view.</p>
Configuration Changes	<p>Displays the number of configuration changes made by the user. You can hover the mouse cursor over an entry for additional information.</p> <p>Note: This column is only available in the Admin Logins console.</p>
Connections	<p>Displays the number of VPN connections made by the selected user..</p> <p>Note: This column is only available in the VPN console.</p>
Country	<p>Displays the country from which the selected traffic is originating.</p> <p>Note: This column is only available in the Countries console.</p>
Destination	Displays the destination name, IP address and geographic region.
Destination Country	<p>Displays the country session data is being sent to.</p> <p>Note: This column is only available in the All Sessions console.</p>
Destination Interface	Displays which interface session data is being sent through, e.g. wan1.

Column name	Description
Destination Port	Displays the port number of the destination server being used to accept data. Note: This column is only available in the All Sessions console.
Device	Displays the device IP address or Fully Qualified Domain Name (FQDN).
Domain	Displays the domain associated with the selected web site, e.g. google.com. Note: This column is only available in the Web Sites console.
DST Nat IP NAT Destination	Displays the Network Address Translation (NAT) IP address associated with the destination server. Note: This column is only available in the All Sessions console.
DST Nat Port NAT Destination Port	Displays the Network Address Translation (NAT) port number associated with the destination server. Note: This column is only available in the All Sessions console.
Duration	Displays the amount of time (in seconds) a user has been logged in. Note: This column is only available in the Admin Logins console.
Event Name (Description)	Displays the name and description of the selected security event. Note: This column is only available in the System Events console.
Events	Displays the number of security events that occurred within a selected session. Note: This column is only available in the System Events console.
Expires	Displays the amount of time a session has (in seconds) before it is set to expire. Note: This column is only available in the All Sessions console, in now Time Display view.
Failed Logins	Displays the number of failed login attempts made by an administrator over the specified time period. Note: This column is only available in the Admin Logins console.

Column name	Description
Files (Up/Down)	<p>Displays the number of files uploaded and downloaded. Hover the mouse cursor over the entry in the column for additional information.</p> <p>Note: This column is only available in the Cloud Applications console.</p>
FortiASIC	<p>Displays the type of FortiASIC hardware acceleration used in the specified session, if present.</p> <p>Note: This column is only available in the All Sessions console, in the now Time Display view.</p>
Group	<p>Displays the group ID associated with the selected session.</p> <p>Note: This column is only available in the All Sessions console.</p>
Last Connection Time	<p>Displays the most recent instance of connection to the selected Virtual Private Network (VPN).</p> <p>Note: This column is only available in the VPN console.</p>
Level Threat Level	<p>Displays the threat level. Select the column header to sort entries by threat level.</p>
Log ID	<p>Displays the identification number for the data log associated with this entry.</p> <p>Note: This column is only available in the All Sessions console.</p>
Login IDs	<p>Displays the number of login IDs associated with the selected cloud application.</p> <p>Note: This column is only available in the Cloud Applications console, in Applications view.</p>
Login Type	<p>Displays the type of login (eg. WEP) associated with the displayed authentication attempt.</p> <p>Note: This column is only available in the Failed Authentications console.</p>
Logins	<p>Displays the number of successful logins made by an administrator over the specified time period.</p> <p>Note: This column is only available in the Admin Logins console.</p>

Column name	Description
Pending	Note: This column is only available in the FortiSandbox column, in Source view.
Policy ID	Displays the identification number of the policy under which the selected connection was allowed.
Security Action	<p>Displays the action taken in response to the selected security event. The types of possible actions are as follows:</p> <ul style="list-style-type: none"> • Allowed: No threat was detected and the connection was let through. • Blocked: A threat was detected and the connection was not let through. • Reset: A possible issue was detected and the connection was reset. • Traffic Shape: Some data packets may have been delayed to improve system-wide performance.
Sessions	<p>Displays the number of sessions associated with the selected destination.</p> <p>Note: This column only appears in the Destinations console, in the now Time Display view.</p>
Sessions (Blocked/Allowed)	<p>Displays the number of sessions blocked and allowed by FortiOs.</p> <p>In some consoles, entries can be sorted by number of sessions by selecting the column header..</p>
Severity	Displays the severity level (Critical , High , Medium or Low) associated with the selected security event.
Source	Displays the source IP address and/or user ID, if applicable.
Source Interface	Displays which interface is being used by the destination server (eg. wan1).
Source Port	Displays the port number being used by the source server to send data.
Source SSID	<p>Displays the Service Set Identifier (SSID) associated with the selected user.</p> <p>Note: This column is only available in the Wifi Clients console.</p>
Src NAT IP NAT Source	Displays the Network Address Translation (NAT) IP address associated with the source server.

Column name	Description
Src NAT Port NAT Source Port	Displays the Network Address Translation (NAT) port number associated with the source server.
Status	<p>The types of possible status' are Malicious, High, Medium, Low, Clean, Unknown, and Pending.</p> <p>Note: This console is only available in the FortiSandbox console, in Files view.</p>
Submitted	<p>Displays the number of files submitted to the FortiSandbox for assessment in the selected session.</p> <p>Note: This column is only available in the FortiSandbox console, in Files view.</p>
Threat	Displays the threat type detected in the selected session.
Threat Score (Blocked/Allowed)	Displays the threat score value, a measurement of the total number of threats detected over the course of the session. You can select the column header to sort entries by threat score.
Threat Weight	Displays the threat weight profile associated with the selected session.
Timestamp	Displays the selected session's PHP timestamp.
User User Name	Displays the user name associated with the selected administrator.
Videos Played	<p>Displays the number of videos played via cloud applications.</p> <p>Note: This column is only available in the Cloud Applications console.</p>

Risk level indicators

There are currently two consoles within FortiView that display the Risk associated with the console: **Applications** and **Cloud Applications**. Each application pose different levels of risk to the network, represented by a colour code.

The following table identifies each risk level, from least to most severe:

Indicator	Risk	Description
	Green: <i>Risk Level 1</i>	<p>These applications have little to no risk level, with no assigned risk definition. Application file-sharing may result in data leakage, which would be a typical example of a low level risk.</p> <p>An example application would be the Google toolbar, or Dropbox.</p>
	Blue: <i>Risk Level 2</i>	<p>These applications have an elevated risk level and typically use excessive bandwidth. High bandwidth consumption can lead to increased operational costs.</p> <p>An example application would be Bittorrent.</p>
	Yellow: <i>Risk Level 3</i>	<p>These applications have a low risk level and are typically evasive.</p> <p>Evasive applications can lead to compliance risks, and could include applications such as JustinTV and GlypeProxy.</p>
	Orange: <i>Risk Level 4</i>	<p>These applications have a high risk level, and are defined as using both excessive and evasive bandwidth.</p> <p>Example applications would be AutoHideIP and PandoraTV.</p>
	Red: <i>Risk Level 5</i>	<p>Applications that have a high risk level are prone to malware or vulnerabilities that can introduce business continuity risks.</p>

Troubleshooting FortiView

No logging data is displayed

In order for information to appear in the FortiView consoles, disk logging must be selected for the FortiGate unit. To select disk logging, go to **Log & Report > Log Settings**.

Disk logging is disabled by default for some FortiGate units. To enable disk logging, enter the following command in the CLI:

```
config log disk setting
    set status enable
end
```

Only certain FortiGate models support Disk Logging — refer to the [FortiView Feature Support - Platform Matrix](#) on page 1258 for more information.

Logging is enabled, but data is not appearing

Some FortiView consoles require certain features to be enabled and working before they will display any data. For example, the Web Filtering FortiView page requires that a Web Filtering profile be configured in **Security Profiles > Web Filter** and then applied to a policy in **Policy & Objects > IPv4 Policy**.

First, ensure the feature is enabled in **System > Feature Visibility**, and then go to the appropriate page to make sure that the feature is being implemented. If it is working but is producing no data, FortiView will have nothing to display.

Chapter 11 - Fortinet Communication Ports and Protocols

Ports and protocols

This document contains a series of tables showing the communication ports and protocols used between:

- FortiGate
- FortiAnalyzer
- FortiAP-S
- FortiAuthenticator
- FortiClient
- FortiCloud
- FortiDB
- FortiGuard
- FortiMail
- FortiManager
- FortiPortal
- FortiSandbox
- and 3rd-party servers using FSSO.

Additionally, Fortinet's proprietary protocols are documented, showing what Fortinet products they operate with, how they behave, and how they carry out their roles:

- FGCP - FortiGate Clustering Protocol
- FGSP - FortiGate Session Life Support Protocol
- FGFM - FortiGate to FortiManager Protocol
- SLBC - Session-aware Load Balancing Cluster
- Fortinet Security Fabric
- FortiTelemetry/On-Net/FortiClient Endpoint Compliance
- FortiGuard
- FortiLink
- FortiOS WAN optimization
- FSSO - Fortinet Single Sign-On
- OFTP - Optimized Fabric Transfer Protocol
- FortiClient EMS - Enterprise Management Server

Some protocols contain CLI syntax that control their ports and functionality.

What's new in FortiOS 5.6

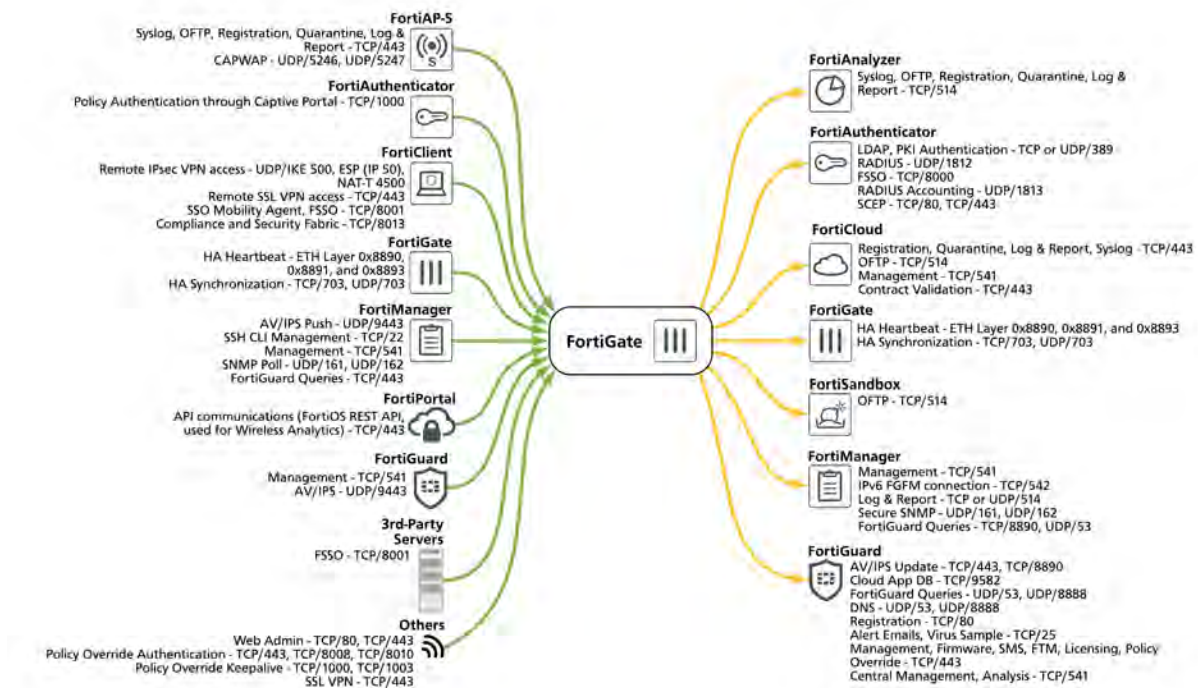

This chapter describes new authentication features added to FortiOS 5.6.

FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

- [FortiGuard communication default port change](#)

FortiGate open ports

Incoming ports

Purpose	Protocol/Port	
FortiAP-S	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/443
	CAPWAP	UDP/5246, UDP/5247
FortiAuthenticator	RADIUS	UDP/1812
	FSSO	TCP/8000
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	Management	TCP/541
	AV/IPS	UDP/9443

Incoming ports		
Purpose		Protocol/Port
FortiManager	AV/IPS Push	UDP/9443
	SSH CLI Management	TCP/22
	Management	TCP/541
	SNMP Poll	UDP/161, UDP/162
	FortiGuard Queries	TCP/443
FortiPortal	API communications (FortiOS REST API, used for Wireless Analytics)	TCP/443
Others	Web Admin	TCP/80, TCP/443
	FSSO	TCP/8000
	Policy Override Authentication	TCP/443, TCP/8008, TCP/8010
	FortiClient Portal	TCP/8009
	Policy Override Keepalive	TCP/1000, TCP/1003
	SSL VPN	TCP/10443
3rd-Party Servers	FSSO	TCP/8000

Outgoing ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
FortiAuthenticator	LDAP, PKI Authentication	TCP or UDP/389
FortiCloud	Registration, Quarantine, Log & Report, Syslog	TCP/443
	OFTP	TCP/514
	Management	TCP/541
	Contract Validation	TCP/443

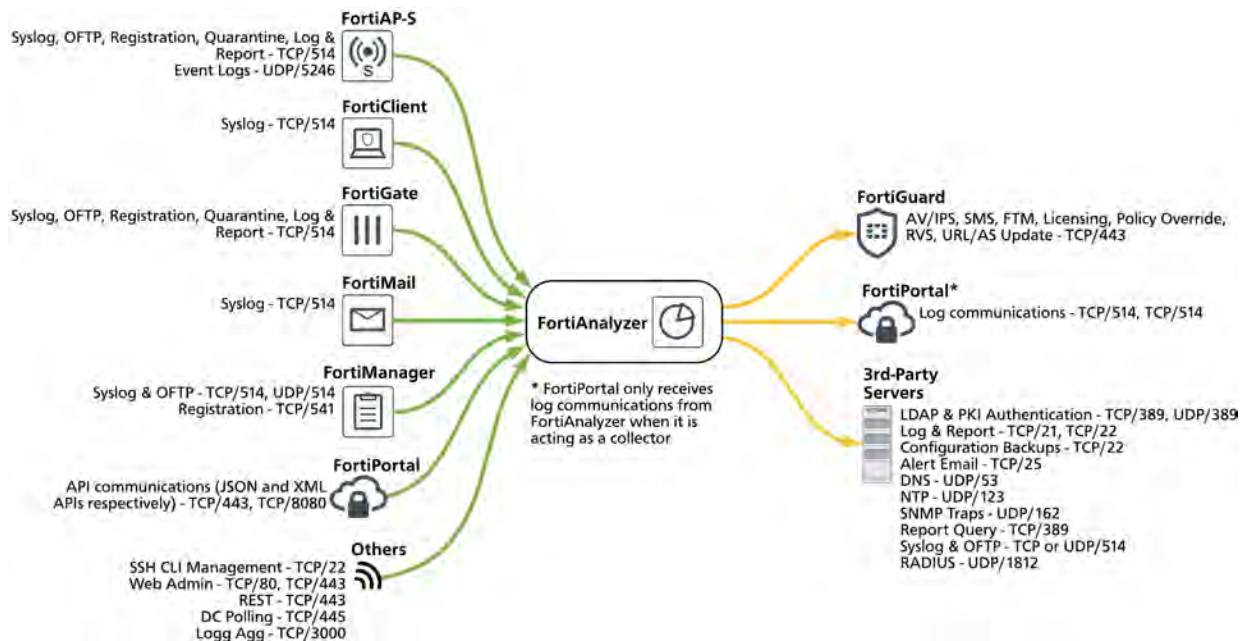

Outgoing ports		
Purpose		Protocol/Port
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	AV/IPS Update	TCP/443, TCP/8890
	Cloud App DB	TCP/9582
	FortiGuard Queries	UDP/53, UDP/8888
	DNS	UDP/53, UDP/8888
	Registration	TCP/80
	Alert Email, Virus Sample	TCP/25
	Management, Firmware, SMS, FTM, Licensing, Policy Override	TCP/443
	Central Management, Analysis	TCP/541
FortiManager	Management	TCP/541
	IPv6 FGFM connection	TCP/542
	Log & Report	TCP or UDP/514
	Secure SNMP	UDP/161, UDP/162
	FortiGuard Queries	TCP/8890, UDP/53
FortiSandbox	OFTP	TCP/514

Note that, while a proxy is configured, FortiGate uses the following URLs to access the FortiGuard Distribution Network (FDN):

- update.fortiguard.net
- service.fortiguard.net
- support.fortinet.com

FortiAnalyzer open ports

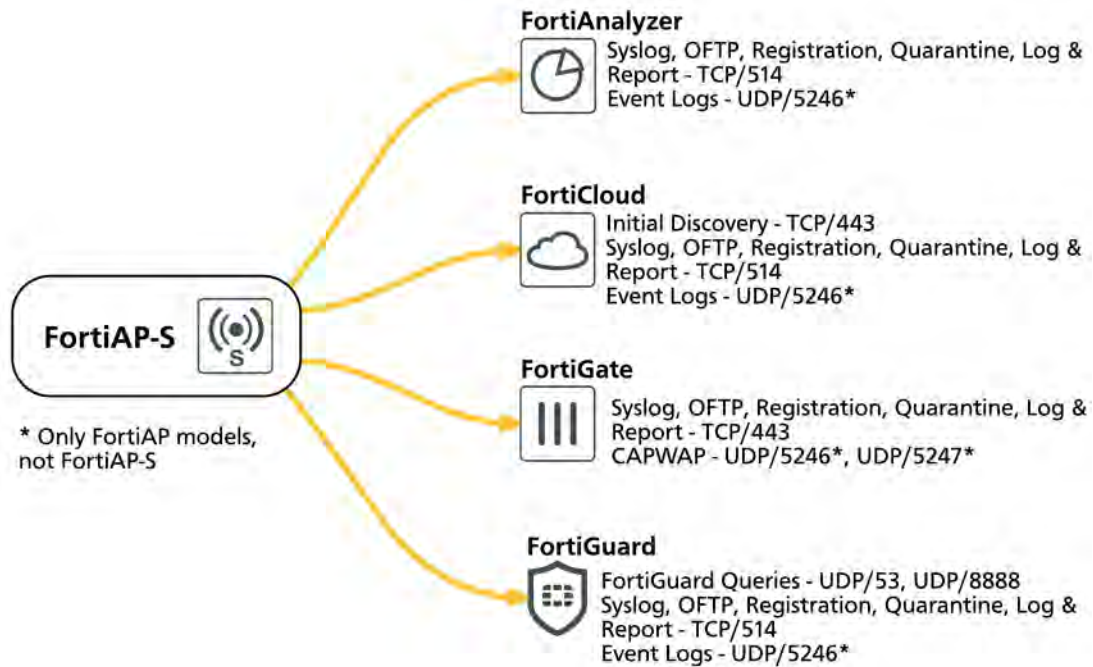

Incoming ports

Purpose		Protocol/Port
FortiAP-S	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246
FortiClient	Syslog	UDP/514
FortiGate	Syslog, OFTP, Registration, Quarantine, Log & Reports	TCP/514
FortiMail	Syslog	UDP/514
FortiManager	Syslog & OFTP	TCP/514, UDP/514
	Registration	TCP/541
FortiPortal	API communications (JSON and XML APIs respectively)	TCP/443, TCP/8080

Incoming ports		
Purpose		Protocol/Port
Others	SSH CLI Management	TCP/22
	Web Admin	TCP/80, TCP/443
	REST	TCP/443
	DC Polling	TCP/445
	Logg Agg	TCP/3000

Outgoing ports		
Purpose		Protocol/Port
FortiGuard	AV/IPS, SMS, FTM, Licensing, Policy Override, RVS, URL/AS Update	TCP/443
FortiPortal (FortiPortal only receives log communications from FortiAnalyzer when it is acting as a collector)	Log communications	TCP/514, UDP/514
3rd-Party Servers	LDAP & PKI Authentication	TCP/389, UDP/389
	Log & Report	TCP/21, TCP/22
	Configuration Backups	TCP/22
	Alert Email	TCP/25
	DNS	UDP/53
	NTP	UDP/123
	SNMP Traps	UDP/162
	Report Query	TCP/389
	Syslog & OFTP	TCP or UDP/514
	RADIUS	UDP/1812

FortiAP-S open ports

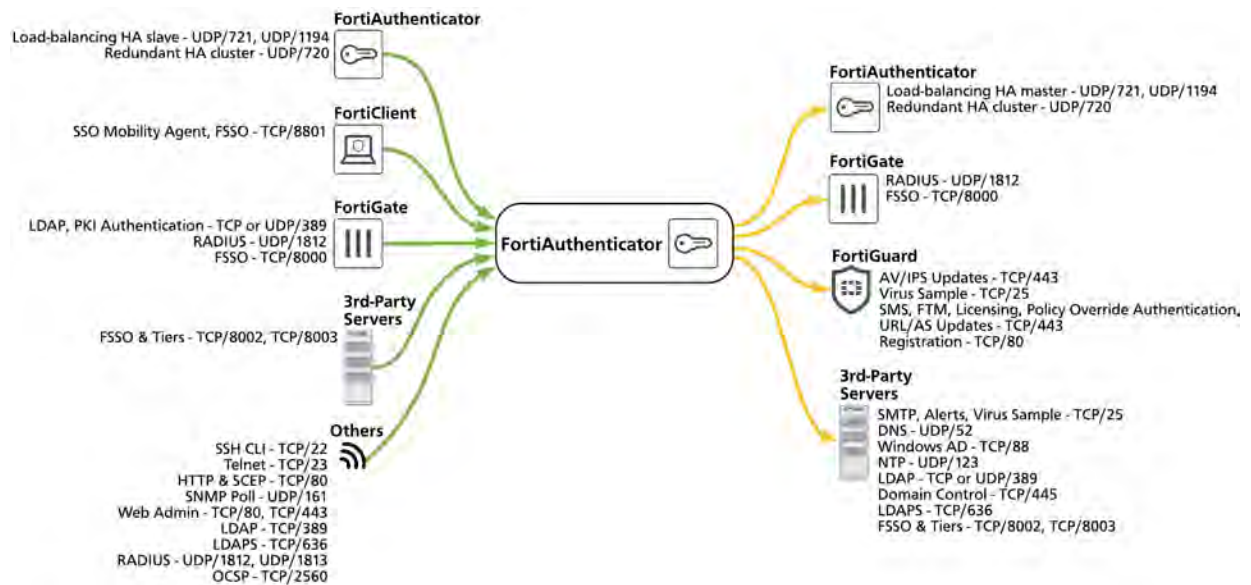

Outgoing ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*
FortiCloud	Initial Discovery	TCP/443
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*
FortiGate	Syslog, Registration, Quarantine, Log & Report	TCP/443
	CAPWAP	UDP/5246*, UDP/5247*

Outgoing ports		
Purpose		Protocol/Port
FortiGuard	FortiGuard Queries	UDP/53, UDP/8888
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246*

* - Only FortiAP models, not FortiAP-S.

FortiAuthenticator open ports

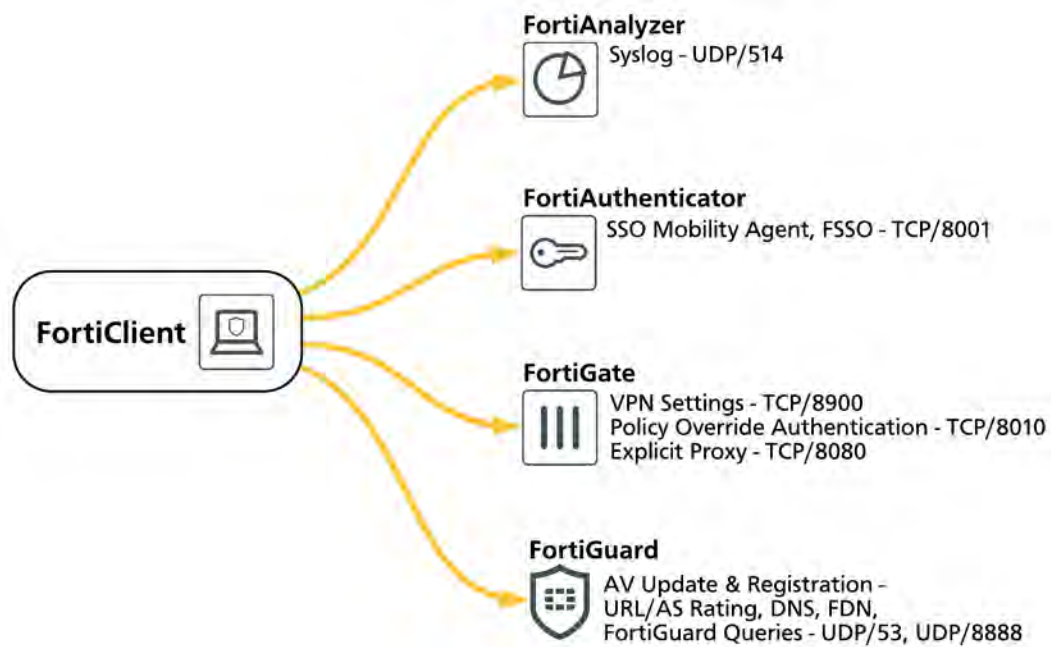

Incoming ports		
Purpose		Protocol/Port
FortiAuthenticator	(HA) HA heartbeat	UDP/720
	LB slave sync	UDP/721, UDP/1194
FortiClient	SSO Mobility Agent, FSSO	TCP/8001
FortiGate	LDAP, PKI Authentication	TCP or UDP/389
	RADIUS	UDP/1812
	FSSO	TCP/8000

Incoming ports		
Purpose		Protocol/Port
Others	SSH CLI	TCP/22
	Telnet	TCP/23
	HTTP & SCEP	TCP/80
	SNMP Poll	UDP/161
	Web Admin	TCP/80, TCP/443
	LDAP	TCP/389
	LDAPS	TCP/636
	RADIUS	UDP/1812, UDP/1813
	OCSP	TCP/2560
3rd-Party Servers	FSSO & Tiers	TCP/8002, TCP/8003

Outgoing ports		
Purpose		Protocol/Port
FortiAuthenticator	(HA) HA heartbeat	UDP/720
	(LB slave) LB slave sync	UDP/721, UDP/1194
FortiGate	RADIUS	UDP/1812
	FSSO	TCP/8000
FortiGuard	AV/IPS Updates	TCP/443
	Virus Sample	TCP/25
	SMS, FTM, Licensing, Policy Override Authentication, URL/AS Updates	TCP/443
	Registration	TCP/80

Outgoing ports		
Purpose		Protocol/Port
3rd-Party Servers	SMTP, Alerts, Virus Sample	TCP/25
	DNS	UDP/52
	Windows AD	TCP/88
	NTP	UDP/123
	LDAP	TCP or UDP389
	Domain Control	TCP/445
	LDAPS	TCP/636
	FSSO & Tiers	TCP/8002, TCP/8003

FortiClient open ports

Outgoing ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog	UDP/514
FortiAuthenticator	SSO Mobility Agent, FSSO	TCP/8001
FortiGate	VPN Settings	TCP/8900
	Policy Override Authentication	TCP/8010
	Explicit Proxy	TCP/8080
FortiGuard	AV Update & Registration	TCP/80
	URL/AS Rating, DNS, FDN, FortiGuard Queries	UDP/53, UDP/8888

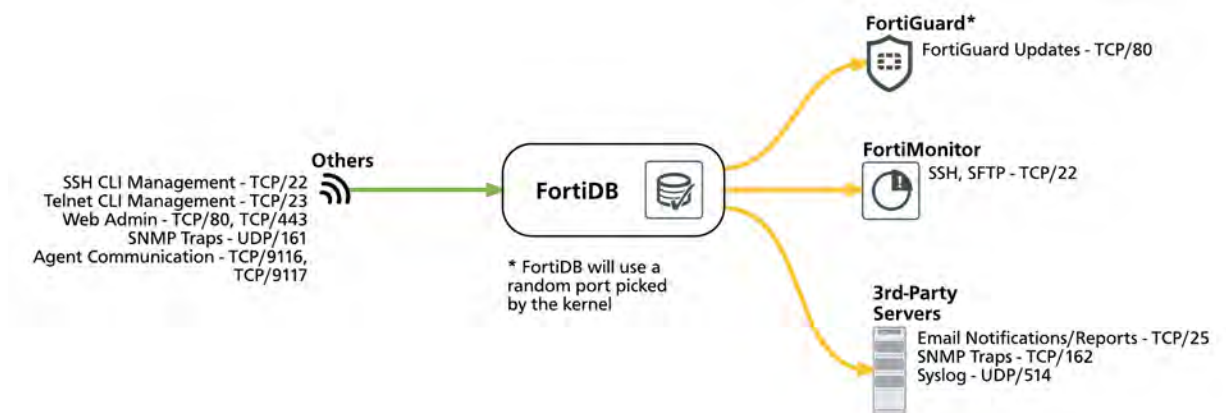

FortiCloud open ports

Incoming ports		
Purpose		Protocol/Port
FortiAP-S	Initial Discovery	TCP/443
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246
FortiGate	Registration, Quarantine, Log & Report, Syslog	TCP/443
	OFTP	TCP/514
	Management	TCP/541
	Contract Validation	TCP/443

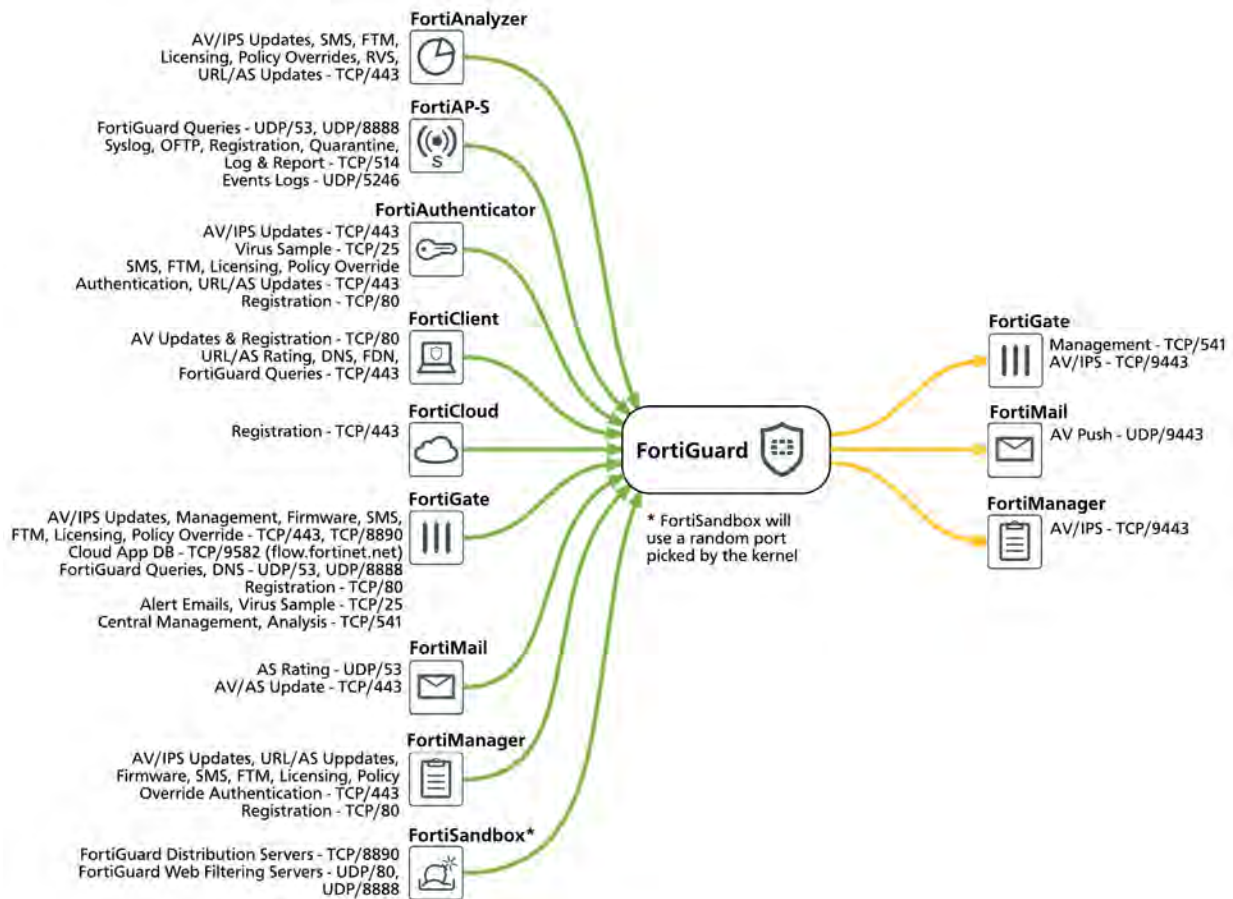

Outgoing ports		
Purpose		Protocol/Port
FortiGuard	Registration	TCP/443

FortiDB open ports

Incoming ports		
Purpose		Protocol/Port
Others	SSH CLI Management	TCP/22
	Telnet CLI Management	TCP/23
	Web Admin	TCP/80, TCP/443
	SNMP Traps	UDP/161
	Agent Communication	TCP/9116, TCP/9117
Outgoing ports		
Purpose		Protocol/Port
FortiGuard (FortiDB will use a random port picked by the kernel)	FortiGuard Updates	TCP/80
FortiMonitor	SSH, SFTP	TCP/22
3rd-Party Servers	Email Notifications/Reports	TCP/25
	SNMP Traps	UDP/162
	Syslog	UDP/514

FortiGuard open ports

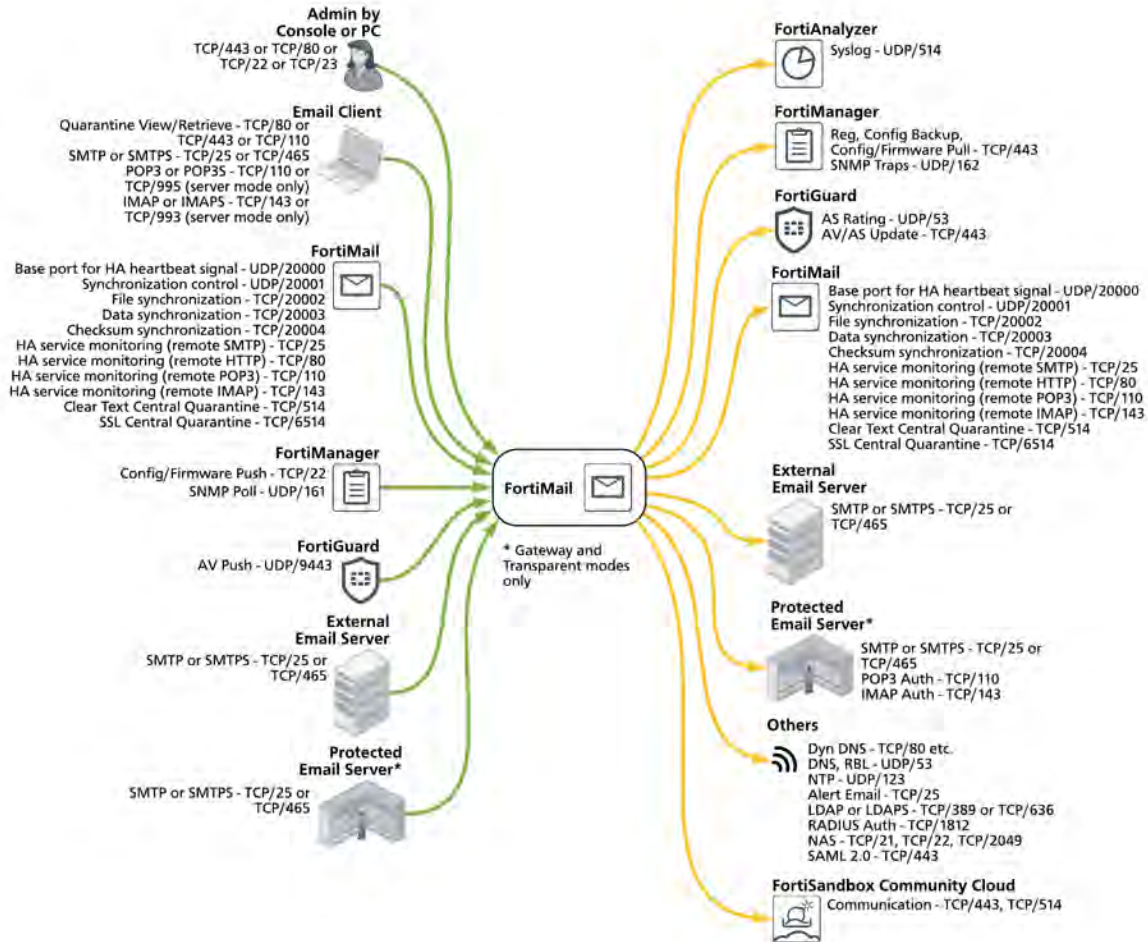

Incoming ports		
Purpose		Protocol/Port
FortiAnalyzer	AV/IPS Updates, SMS, FTM, Licensing, Policy Overrides, RVS, URL/AS Update	TCP/443
FortiAP-S	FortiGuard Queries	UDP/53, UDP/8888
	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
	Event Logs	UDP/5246

Incoming ports		
Purpose		Protocol/Port
FortiAuthenticator	AV/IPS Updates	TCP/443
	Virus Sample	TCP/25
	SMS, FTM, Licensing, Policy Override Authentication, URL/AS Updates	TCP/443
	Registration	TCP/80
FortiClient	AV Update & Registration	TCP/80
	URL/AS Rating, DNS, FDN, FortiGuard Queries	UDP/53, UDP/8888
FortiCloud	Registration	TCP/443
FortiGate	AV/IPS Update, Management, Firmware, SMS, FTM, Licensing, Policy Override	TCP/443, TCP/8890
	Cloud App DB	TCP/9582 (flow.fortinet.net)
	FortiGuard Queries, DNS	UDP/53, UDP/8888
	Registration	TCP/80
	Alert Emails, Virus Sample	TCP/25
	Central Management, Analysis	TCP/541
FortiMail	AS Rating	UDP/53
	AV/AS Update	TCP/443
FortiManager	AV/IPS Updates, URL/AS Update, Firmware, SMS, FTM, Licensing, Policy Override Authentication, Registration	TCP/443
	FortiClient updates	TCP/80
FortiSandbox (FortiSandbox will use a random port picked by the kernel)	FortiGuard Distribution Servers	TCP/8890
	FortiGuard Web Filtering Servers	UDP/53, UDP/8888

Outgoing ports		
Purpose		Protocol/Port
FortiGate	Management	TCP/541
	AV/IPS	UDP/9443
FortiMail	AV Push	UDP/9443
FortiManager	AV/IPS	UDP/9443

FortiMail open ports

When operating in its default configuration, FortiMail does not accept TCP or UDP connections on any port except port1 and port2 network interfaces, which accept:

- ICMP pings,
- HTTPS connections on TCP/443,
- and SSH connections on TCP/22.

Incoming ports		
Purpose		Protocol/Port
Admin by Console or PC	SSH, Telnet, HTTP, SSH, Console	TCP/443 or TCP/80 or TCP/22 or TCP/23
Email Client	Quarantine View/Retrieve	TCP/80 or TCP/443 or TCP/110
	SMTP or SMTPS	TCP/25 or TCP/465
	POP3 or POP3S	TCP/110 or TCP/995 (server mode only)
	IMAP or IMAPS	TCP/143 or TCP/993 (server mode only)
	WebDAV and CalDAV	TCP/8008
FortiMail	Base port for HA heartbeat signal	UDP/20000
	Synchronization control	UDP/20001
	File synchronization	TCP/20002
	Data synchronization	TCP/20003
	Checksum synchronization	TCP/20004
	HA service monitoring (remote SMTP)	TCP/25
	HA service monitoring (remote HTTP)	TCP/80
	HA service monitoring (remote POP3)	TCP/110
	HA service monitoring (remote IMAP)	TCP/143
	Clear Text Central Quarantine	TCP/514
	SSL Central Quarantine	TCP/6514
FortiManager	SNMP Poll	TCP/161
	AV Push	
FortiGuard	AV Push	UDP/9443

Incoming ports		
Purpose		Protocol/Port
External Email Server	SMTP or SMTPS	TCP/25 or 465
	Storage: iSCSI, NFS	TCP/3260 (iSCSI), TCP/2049 (NFS)
	Config Backup	SFTP / FTP
	Mail Data Backup	NFS, SMB/CIFS, SSH, external USB (direct connected), iSCSI
Protected Email Server	SMTP or SMTPS	TCP/25 or 465

Outgoing ports		
Purpose		Protocol/Port
FortiAnalyzer	OFTP	UDP/514
FortiManager	SNMP Traps	UDP/162
	AV/AS Query	
FortiGuard	AS Rating	UDP/53 or 8888, 8889
	AV/AS Update	TCP/443

Outgoing ports		
Purpose		Protocol/Port
FortiMail	Base port for HA heartbeat signal	UDP/20000
	Synchronization control	UDP/20001
	File synchronization	TCP/20002
	Data synchronization	TCP/20003
	Checksum synchronization	TCP/20004
	HA service monitoring (remote SMTP)	TCP/25
	HA service monitoring (remote HTTP)	TCP/80
	HA service monitoring (remote POP3)	TCP/110
	HA service monitoring (remote IMAP)	TCP/143
	Clear Text Central Quarantine	TCP/514
	SSL Central Quarantine	TCP/6514
External Email Server	SMTP or SMTPS	TCP/25 or TCP/465
Protected Email Server	SMTP or SMTPS	TCP/25 or TCP/465
	POP3 Auth	TCP/110
	IMAP Auth	TCP/143
Others	Dyn DNS	TCP/80 *
	DNS, RBL	UDP/53
	NTP	UDP/123

FortiSandbox / FortiSandbox Cloud	Communication	TCP/443, TCP/514

* - FortiMail generates outbound traffic and sends an HTTP SYN request via TCP/80. The Fortinet RSS Feed widget provides a convenient display of the latest security advisories and discovered threats from Fortinet. Also, if an email message contains a shortened URI that redirects to another URI, it would cause FortiMail to send an HTTP SYN request to the shortened URI to get the redirected URI.

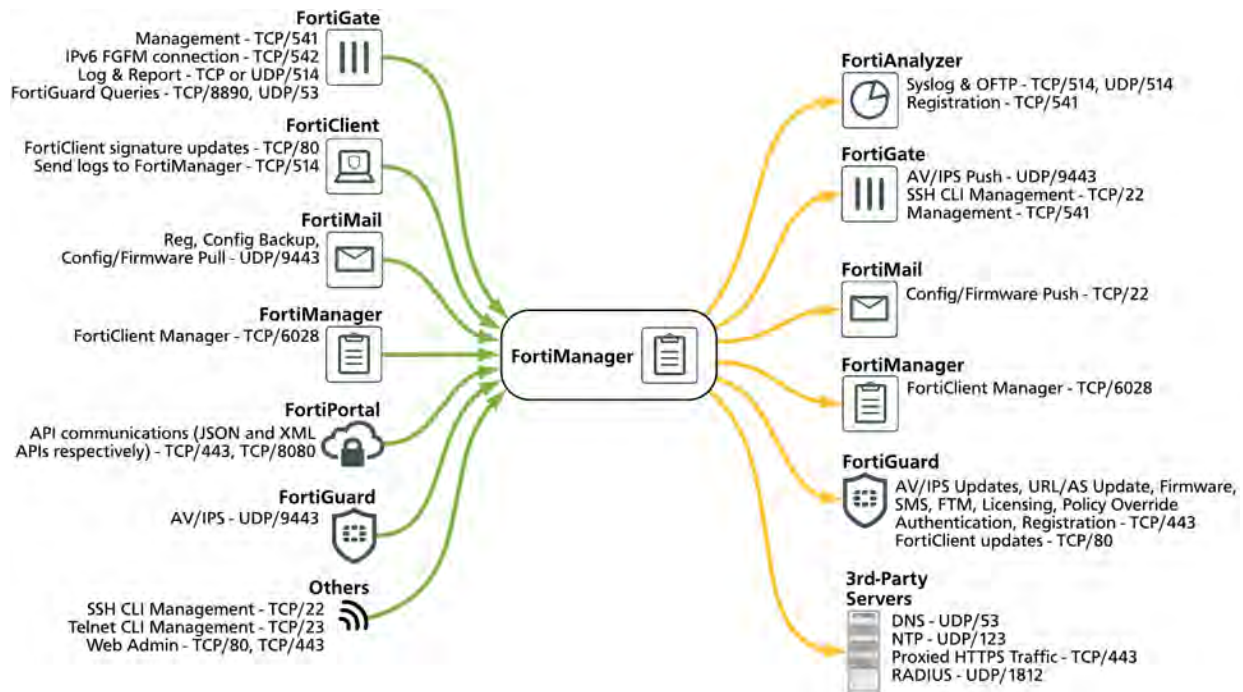

Note that FortiMail uses the following URLs to access the FortiGuard Distribution Network (FDN):

- **update.fortiguard.net**
- **service.fortiguard.net**
- **support.fortinet.com**

Furthermore, FortiMail performs these queries and updates listed below using the following ports and protocols:

- FortiGuard Antispam rating queries: UDP/53, 8888, 8889
- FortiGuard AntiVirus Push updates: UDP/9443
- FortiGuard Antispam or AntiVirus updates: TCP/443

FortiSandbox Community Cloud (FortiSandbox will use a random port picked by the kernel)	Upload detected malware information	TCP/443, UDP/53

Note that FortiSandbox uses the following FQDNs to access the FortiSandbox Community Cloud, depending on which protocol and port is used:

- TCP/443: **fqdl.fortinet.net**
- UDP/53: **fqsrv.fortinet.net**

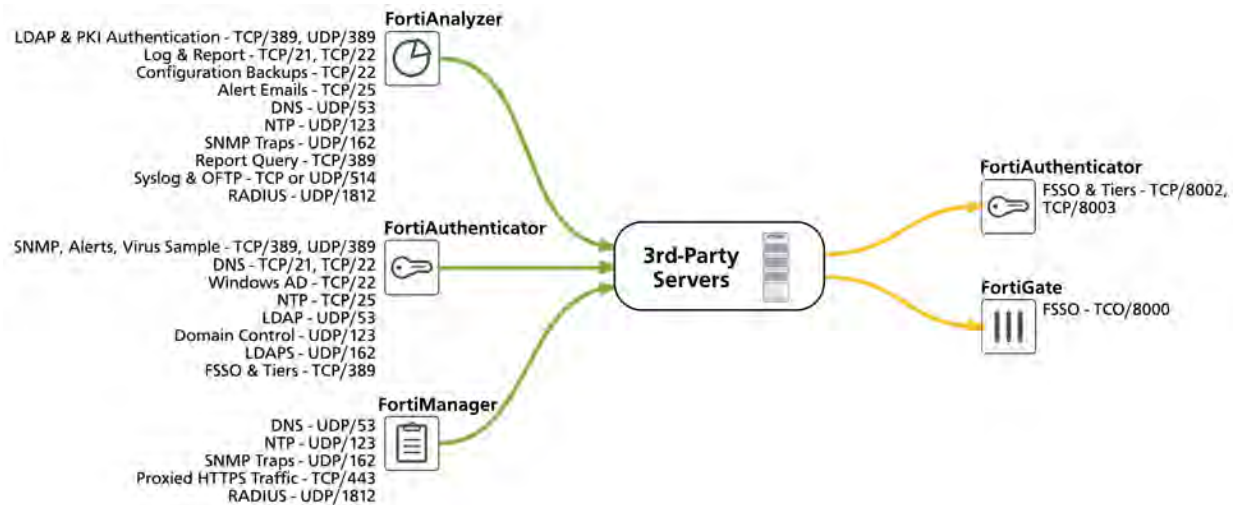

Services and port numbers required for FortiSandbox

The tables above show all the services required for FortiSandbox to function correctly. You can use the diagnostic FortiSandbox command `test-network` to verify that all the services are allowed by the upstream. If the result is `Passed`, then there is no issue. If there is an issue with a specific service, it will be shown in the command output, and inform you which port needs to be opened.

This command checks:

- VM Internet access
- Internet connection
- System DNS resolve speed
- VM DNS resolve speed
- Ping speed
- Wget speed
- Web Filtering service
- FortiSandbox Community Cloud service

Fortinet proprietary protocols

The following section provides a full list of Fortinet's proprietary protocols, their purposes, and what ports they operate on:

- FGCP - FortiGate Clustering Protocol
- FGSP - FortiGate Session Life Support Protocol
- FGFM - FortiGate to FortiManager Protocol
- SLBC - Session-aware Load Balancing Cluster
- Fortinet Security Fabric
- FortiTelemetry/On-Net/FortiClient Endpoint Compliance
- FortiGuard
- FortiLink
- FortiOS WAN optimization
- FSSO - Fortinet Single Sign-On
- OFTP - Optimized Fabric Transfer Protocol
- FortiClient EMS - Enterprise Management Server

FGCP - FortiGate Clustering Protocol

In an active-passive HA configuration, the FortiGate Clustering Protocol (FGCP) provides failover protection, whereby the cluster can provide FortiGate services even when one of the cluster units loses connection. FGCP is also a Layer 2 heartbeat that specifies how FortiGate units communicate in an HA cluster and keeps the cluster operating.

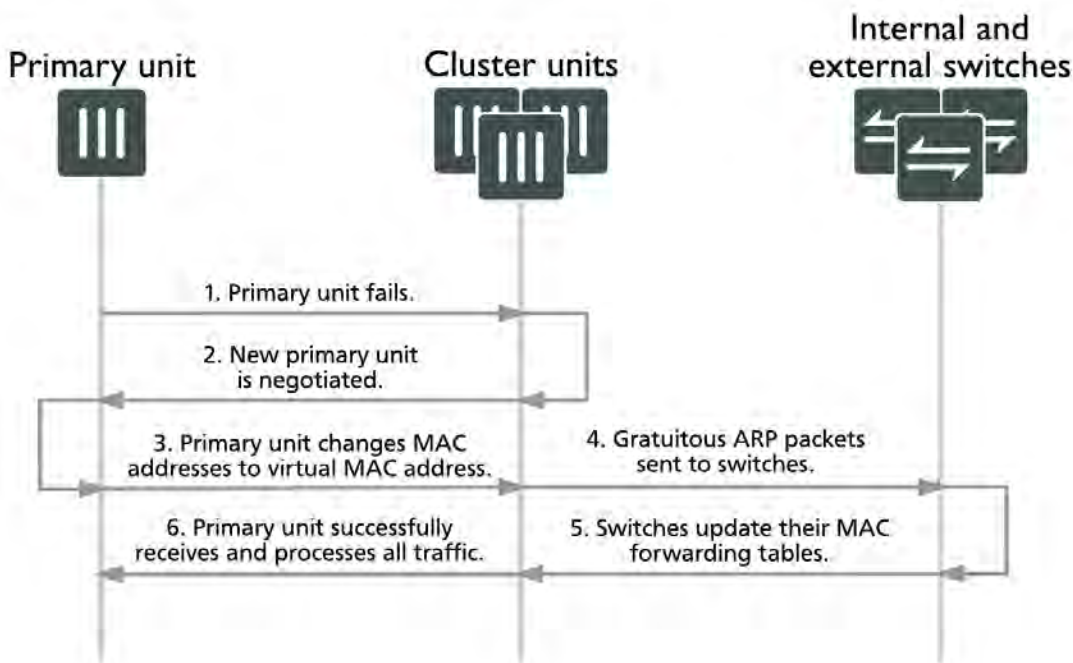

You cannot mix FGCP and SLBC clusters in the same chassis.

The FortiGate's HA Heartbeat listens on ports TCP/703, TCP/23, or ETH layer 2/8890.

Virtual MAC addresses

FGCP assigns virtual MAC addresses to each primary unit interface in an HA cluster. Virtual MAC addresses are in place so that, if a failover occurs, the new primary unit interfaces will have the same MAC addresses as the failed primary unit interfaces. If the MAC addresses were to change after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in Transparent mode, FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

When a cluster starts up, after a failover, the primary unit sends gratuitous ARP packets to update the switches connected to the cluster interfaces with the virtual MAC address. The switches update their MAC forwarding tables with this MAC address. As a result, the switches direct all network traffic to the primary unit. Depending on the cluster configuration, the primary unit either processes this network traffic itself or load balances the network traffic among all of the cluster units.

You cannot disable sending gratuitous ARP packets, but you can change the number of packets that are sent (1-60 ARP packets) by entering the following command:

```
config system ha
    set arps <integer>
end
```

You can change the time between ARP packets (1-20 seconds) by entering the following command:

```
config system ha
    set arps-interval <integer>
end
```

Assigning virtual MAC addresses

Virtual MAC addresses are determined based on the following formula:

00-09-0f-09-<group-id_hex>-<vcluster_integer><idx>

where:

- **<group-id_hex>**: The HA group ID for the cluster converted to hexadecimal. The table below lists some example virtual MAC addresses set for each group ID:

Integer group ID	Hexadecimal group ID
0	00
1	01
2	02
3	03
...	...
10	0a
11	0b
...	...
63	3f
...	...
255	ff

- **<vcluster_integer>**: This value is 0 for virtual cluster 1 and 2 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.
- **<idx>**: The index number of the interface. In NAT mode, interfaces are numbered from 0 to x (where x is the number of interfaces). The interfaces are listed in alphabetical order on the web-based manager and CLI. The interface at the top of the interface list is first in alphabetical order by name and has an index of 0. The second interface in the list has an index of 1 and so on. In Transparent mode, the index number for the management IP address is 0.

Every FortiGate unit physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, as it is the actual MAC address of the interface hardware. The current hardware address can be changed, but only when a FortiGate unit is **not** operating in HA. For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP.

You cannot change an interface MAC address and you cannot view MAC addresses from the system interface CLI command.

You can use the `get hardware nic <interface_name_str>` (or `diagnose hardware deviceinfo nic <interface_str>`) command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface, including the current hardware address (as `Current_HWaddr`) and the permanent hardware address (as `Permanent_HWaddr`). For some interfaces, the current hardware address is displayed as `MAC`.

Failover protection

FGCP supports three kinds of failover protection:

1. **Device failover**: Automatically replaces a failed device and restarts traffic flow with minimal impact on the network. All subordinate units in an active-passive HA cluster are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves. The default time interval between HA heartbeats is 200 ms.
2. **Link failover**: Maintains traffic flow if a link fails. In this case, the primary unit does not stop operating, and therefore participates in the negotiation of selecting a new primary unit. The old primary unit then joins the cluster as a subordinate unit. Furthermore, any subordinate units with a link failure are unlikely to become the primary unit in future negotiations.
3. **Session failover**: With session failover (also called session pickup) enabled, the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster. This helps new primary units resume communication sessions with minimal loss of data, avoiding the need to restart active sessions.

Synchronization of configurations

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. However, there are certain settings that are not synchronized between cluster units:

- HA override
- HA device priority

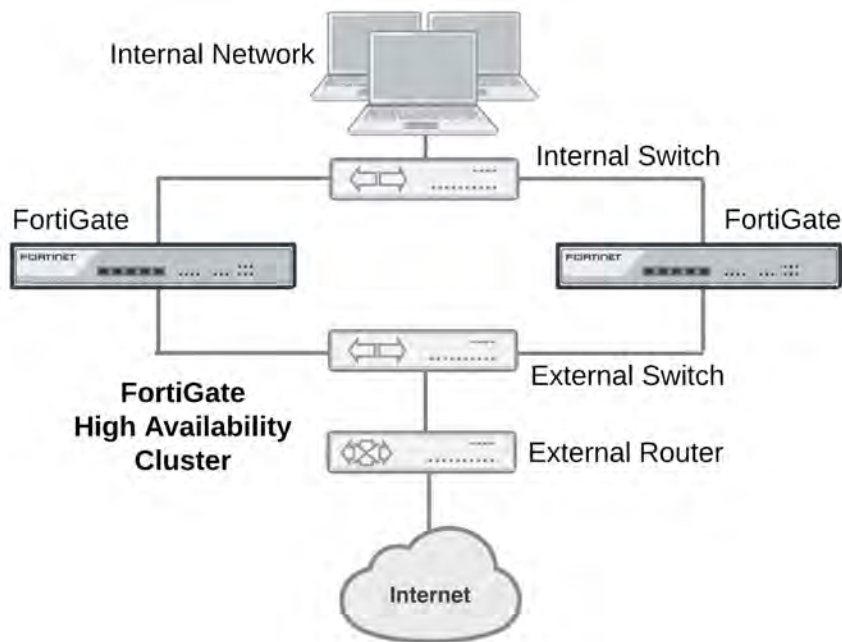

- The virtual cluster priority
- The FortiGate unit host name
- The HA priority setting for a ping server (or dead gateway detection) configuration
- The system interface settings of the HA reserved management interface
- The HA default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.

You can disable configuration synchronization by entering the following command:

```
config system ha
    set sync-config disable
end
```

The command `execute ha synchronize` can be used to perform a manual synchronization.

The FGCP heartbeat operates on TCP port 703 with an independent IP address not assigned to any FortiGate interface. You can create an FGCP cluster of up to four FortiGate units. Below is an example of FGCP used to create an HA cluster installed between an internal network and the Internet.

FGCP HA provides a solution for two key requirements of critical enterprise networking: enhanced reliability and increased performance, through device, link, and remote link failover protection. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

Before configuring an FGCP HA cluster, make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Heartbeat traffic, such as FGCP, uses multicast on port number 6065 and uses link-local IPv4 addresses in the 169.254.0.x range. HA heartbeat packets have an Ethertype field value of **0x8890**.

Synchronization traffic, such as FGSP, uses unicast on port number 6066 and the IP address 239.0.0.2. HA sessions that synchronize the cluster have an Ethertype field value of **0x8893**.

The HA IP addresses are hard-coded and cannot be configured.

How to set up FGCP clustering

This example describes how to enhance the reliability of a network protected by a FortiGate unit by adding a second FortiGate unit to create a FortiGate Clustering Protocol (FGCP) HA cluster. The FortiGate already on the network will be configured to become the primary unit by increasing its device priority and enabling override. The new FortiGate will be prepared by setting it to factory defaults to wipe any configuration changes. Then it will be licensed, configured for HA, and then connected to the FortiGate already on the network. The new FortiGate becomes the backup unit and its configuration is overwritten by the primary unit.

If you have not already done so, register the primary FortiGate and apply licenses to it before setting up the cluster. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMs). You can also install any third-party certificates on the primary FortiGate before forming the cluster.

The FortiGates should be running the same FortiOS firmware version, and their interfaces should not be configured to get their addresses from DHCP or PPPoE.

Configuring the primary FortiGate

1. Connect to the primary FortiGate and go to **Dashboard > System Information**. Change the unit's **Host Name** to identify it as the primary FortiGate.

You can also enter this CLI command:

```
config system global
  set hostname Primary_FortiGate
end
```

2. You then need to set the HA mode to active-passive. Enter the following CLI command to set the HA mode to active-passive, set a group name and password, increase the device priority to a higher value (for example, 250) and enable override:

```
config system ha
  set mode a-p
  set group-name My-HA-Cluster
```

```
set password
set priority 250
set override enable
set hbdev ha1 50 ha2 50
end
```

This command also selects ha1 and ha2 to be the heartbeat interfaces, with their priorities set to 50. Enabling override and increasing the priority ensures that this FortiGate should become the primary unit.

You can configure these settings in the GUI under **System > HA**, however the override can *only* be enabled in the CLI.

Configuring the backup FortiGate

1. Enter the CLI command below to reset the new FortiGate to factory default settings (skip this step if the FortiGate is fresh from the factory). It is recommended to set it back to factory defaults to reduce the chance of synchronization problems.:

```
execute factoryreset
```

2. Make sure to change the firmware running on the new FortiGate to the same version running on the primary unit, register, and apply licenses to it before adding it to the cluster.
3. Then go to **Dashboard > System Information**. Change the unit's **Host Name** to identify it as the backup FortiGate.

You can also enter this CLI command:

```
config system global
  set hostname Backup_FortiGate
end
```

4. Duplicate the primary unit's HA settings, except make sure to set the backup device's priority to a lower value and do *not* enable override.

Connecting the cluster

Connect the HA cluster as shown in the initial diagram above. Making these connections will disrupt network traffic as you disconnect and re-connect cables.

When connected, the primary and backup FortiGates find each other and negotiate to form an HA cluster. The primary unit synchronizes its configuration with the backup FortiGate. Forming the cluster happens automatically with minimal or no disruption to network traffic.

Heartbeat packet EtherTypes

Normal IP packets are 802.3 packets that have an ethernet type (EtherType) field value of 0x0800. EtherType values other than 0x0800 are understood as level 2 frames rather than IP packets.

By default, HA heartbeat packets use the following EtherTypes:

- HA heartbeat packets for NAT mode clusters use EtherType 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the EtherType of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for Transparent mode clusters use EtherType 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the EtherType of these packets using the `hc-eth-type` option of the `config system ha` command.

- HA telnet sessions between cluster units over HA heartbeat links use EtherType 0x8893. The telnet sessions allow an administrator to connect between FortiGates in the cluster using the `execute ha manage` command. You can change the EtherType of these packets using the `l2ep-eth-type` option under `config system ha`.

Because heartbeat packets are recognized as level 2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level 2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these EtherTypes for other purposes. For example, Cisco N5K/Nexus switches use EtherType 0x8890 for some functions. When one of these switches receives EtherType 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

Alternatively, you can use the following CLI options to change the EtherTypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the EtherType of the HA heartbeat packets from 0x8890 to 0x8895 and to change the EtherType of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
  set ha-eth-type 8895
  set l2ep-eth-type 889f
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
  set authentication enable
  set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

FGSP - FortiGate Session Life Support Protocol

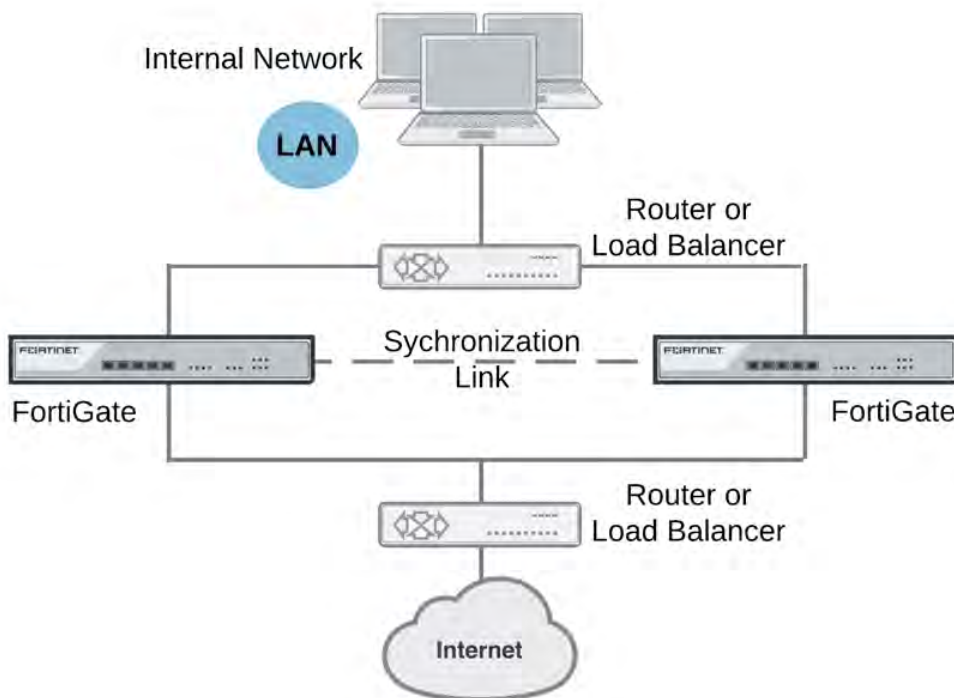

FortiGate Session Life Support Protocol (FGSP) distributes sessions between two FortiGate units and the FGSP performs session synchronization. If one of the peers fails, session failover occurs and active sessions fail over to the peer that is still operating. This failover occurs without any loss of data. Also, the external routers or load balancers will detect the failover and re-distribute all sessions to the peer that is still operating. The two FortiGate units must be the same model and must be running the same firmware.

Note that you cannot configure FGSP HA when FGCP HA is enabled.

You can also use the `config system cluster-sync` command to configure FGSP between two FortiGate units.

The FortiGate's HA Heartbeat listens on ports TCP/703, TCP/23, or ETH Layer 2/8890.

In previous versions of FortiOS, FGSP was called TCP session synchronization or standalone session synchronization. However, FGSP has been expanded to include both IPv4 and IPv6 TCP, UDP, ICMP, expectation, NAT sessions, and IPsec tunnels.

Configuration synchronization

Configuration synchronization can also be performed, allowing you to make configuration changes once for both FortiGate units instead of requiring multiple configuration changes on each FortiGate unit. However interface IP addresses, BGP neighbor settings, and other settings that identify the FortiGate unit on the network are not synchronized. You can enable configuration synchronization by entering the following command:

```
config system ha
    set standalone-config-sync enable
end
```

UDP and ICMP (connectionless) session synchronization

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if it is required, you can configure the FGSP to also synchronize UDP and ICMP sessions by entering the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

Expectation (asymmetric) session synchronization

Synchronizing asymmetric traffic can be very useful in situations where multiple Internet connections from different ISPs are spread across two FortiGates.

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates:

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

Security profile inspection with asymmetric and symmetric traffic

Security profile inspection, flow or proxy based, is **not** expected to work properly if the traffic in the session is load balanced across more than one FortiGate in either direction. However, flow-based inspection should be used in FGSP deployments.

For symmetric traffic, security profile inspection can be used but with the following limitations:

- No session synchronization for the sessions inspected using proxy-based inspection. Sessions will drop and need to be reestablished after data path failover.
- Sessions with flow-based inspection will failover, and inspection of sessions after a failover may not work.

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session failover (also known as session pickup): reducing the number of sessions that are synchronized by adding a session pickup delay, and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

If session pickup is enabled, as soon as new sessions are added to the primary unit session table they are synchronized to the other cluster units. Enable the session-pickup-delay CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
    set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option, you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving session synchronization from the HA heartbeat interface reduces the bandwidth required for HA heartbeat traffic and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
    set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Note that unsetting `session-sync-dev` (i.e. by entering `unset session-sync-dev`) has the following two effects:

1. Session synchronization will use the ports defined as HA heartbeat interfaces (`set hbdev`).
2. Session synchronization packets will be sent over UDP/708 instead of Ethertype 0x8892.

NAT session synchronization

NAT sessions are not synchronized by default. You can enable NAT session synchronization by entering the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-nat enable
end
```

Note that, after a failover with this configuration, all sessions that include the IP addresses of interfaces on the failed FortiGate unit will have nowhere to go since the IP addresses of the failed FortiGate unit will no longer be on the network. If you want NAT sessions to resume after a failover you should not configure NAT to use the destination interface IP address, since the FGSP FortiGate units have different IP addresses. To avoid this issue, you should use IP pools with the type set to `overload` (which is the default IP pool type), as shown in the example below:

```
config firewall ippool
    edit FGSP-pool
        set type overload
        set startip 172.20.120.10
        set endip 172.20.120.20
    end
```

In NAT mode, only sessions for route mode security policies are synchronized. FGSP HA is also available for FortiGate units or virtual domains operating in Transparent mode. Only sessions for normal Transparent mode policies are synchronized.

IPsec tunnel synchronization

When you use the `config system cluster-sync` command to enable FGSP, IPsec keys and other runtime data are synchronized between cluster units. This means that if one of the cluster units goes down the cluster unit that is still operating can quickly get IPsec tunnels re-established without re-negotiating them. However, after a failover, all existing tunnel sessions on the failed FortiGate have to be restarted on the still operating FortiGate.

IPsec tunnel sync only supports dialup IPsec. The interfaces on both FortiGates that are tunnel endpoints must have the same IP addresses and external routers must be configured to load balance IPsec tunnel sessions to the FortiGates in the cluster.

Standalone configuration synchronization uses a very similar process as FGCP. There is a similar relationship between the two FortiGates but only in regards to configuration synchronization, not session information. The primary unit is selected by using priority/override. The heartbeat is used to check the primary unit's health. Once heartbeat loss is detected, a new primary unit is selected.

Automatic session synchronization after peer reboot

The following command allows you to configure an automatic session synchronization after a peer FGSP unit has rebooted. FGSP will send out heartbeat signals (every 1 - 10 seconds, as shown below) if one FortiGate is rebooting and the other FortiGate fails.

To configure automatic session synchronization:

```
config system session-sync
  edit 1
    set down-intfs-before-sess-sync <interfaces> - List of interfaces to be turned down before session
      synchronization is complete.
    set-hb-interval <integer> - (1 - 10 seconds)
    set hb-lost-threshold <integer> - (1 - 10)
  next
end
```

FGFM - FortiGate to FortiManager Protocol

The FortiGate to FortiManager (FGFM) protocol is designed for FortiGate and FortiManager deployment scenarios, especially where NAT is used. These scenarios include the FortiManager on public internet while the FortiGate unit is behind NAT, FortiGate unit is on public internet while FortiManager is behind NAT, or both FortiManager and FortiGate unit have routable IP addresses.

The FortiManager unit's Device Manager uses FGFM to create new device groups, provision and add devices, and install policy packages and device settings.

Port 541 is the default port used for FortiManager traffic on the internal management network. Port 542 is also used to establish IPv6 connection.

Adding a FortiGate to the FortiManager

Adding a FortiGate unit to a FortiManager requires configuration on both devices. This section describes the basics to configure management using a FortiManager device.

FortiGate configuration

Adding a FortiGate unit to FortiManager will ensure that the unit will be able to receive antivirus and IPS updates and allow remote management through the FortiManager system, or FortiCloud service. The FortiGate unit can be in either NAT or transparent mode. The FortiManager unit provides remote management of a FortiGate unit over TCP port 541.

You must first enable **Central Management** on the FortiGate so management updates to firmware and FortiGuard services are available:

1. Go to **System > Settings**.
2. Set **Central Management** to **FortiManager**.
3. Enter the FortiManager's **IP/Domain Name** in the field provided, and select **Send Request**.

You can also select **Registration Password** and enter a password to connect to the FortiManager.

To configure the previous steps in the CLI, enter the following - note that `fmg` can be set to either an IP address or FQDN:

```
config system central-management
    set fmg <string>
end
```

To use the registration password, enter the following:

```
execute central-mgmt register-device <fmg-serial-no> <fmg-register-password> <fgtusrname>
    <fgt-password>
```

FGFM is also used in ADOMs (Administrative Domains) set to Normal Mode. Normal Mode has Read/Write privileges, where the administrator is able to make changes to the ADOM and manage devices from the FortiManager. FortiGate units in the ADOM will query their own configuration every five seconds. If there has been a configuration change, the FortiGate unit will send a revision on the change to the FortiManager using the FGFM protocol.

To configure central management on the FortiGate unit, enter the following on the FortiGate:

```
config system central-management
```

```

set mode normal
set fortimanager-fds-override enable
set fmg <string>
end

```

Configuring an SSL connection

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for **High**, **Medium**, and **Low** follow the openssl definitions below:

Encryption level	Key strength	Algorithms used
High	Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.	DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA
Medium	Key strengths of 128 bit encryption.	RC4-SHA:RC4-MD5:RC4-MD
Low	Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites.	EDH-RSA-DES-CBC-SHA; DES-CBC-SHA; DES-CBC-MD5

An SSL connection can be configured between the two devices and an encryption level selected. To configure the connection in the CLI, Enter the following:

```

config system central-management
set status enable
set enc-algorithm {default | high | low}
end

```

Note that `default` automatically sets high and medium encryption algorithms.

FortiManager configuration

Use the **Device Manager** pane to add, configure, and manage devices.

You can add existing operational devices, unregistered devices, provision new devices, and add multiple devices at a time.

Adding an operating FortiGate HA cluster to the **Device Manager** pane is similar to adding a standalone device. Type the IP address of the master device. The FortiManager will handle the cluster as a single managed device.

To confirm that a device model or firmware version is supported by current firmware version running on FortiManager, enter the following CLI command:

```
diagnose dvm supported-platforms list
```

Replacing a FortiGate in a FortiManager configuration

FGFM can be used in order to re-establish a connection between a FortiGate unit and a FortiManager configuration. This is useful for if you need a FortiGate unit replaced following an RMA hardware replacement. This applies to a FortiGate running in HA as the primary units; it does not apply to subordinate units.

When the FortiGate unit is replaced, perform a Device Manager Connectivity check or Refresh on the FortiManager to establish the FGFM management tunnel to the FortiGate. If it fails, to establish, you can force the tunnel by executing the following command on the FortiManager:

```
execute fgfm reclaim-dev-tunnel <device_name>
```

Debugging FGFM on FortiManager

- To display diagnostic information for troubleshooting (Set the debug level of FGFM daemon. Enter a device name to only show messages related to that device):

```
diagnose debug application fgfmsd <integer> <device_name>
```

- To view installation session, object, and session lists:

```
diagnose fgfm install-session
diagnose fgfm object-list
diagnose fgfm session-list <device_ID>
```

- To reclaim a management tunnel (device name is optional):

```
execute fgfm reclaim-dev-tunnel <device_name>
```

- To view the link-local address assigned to the FortiManager:

```
diagnose fmnetwork interface list
```

Debugging FGFM on FortiGate

- To view information about the Central Management System configuration:

```
get system central-management
```

- To produce realtime debugging information:

```
diagnose debug application fgfmd -1
```

- To view the link-local address assigned to the FortiManager:

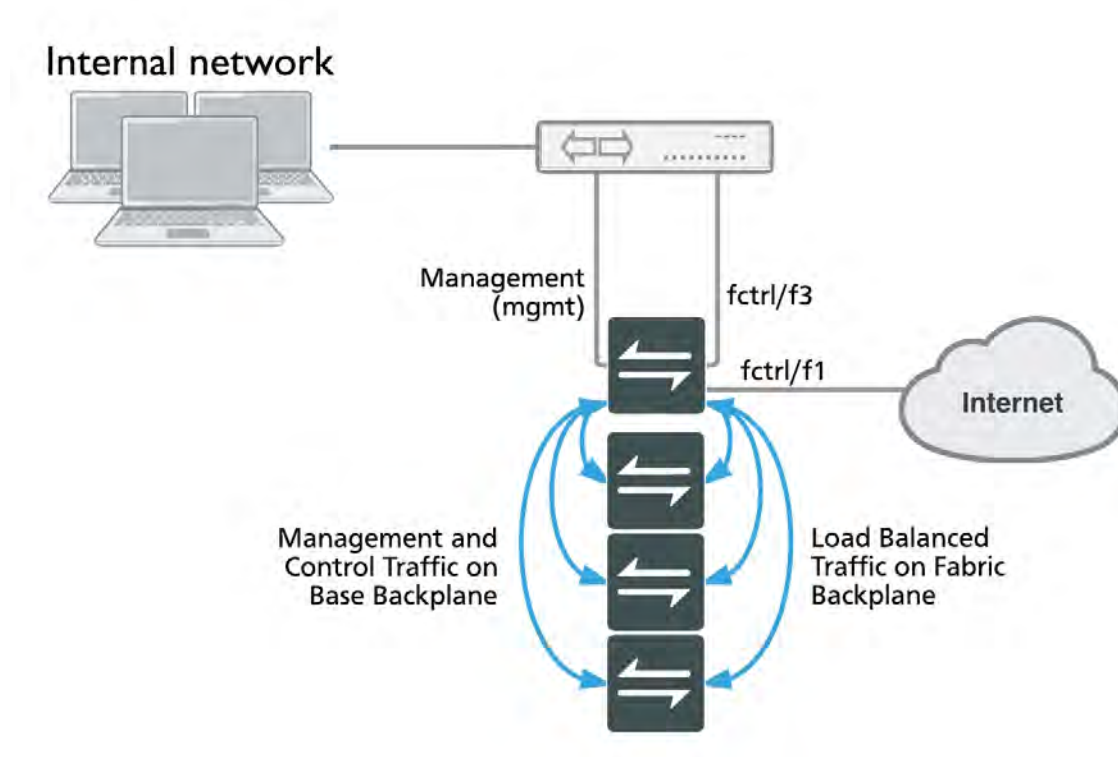

```
diagnose fmnetwork interface list
```

SLBC - Session-aware Load Balancing Cluster

The Session-aware Load Balancing Cluster (SLBC) protocol is used for clusters consisting of FortiControllers that perform load balancing of both TCP and UDP sessions. As session-aware load balancers, FortiControllers, with FortiASIC DP processors, are capable of directing any TCP or UDP session to any worker installed in the same chassis. It also means that more complex networking features such as NAT, fragmented packets, complex UDP protocols and others such as Session Initiation Protocol (SIP), a communications protocol for signaling and controlling multimedia communication sessions, can be load balanced by the cluster.

Currently, only three FortiController models are available for SLBC: FortiController-5103B, FortiController-5903C, and FortiController-5913C. Supported workers include the FortiGate-5001B, 5001C, 5101C, and 5001D.

FortiGate-7000 series products also support SLBC.

You cannot mix FGCP and SLBC clusters in the same chassis.

An SLBC with two FortiControllers can operate in active-passive mode or dual mode. In active-passive mode, if the active FortiController fails, traffic is transferred to the backup FortiController. In dual mode both FortiControllers load balance traffic and twice as many network interfaces are available.

SLBC clusters consisting of more than one FortiController use the following types of communication between FortiControllers to operate normally:

- **Heartbeat:** Allows the FortiControllers in the cluster to find each other and share status information. If a FortiController stops sending heartbeat packets it is considered down by other cluster members. By default heartbeat traffic uses VLAN 999.
- **Base control:** Communication between FortiControllers on subnet 10.101.11.0/255.255.255.0 using VLAN 301.
- **Base management:** Communication between FortiControllers on subnet 10.101.10.0/255.255.255.0 using VLAN 101.
- **Session synchronization:** If one FortiController fails, session synchronization allows another to take its place and maintain active communication sessions. FortiController-5103B session sync traffic uses VLAN 2000. FortiController-5903C and FortiController-5913C session sync traffic between the FortiControllers in slot 1 uses VLAN 1900 and between the FortiControllers in slot 2 uses VLAN 1901. You cannot change these VLANs.

Note that SLBC does not support session synchronization between workers in the same chassis. The FortiControllers in a cluster keep track of the status of the workers in their chassis and load balance sessions to the workers. If a worker fails the FortiController detects the failure and stops load balancing sessions to that worker. The sessions that the worker is processing when it fails are lost.

Changing the heartbeat VLAN

To change the VLAN from the FortiController GUI, from the **System Information** dashboard widget, beside **HA Status**, select **Configure**. Change the **VLAN to use for HA heartbeat traffic(1-4094)** setting.

You can also change the heartbeat VLAN ID from the FortiController CLI. For example, to change the heartbeat VLAN ID to **333**, enter the following:

```
config system ha
    set hbdev-vlan-id 333
end
```

Setting the mgmt interface as a heartbeat interface

To add the mgmt interface to the list of heartbeat interfaces used, on the FortiController-5103B, enter the following:

```
config system ha
    set hbdev b1 b2 mgmt
end
```

This example adds the mgmt interface for heartbeats to the B1 and B2 interfaces. The B1 and B2 ports are recommended because they are 10G ports and the Mgmt interface is a 100Mb interface.

FortiController-5103B is currently the only model that allows its mgmt interface to be added to the heartbeat interfaces list.

Changing the heartbeat interface mode

By default, only the first heartbeat interface (usually B1) is used for heartbeat traffic. If this interface fails on any of the FortiControllers in a cluster, then the second heartbeat interface is used (B2).

To simultaneously use all heartbeat interfaces for heartbeat traffic, enter the following command:

```
config load-balance-setting
    set base-mgmt-interface-mode active-active
end
```

Changing the base control subnet and VLAN

You can change the base control subnet and VLAN from the FortiController CLI. For example, to change the base control subnet to **10.122.11.0/255.255.255.0** and the VLAN ID to **320**, enter the following:

```
config load-balance setting
  set base-ctrl-network 10.122.11.0 255.255.255.0
  config base-ctrl-interfaces
    edit b1
      set vlan-id 320
    next
    edit b2
      set vlan-id 320
  end
```

Changing the base management subnet and VLAN

You can change the base management subnet from the FortiController GUI under **Load Balance > Config** and changing the **Internal Management Network**.

You can also change the base management subnet and VLAN ID from the FortiController CLI. For example, to change the base management subnet to **10.121.10.0/255.255.255.0** and the VLAN to **131**, enter the following:

```
config load-balance setting
  set base-mgmt-internal-network 10.121.10.0 255.255.255.0
  config base-mgt-interfaces
    edit b1
      set vlan-id 131
    next
    edit b2
      set vlan-id 131
  end
```

If required, you can use different VLAN IDs for the B1 and B2 interface.

Changing this VLAN only changes the VLAN used for base management traffic between chassis. Within a chassis the default VLAN is used.

Enabling and configuring the session sync interface

To enable session synchronization in a two chassis configuration, enter the following command:

```
config load-balance setting
  set session-sync enable
end
```

You will then need to select the interface to use for session sync traffic. The following example sets the FortiController-5103B session sync interface to **F4**:

```
config system ha
  set session-sync-port f4
end
```

The FortiController-5903C and FortiController-5913C use b1 and b2 as the session sync interfaces so no configuration changes are required.

FGCP to SLBC migration

You can convert a FGCP virtual cluster (with VDOMs) to an SLBC cluster. The conversion involves replicating the VDOM, interface, and VLAN configuration of the FGCP cluster on the SLBC cluster primary worker, then backing

up the configuration of each FGCP cluster VDOM. Each of the VDOM configuration files is manually edited to adjust interface names. These modified VDOM configuration files are then restored to the corresponding SLBC cluster primary worker VDOMs.

For this migration to work, the FGCP cluster and the SLBC workers must be running the same firmware version, the VDOMS are enabled on the FGCP cluster, and the SLBC workers have been registered and licensed. However, the FGCP cluster units do not have to be the same model as the SLBC cluster workers.

Only VDOM configurations are migrated. You have to manually configure primary worker management and global settings.

Conversion steps

1. Add VDOM(s) to the SLBC primary worker with names that match those of the FGCP cluster.
2. Map FGCP cluster interface names to SLBC primary worker interface names. For example, you can map the FGCP cluster port1 and port2 interfaces to the SLBC primary worker fctl/f1 and fctl/f2 interfaces. You can also map FGCP cluster interfaces to SLBC trunks, and include aggregate interfaces.
3. Add interfaces to the SLBC primary worker VDOMs according to your mapping. This includes moving SLBC physical interfaces into the appropriate VDOMs, creating aggregate interfaces, and creating SLBC trunks if required.
4. Add VLANs to the SLBC primary worker that match VLANs in the FGCP cluster. They should have the same names as the FGCP VLANs, be added to the corresponding SLBC VDOMs and interfaces, and have the same VLAN IDs.
5. Add inter-VDOM links to the SLBC primary worker that match the FGCP cluster.
6. Backup the configurations of each FGCP cluster VDOM, and SLBC primary worker VDOM.
7. Use a text editor to replace the first four lines of each FGCP cluster VDOM configuration file with the first four lines of the corresponding SLBC primary worker VDOM configuration file. Here are example lines from an SLBC primary worker VDOM configuration file:

```
#config-version=FG-5KB-5.02-FW-build670-150318:opmode=0:vdom=1:user=admin
#conf_file_ver=2306222306838080295
#buildno=0670
#global_vdom=0:vd_name=VDOM1
```
8. With the text editor, edit each FGCP cluster VDOM configuration file and replace all FGCP cluster interface names with the corresponding SLBC worker interface names, according to the mapping you created in step 2.
9. Set up a console connection to the SLBC primary worker to check for errors during the following steps.
10. From the SLBC primary worker, restore each FGCP cluster VDOM configuration file to each corresponding SLBC primary worker VDOM.
11. Check the following on the SLBC primary worker:
 - Make sure `set type fctrl-trunk` is enabled for SLBC trunk interfaces.
 - Enable the global and management VDOM features that you need, including SNMP, logging, connections to FortiManager, FortiAnalyzer, and so on.
 - If there is a FortiController in chassis slot 2, make sure the worker base2 interface status is up.
 - Remove `snmp-index` entries for each interface.
 - Since you can manage the workers from the FortiController you can remove management-related configurations using the worker mgmt1 and mgmt2 interfaces (Logging, SNMP, admin access, etc.) if you are not going to use these interfaces for management.

How to set up SLBC with one FortiController-5103B

This example describes the basics of setting up a Session-aware Load Balancing Cluster (SLBC) that consists of one FortiController-5103B, installed in chassis slot 1, and three FortiGate-5001C workers, installed in chassis slots 3, 4, and 5.

This SLBC configuration can have up to eight 10Gbit network connections.

Configuring the hardware

1. Install a FortiGate-5000 series chassis and connect it to power. Install the FortiController in slot 1. Install the workers in slots 3, 4, and 5. Power on the chassis.
2. Check the chassis, FortiController, and FortiGate LEDs to verify that all components are operating normally. (To check normal operation LED status see the FortiGate-5000 series documents available [here](#).)
3. Check the FortiSwitch-ATCA release notes and install the latest supported firmware on the FortiController and on the workers. Get FortiController firmware from the [Fortinet Support site](#). Select the FortiSwitch-ATCA product.

Configuring the FortiController

To configure the FortiController, you will need to either connect to the FortiController GUI or CLI with the default IP address of `http://192.168.1.99`. Log in using the admin account (no password).

1. Add a password for the admin account. Use the **Administrators** widget in the GUI, or enter the following CLI command:

```
config admin user
  edit admin
    set password <password>
  end
```
2. Change the FortiController mgmt interface IP address. Use the **Management Port** widget in the GUI, or enter the following CLI command:

```
config system interface
  edit mgmt
    set ip 172.20.120.151/24
  end
```
3. If you need to add a default route for the management IP address, enter the following command:

```
config route static
  edit route 1
    set gateway 172.20.121.2
  end
```
4. To set the chassis type that you are using, enter the following CLI command:

```
config system global
  set chassis-type fortigate-5140
end
```
5. Go to **Load Balance > Config** and add workers to the cluster by selecting **Edit** and moving the slots that contain workers to the **Member** list. The Config page shows the slots in which the cluster expects to find workers. Since the workers have not been configured yet, their status is **Down**.
Configure the **External Management IP/Netmask**. Once the workers are connected to the cluster, you can use this IP address to manage and configure them.
6. You can also enter the following CLI command to add slots 3, 4, and 5 to the cluster:

```
config load-balance setting
  config slots
    edit 3
```

```
next
  edit 4
next
  edit 5
end
end
```

7. You can also enter the following command to configure the external management IP/Netmask and management access to the following address:

```
config load-balance setting
  set base-mgmt-external-ip 172.20.120.100 255.255.255.0
  set base-mgmt-allowaccess https ssh ping
end
```

Adding the workers

Before you begin adding workers to the cluster, make sure you enter the `execute factoryreset` command in the CLI so the workers are set to factory default settings. If the workers are going to run FortiOS Carrier, add the FortiOS Carrier licence instead - this will reset the worker to factory default settings.

Also make sure to register and apply licenses to each worker, including FortiClient licensing, FortiCloud activation, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMs). You can also install any third-party certificates on the primary worker before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to all of the workers. FortiToken licenses can be added at any time, which will also synchronize across all of the workers.

1. Log in to each of the worker's CLI and enter the following CLI command to set the worker to operate in FortiController mode:

```
config system elbc
  set mode fortincontroller
end
```

Once the command is entered, the worker restarts and joins the cluster.

2. On the FortiController, go to **Load Balance > Status**. You will see the workers appear in their appropriate slots. The worker in the lowest slot number usually becomes the primary unit.

You can now manage the workers in the same way as you would manage a standalone FortiGate. You can connect to the worker GUI or CLI using the **External Management IP**. If you had configured the worker mgmt1 or mgmt2 interfaces you can also connect to one of these addresses to manage the cluster.

To operate the cluster, connect networks to the FortiController front panel interfaces and connect to a worker GUI or CLI to configure the workers to process the traffic they receive. When you connect to the External Management IP you connect to the primary worker. When you make configuration changes they are synchronized to all workers in the cluster.

Managing the devices in an SLBC with the external management IP

The External Management IP address is used to manage all of the individual devices in a SLBC by adding a special port number. This special port number begins with the standard port number for the protocol you are using and is followed by two digits that identify the chassis number and slot number. The port number can be calculated using the following formula:

$$\text{service_port} \times 100 + (\text{chassis_id} - 1) \times 20 + \text{slot_id}$$

Where:

- **service_port** is the normal port number for the management service (80 for HTTP, 443 for HTTPS and so on).
- **chassis_id** is the chassis ID specified as part of the FortiController HA configuration and can be 1 or 2.
- **slot_id** is the number of the chassis slot.

By default, chassis 1 is the primary chassis and chassis 2 is the backup chassis. However, the actual primary chassis is the one with the primary FortiController, which can be changed independently of the chassis number. Additionally, the **chassis_id** is defined by the chassis number, *not* whether the chassis contains the primary FortiController.

Some examples:

- HTTPS, chassis 1, slot 2: $443 \times 100 + (1 - 1) \times 20 + 2 = 44300 + 0 + 2 = 44302$:
browse to: <https://172.20.120.100:44302>
- HTTP, chassis 2, slot 4: $80 \times 100 + (2 - 1) \times 20 + 4 = 8000 + 20 + 4 = 8024$:
browse to <http://172.20.120.100/8024>
- HTTPS, chassis 1, slot 10: $443 \times 100 + (1 - 1) \times 20 + 10 = 44300 + 0 + 10 = 44310$:
browse to <https://172.20.120.100/44310>

Single chassis or chassis 1 special management port numbers

Slot number	HTTP (80)	HTTPS (443)	Telnet (23)	SSH (22)	SNMP (161)
Slot 1	8001	44301	2301	2201	16101
Slot 2	8002	44302	2302	2202	16102

Slot 14	8034	44334	2334	2234	16134

For more detailed information regarding FortiController SLBC configurations, see the [FortiController documentation](#).

Fortinet Security Fabric

Security Fabric spans across an entire network linking different security sensors and tools together to collect, coordinate, and respond to malicious behavior in real time. Security Fabric can be used to coordinate the behavior of different Fortinet products in your network, including FortiGate, FortiAnalyzer, FortiClient, FortiSandbox, FortiAP, FortiSwitch, and FortiClient Enterprise Management Server (EMS). Security Fabric supports FortiOS 5.4.1+, FortiSwitchOS 3.3+, and FortiClient 5.4.1+.

Port TCP/8009 is the port FortiGate uses for incoming traffic from the FortiClient Portal, as user information (such as IP address, MAC address, avatar, and other profile information) is automatically synchronized to the FortiGate and EMS.

The brief example below assumes that FortiTelemetry has been enabled on the top-level FortiGate (**FGT1**), OSPF routing has been configured, and that policies have been created for all FortiGate units to access the Internet.

For more details on how to configure a security fabric between FortiGate units, see [Fortinet Security Fabric installation](#) on the Fortinet Cookbook website.

Enabling Security Fabric on the FortiGate:

1. On the upstream FortiGate (FGT1), go to **Security Fabric > Settings** and enable **FortiGate Telemetry**.
2. Enter a **Group name** and **Group password** for the fabric.

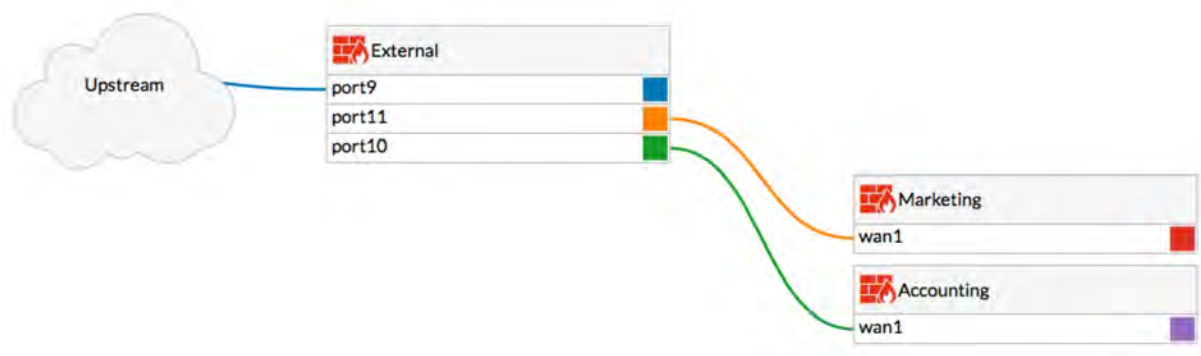

3. On a downstream FortiGate (such as FGT2 or FGT3), configure the same fabric settings as were set on FGT1.
4. Enable **Connect to upstream FortiGate**.
Be sure you do *not* enable this on the topmost-level FortiGate (in this example, FGT1).
5. In **FortiGate IP**, enter the FGT1 interface that has **FortiTelemetry** enabled. The **FortiTelemetry port** (set to **8013**) can be changed as required.

Once set up, you can view your network's Security Fabric configuration under **FortiView** through two topology dashboards.

6. On top-level FortiGate, go to **Security Fabric > Physical Topology**. This dashboard shows a visualization of all access layer devices in the fabric.

7. Go to **Security Fabric > Logical Topology** to view information about the interfaces (logical or physical) that each device in the fabric is connected to.

Other Security Fabric configurations for your network are available through the Fortinet Cookbook [Security Fabric Collection](#) page.

FortiTelemetry/On-Net/FortiClient Endpoint Compliance

FortiTelemetry (called FortiHeartBeat in FortiOS 5.4.0 and FortiClient Access in FortiOS 5.2) is an interface option that listens for connections from devices with FortiClient installed.

FortiTelemetry is the TCP/8013 protocol used between FortiClient and FortiGate, FortiClient and FortiClient EMS, and between FortiGate and other FortiGates in CSF configurations.

While all GUI references of FortiHeartBeat have been changed to FortiTelemetry in FortiOS 5.4.1, the CLI options have *not* been renamed and will remain as `fortiheartbeat`.

With FortiTelemetry enabled on the FortiGate, you can enforce FortiTelemetry for all FortiClients. This FortiClient endpoint compliance will require all clients to have FortiClient installed in order to get access through the FortiGate. Configure these settings in the internal interface under **Network > Interfaces**. Edit the interface of your choice. Under **Restrict Access > Administrative Access**, enable **FortiTelemetry**, then enable **FortiClient On-Net Status**.

CLI command - To enable FortiTelemetry on an interface:

```
config system interface edit <port_number>
    set listen-forticlient-connection enable
    set endpoint-compliance enable
end
```

You can also enable **DHCP server** and **FortiClient On-Net Status** to display the on-net status of FortiClient devices on the FortiClient Monitor (under **Monitor > FortiClient Monitor**).

CLI command - To enable FortiClient On-Net status for a DHCP server added to the port1 interface:

```
config system dhcp server edit 1
    set interface port1
    set forticlient-on-net-status enable
end
```

FortiClient endpoint licence updates

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum (forum.fortinet.com). Phone support is only available for paid licenses.

Model(s)	Maximum client limit
VM00	200
FGT/FWF 30 to 90 series	200

Model(s)	Maximum client limit
FGT 100 to 400 series	600
FGT 500 to 900 series, VM01, VM02	2,000
FGT 1000 to 2900 series	20,000
FGT 3000 to 3600 series, VM04	50,000
FGT 3700D and above, VM08 and above	100,000

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

Connecting FortiClient Telemetry after installation

After FortiClient is installed on an endpoint, FortiClient automatically launches and searches for a FortiGate or FortiClient EMS for FortiClient Telemetry connection. When FortiClient locates a FortiGate or EMS, the **FortiGate Detected** or **Enterprise Management Server (EMS) Detected** dialog box will appear:

If all the information displayed is correct, select **Accept**. FortiClient Telemetry will connect to the identified FortiGate/EMS.

Alternately, you can select **Cancel** and launch FortiClient without connecting to FortiClient Telemetry. This will launch FortiClient in standalone mode, where you can manually connect FortiClient Telemetry.

After FortiClient Telemetry is connected to FortiGate or EMS, FortiClient downloads a profile from FortiGate/EMS.

How FortiClient locates FortiGate/EMS

FortiClient uses the following methods in the following order to automatically locate FortiGate/EMS for Telemetry connection:

1. **Telemetry gateway IP list:** FortiClient Telemetry searches for IP addresses in its subnet in the Gateway IP list. It connects to the FortiGate in the list that is also in the same subnet as the host system.
If FortiClient cannot find any FortiGates in its subnet, it will attempt to connect to the first reachable FortiGate in the list, starting from the top. The order of the list is maintained as it was configured in the Gateway IP list.
2. **Remembered gateway IP list:** You can configure FortiClient to remember gateway IP addresses when you connect Telemetry to FortiGate/EMS. Later FortiClient can use the remembered IP addresses to automatically connect Telemetry to FortiGate/EMS.
3. **Default gateway IP address:** The default gateway IP address is specified on the FortiClient endpoint and is used to automatically connect to FortiGate. This method does not support connection to EMS.

FortiClient obtains the default gateway IP address from the operating system on the endpoint device. The default gateway IP address of the endpoint device should be the IP address for the FortiGate interface with Telemetry enabled.

If FortiClient is unable to automatically locate a FortiGate/EMS on the network for Telemetry connection, you can type the gateway IP address of the FortiGate/EMS.

FortiClient uses the same process to connect Telemetry to FortiGate/EMS after the FortiClient endpoint reboots, rejoins the network, or encounters a network change.

FortiGuard

FortiGuard services can be purchased and registered to your FortiGate unit. The FortiGate must be connected to the Internet in order to automatically connect to the FortiGuard Distribution Network (FDN) to validate the license and download FDN updates.

The FortiGuard subscription update services include:

- AntiVirus (AV)
- Intrusion Protection Service (IPS)
- Application Control
- Anti-Spam
- Web Filtering
- Web Application Firewall (WAF)

The FDN sends notice that a FortiGuard AntiVirus and IPS update is available on UDP/9443.

The following information concerns certain considerations in regards to FortiGate receiving FortiGuard updates through FDN, how the submission of malware statistics to FortiGuard is handled, an automatic update behaviour when FortiGate has expired licenses, and related CLI commands.

Enabling FDN updates and FortiGuard services

In order to receive FortiGuard subscription updates, the unit needs to have access to the Internet and be able to connect to a DNS server in order to resolve the following URLs:

- **update.fortiguard.net:** For AV and IPS updates
 - **service.fortiguard.net:** For web filtering and anti-spam updates
 - **support.fortinet.com**
1. Go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**, and configure an update schedule.
 2. You can force the unit to connect to the AV/IPS server by selecting **Update AV & IPS Definitions**.
 3. You can view your subscription details above in the **License Information** table.
 4. Once the schedule has been enabled, select **Apply**.

To see if the service is viable, open the CLI console and enter the following commands below.

For Web Filtering:

```
diagnose debug rating
```

For Anti-Spam:

```
diagnose spamfilter fortishield servers
```

If only one or two IPs are displayed in the command outputs, it could be one of the following issues:

- **No response from the DNS server:** Either the DNS server is unreachable or there is a problem with the routing. Make sure that contact to the DNS server is available by resolving some URLs from the CLI, for example:

```
execute ping www.google.com
execute ping service.fortiguard.net
```

You can also

- **Review update errors:** Review update information from the last update, enable debug outputs and force the update:

```
diagnose test update info
diagnose debug enable
diagnose debug application update 255
execute update-ase
execute update-av
execute update-ips
```

After troubleshooting, it is highly recommended to turn off debug mode:

```
diagnose debug disable
diagnose debug application update 0
```

- **FortiGuard Web filtering:** Port blocking or packet inspection is occurring downstream. The default port used by the FortiGuard for the FortiGuard services is 8888.

You can change this port using the following command:

```
config system fortiguard
    set port <port_number>
end
```

You can also change the source port for management traffic with the following CLI command:

```
config system global
    set ip-src-port-range 1035-25000
end
diagnose test application urlfilter 99
diagnose test application smtp 99
```

Submission of malware statistics to FortiGuard

FortiGates periodically send encrypted AntiVirus, IPS, and Application Control event statistics to FortiGuard. Included with these malware statistics is the IP address and serial number of the FortiGate and the country in which the FortiGate is located.

The statistics are used to improve various aspects of FortiGate malware protection. For example, AntiVirus statistics allow FortiGuard to determine the viruses that are active in the wild. Signatures for such viruses are kept in the Active AV Signature Database that is used by many Fortinet products. Signatures for inactive viruses are moved to the Extended/Extreme AV Signature Database used by some customers. If the events for inactive viruses start appearing in malware statistics, these signatures can be moved back to the Active AV Signature Database.

The FortiGate and FortiGuard servers go through a 2-way SSL/TLS 1.2 authentication before any data is transmitted. The certificates used in this process must be trusted by each other and signed by Fortinet CA server.

Malware statistics are accumulated and sent periodically (by default every 60 minutes).

Fortinet products can only accept data from authorized FortiGuard servers. Fortinet products use DNS to find FortiGuard servers and periodically update their FortiGate server list. All other servers are provided by a list that is updated through the encrypted channel.

The submission of malware data is in accordance with Fortinet's "Automatically-Collected Information" detailed in the [Fortinet Privacy Policy](#), and the purpose of this collection is outlined in the "Use of your Information" section of the privacy policy.

There is no sensitive or personal information included in these submissions. Only malware statistics are sent.

Fortinet uses the malware statistics collected in this manner to improve the performance of the FortiGate services and to display statistics on Fortinet's Support site for customers registered FortiGate devices.

Fortinet may also publish or share statistics or results derived from this malware data with various audiences. The malware statistics shared in this way do not include any customer data.

To enable, disable, and/or customize how often statistics are sent to FortiGuard, use the following command:

CLI syntax

```
config system global
  set fds-statistics {enable | disable}
  set fds-statistics-period <minutes>
end
```

In addition to secure submission of statistics to FortiGuard, there are other mechanisms in place to prevent unauthorized FortiGuard updates from clients:

- The server certificate has to be authenticated by FortiGates, and it only trusts Fortinet's root certificate.
- Proprietary encryption (including FCP, an application-level proprietary protocol) that only Fortinet's own servers/devices can prepare.

FortiGates can only accept data from Fortinet's own list of servers, although the list can be updated through previously connected servers. DNS is used on the initial server, but all other servers are provided by a list that is updated through SSL, meaning that only FortiGates accept data from those servers.

Automatic update at every GUI login

FortiGates running FortiOS 5.6.1 and above may perform automatic "update now" updates when one of the "core" licenses is unavailable: Application Control, IPS, or AntiVirus. Please note that this automatic update is triggered even if the following CLI command is set:

```
config system autoupdate schedule
  set status disable
end
```

CLI syntax

The following section contains commands to control FortiGuard.

system autoupdate push-update

The following command will set the FDN push update port.

```
config system.autoupdate push-update
  set port <integer>
end
```

system autoupdate tunneling

The following command will set the proxy server port that the FortiGate will use to connect to the FortiGuard Distribution Network (FDN).

```
config system.autoupdate tunneling
    set port <integer>
end
```

system fortiguard

The following command will set the port by which scheduled FortiGuard service updates will be received.

```
config system fortiguard
    set port {53 | 8888 | 80}
end
```

webfilter fortiguard

The following command will close ports used for HTTPS/HTTP override authentication and disable user overrides:

```
config webfilter fortiguard
    set close-ports {enable | disable}
end
```

For more information, including FortiGuard execute commands used to manage FortiCloud domains and operations, see the [CLI Reference](#).

FortiLink

FortiGate units can be used to remotely manage FortiSwitch units, which is also known as using a FortiSwitch in FortiLink mode. FortiLink defines the management interface and the remote management protocol between the FortiGate and FortiSwitch.

Different FortiGate models support remote management for varying numbers of FortiSwitches, as shown below:

FortiGate	Number of FortiSwitches
Up to FortiGate 98 and FortiGate VM01	8
FortiGate 100 to 280 and FortiGate VM02	24
FortiGate 300 to 5xx	48
FortiGate 600 to 900 and FortiGate VM04	64
FortiGate 1000 and up	128
FortiGate-3000 and up, and FortiGate VM08 and up	256

Supported FortiSwitch models

The following table shows the FortiSwitch models that support FortiLink mode when paired with the corresponding FortiGate models and the listed minimum software releases.

FortiSwitch	FortiGate	Earliest FortiSwitchOS	Earliest FortiOS
FS-224D-POE	FGT-90D (Wifi/POE)	3.0.0	5.2.2
FS-108D-POE	FGT-60D (all)	3.0.1	5.2.3
FSR-112D-POE	FGR-90D	3.0.1	5.2.3
FS-124D	FGT-90D + FGT-60D	3.0.1	5.2.3
FS-124D-POE	FGT-90D + FGT-60D	3.0.1	5.2.3
FS-224D-FPOE	FGT-90D + FGT-60D	3.0.1	5.2.3

Note that **all** FortiSwitches above also support FortiLink mode when paired with the following FortiGate models: 100D, 140D (POE, T1), 200D, 240D, 280D (POE), 600C, 800C, and 1000C.

FortiLink ports for each FortiSwitch model

Each FortiSwitch model provides one designated port for the FortiLink connection. The table below lists the FortiLink port for each model:

FortiSwitch model	Port for FortiLink connection
FS-28C	WAN port 1
FS-324B-POE	Management Port
FS-448B (10G only)	WAN port (uplink 1)
FS-348B	Last port (port 48)
For all D-series switches, use the last (highest number) port for FortiLink. For example:	
FS-108D-POE	Last port (port 10)
FSR-112D-POE	Last port (port 12)
FS-124D	Last port (port 26). May require an SFP module.*
FS-224D-POE	Last port (port 24)
FS-224D-FPOE	Last port (port 28). May require an SFP module.*

* FortiSwitch 3.3.1 and later releases support the use of an RJ-45 port for FortiLink. Please contact [Fortinet Customer Service & Support](#) for additional information.

FortiLink ports for each FortiGate model

The following table shows the ports for each model of FortiGate that can be FortiLink-dedicated.

FortiGate model	Port for FortiLink connection
FGT-90D, FGT-90D-POE, FWF-90D, FWF-90D-POE	port1 - port14
FGT-60D, FGT-60D-POE, FWF-60D, FWF-60D-POE	port1 - port7
FGT-100D	port1 - port16
FGT-140D , 140D-POE, 140D-POE-T1	port1 - port36
FGT-200D	port1 - port16
FGT-240D	port1 - port40
FGT-280D, FGT-280D-POE	port1 - port84
FGT-600C	port3 - port22

FortiGate model	Port for FortiLink connection
FGT-800C	port3 - port24
FGT-1000C	port3 - port14, port23, port24

Auto-discovery of the FortiSwitch ports

In releases FortiSwitchOS 3.3.0 and beyond, the D-series FortiSwitch models support FortiLink auto-discovery, which is automatic detection of the port connected to the FortiGate.

You can use any of the switch ports for FortiLink. Use the following FortiSwitch CLI commands to configure a port for FortiLink auto-discovery:

```
config switch interface
edit <port>
set auto-discovery-fortilink enable
end
```

Note that some FortiSwitch ports are enabled for auto-discovery by default.

Each FortiSwitch model provides a set of ports that are enabled for FortiLink auto-discovery by default. If you connect the FortiLink using one of these ports, no switch configuration is required.

In general (in FortiSwitchOS 3.4.0 and later releases), the last four ports are the default auto-discovery FortiLink ports. The table below lists the default auto-discovery ports for each switch model:

FortiSwitch model	Default auto-FortiLink ports
FS-108D	ports 9 and 10
FSR-112D	ports 9, 10, 11, and 12
FS-124D, FS-124D-POE	ports 23, 24, 25, and 26
FS-224D-POE	ports 21, 22, 23, and 24
FS-224D-FPOE	ports 25, 26, 27, and 28
FS-248D-POE	ports 49, 50, 51, and 52
FS-248D-FPOE	ports 49, 50, 51, and 52
FS-424D, FS-424D-POE, FS-424D-FPOE	ports 25 and 26
FS-448D, FS-448D-POE, FS-448D-FPOE	ports 49, 50, 51, and 52
FS-524D, FS-524D-FPOE	ports 25, 26, 27, 28, 29, and 30
FS-548D, FS-548D-FPOE	ports 49, 50, 51, 52, 53, and 54
FS-1024D, FS-1048D, FS-3032D	all ports

You can also run the `show switch interface` CLI command on the FortiSwitch to see the ports that have auto-discovery enabled.

Adding a managed FortiSwitch to the FortiGate

The following steps show how to add a new managed FortiSwitch using the FortiGate GUI or the CLI.

For FortiSwitchOS releases prior to 3.3.0, you must [Set the FortiSwitch to remote management mode](#) before following the steps below.

Using the FortiGate GUI:

1. Connect a cable from the designated FortiSwitch port to an unused port on the FortiGate. Refer to [FortiLink ports for each FortiSwitch model](#) for additional information.
2. Go to Network > Interfaces and edit an internal port on the FortiGate.
3. Set **Addressing mode** to **Dedicated to FortiSwitch** and select **OK**.
4. As of FortiOS 5.4.0, the **Managed FortiSwitch** GUI option can only be accessed by enabling it through the CLI console.

Open the CLI console and enter the following command to make the switch controller available in the GUI, and to set the reserved subnetwork for the controller:

```
config system global
    set switch-controller enable
    set switch-controller-reserved-network 169.254.254.0 255.255.255.0
end
```

5. Go to **WiFi & Switch Controller > Managed FortiSwitch**. The new FortiSwitch should now be displayed in the table.
6. Right-click on the FortiSwitch and select **Authorize**.

Using the FortiGate CLI:

Note that, for the example shown below, the FortiGate's port1 is configured as the FortiLink port.

1. If required, remove port1 from the **lan** interface:

```
config system virtual-switch
    edit lan
        config port
            delete port1
        end
    end
end
```

2. Configure the interface for port1:

```
config system interface
    edit port1
        set ip 172.20.120.10 255.255.255.0
        set allowaccess capwap
        set vlanforward enable
    end
end
```

3. Configure an NTP server on port1:

```
config system ntp
```

```

    set server-mode enable
    set interface port1
end

```

4. Authorize the FortiSwitch unit as a managed switch (note that that FortiSwitch will reboot once you issue the command below):

```

config switch-controller managed-switch
    edit FS224D3W14000370
        set fsw-wan1-admin enable
    end
end

```

5. Configure a DHCP server on port1:

```

config system dhcp server
    edit 0
        set netmask 255.255.255.252
        set interface port1
        config ip-range
            edit 0
                set start-ip 169.254.254.2
                set end-ip 169.254.254.50
            end
        set vci-match enable
        set vci-string FortiSwitch
        set ntp-service local
    end
end

```

Set the FortiSwitch to remote management mode

Use the FortiSwitch GUI or the CLI to set the remote management mode.

Note that the following steps are not necessary for FortiSwitchOS releases 3.3.0 or later.

Using the FortiSwitch GUI:

1. Go to **System > Dashboard > Status** and locate the **System Information** widget.
2. Beside **Operation Mode**, select **Change**.
3. Change **Management Mode** to **FortiGate Remote Management** and select **OK**.
4. A warning will appear asking if you wish to continue. Select **OK**.

Using the FortiSwitch CLI:

```

config system global
    set switch-mgmt-mode fortilink
end

```

Configuring the FortiSwitch remote management port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

To do this, from the FortiSwitch CLI, enter the following command:

```

config router static
    edit 1

```

```
    set device mgmt
    set gateway <router_IP_address>
    set dst <router_subnet> <subnet_mask>
end
end
```

Configuring FortiLink LAG

Starting with FortiOS 5.4.0 and FortiSwitchOS 3.3.0, you can configure the Fortilink as a Link Aggregation Group (LAG) to provide increased bandwidth between the FortiGate and FortiSwitch.

Connect any two ports on the FortiGate to two ports on the FortiSwitch. Make sure that you use the designated Fortilink port as one of the ports on the switch.

To configure the Fortilink as a LAG on the FortiGate, create a trunk (of type fortilink) with the two ports that you connected to the switch:

```
config system interface
    edit "fortilink"
        set vdom root
        set allowaccess ping capwap http https
        set type fortilink
        set member port4 port5
        set snmp-index 17
        set lacp-mode static
    next
end
config system ntp
    set ntpsync enable
    set syncinterval 60
    set server-mode enable
    set interface "fortilink"
end
```

There is no specific configuration required for the LAG on the switch.

FortiOS WAN optimization

Multi-location organizations or businesses using the cloud can provide license-free WAN optimization using FortiOS.

WAN Optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwidth management and unmatched consolidated security performance. WAN optimization reduces your network overhead and removes unnecessary traffic for a better overall performance experience. Efficient use of bandwidth and better application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 GB of internal flash storage.

WAN optimization tunnels use port 7810.

The following features below are available through WAN optimization:

Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth, high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

CIFS, for example, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk's arrival and acknowledgment before sending the next chunk. This large amount of requests and acknowledgements of traffic can delay transfers. WAN Optimization removes this complexity and improves the efficiency of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

Regular bandwidth usage**Improved bandwidth usage with FortiGate protocol optimization****Byte caching**

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

Byte caching breaks large units of application data, such as email attachments or file downloads, into smaller chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user requests a file, WAN optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading the chunks it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption.

Byte caching is not application specific, and assists by accelerating all protocols supported by WAN optimization.

Web caching

WAN optimization reduces download times of content from central files repositories through web caching. FortiOS Web caching stores remote files and web pages on local FortiGate devices for easy local access to commonly accessed files. There is little impact on the WAN, resulting in reduced latency for those requesting the files.

In addition, web caching also recognizes requests for Windows or MS Office updates, and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users, and all subsequent requests for this update are rapidly downloaded from the cache.

Traffic shaping

Controls data flow for specific applications, giving administrators the flexibility to choose which applications take precedence over the WAN. A common use case of traffic shaping would be to prevent one protocol or application from flooding a link over other protocols deemed more important by the administrator.

SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

Explicit web proxy server

Allows users on the internal network to browse the Internet through the explicit web proxy server.

Explicit FTP proxy server

Allows users on the internal network to access FTP servers through the explicit FTP proxy server.

Reverse proxy

The web and FTP proxies can be configured to protect access to web or FTP servers that are behind the FortiGate using a reverse proxy configuration. Reverse proxies retrieve resources on behalf of a client from one or more servers. These resources are then returned to the client as if they originated from the proxy server.

WCCP

The Web Cache Communication Protocol (WCCP) allows you to offload web caching to redundant web caching servers. This traffic redirection helps to improve response time and optimize network resource usage.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

Configuring an explicit proxy with WAN optimization web caching

For this configuration, all devices on the wireless network will be required to connect to the proxy at port 8080 before they can browse the Internet. WAN optimization web caching is added to reduce the amount of Internet bandwidth used and improve web browsing performance.

Enabling WAN optimization and configuring the explicit web proxy for the wireless interface

1. Go to **System > Config > Features**. Ensure that **Explicit Proxy** and **WAN Opt & Cache** are enabled.
2. Go to **System > Network > Interfaces**, edit the wireless interface and select **Enable Explicit Web Proxy**.
3. Go to **System > Network > Explicit Proxy**. Select **Enable Explicit Web Proxy for HTTP/HTTPS**. Make sure that **Default Firewall Policy Action** is set to **Deny**.

Adding an explicit web proxy policy

1. Go to **Policy & Objects > Policy > Explicit Proxy** and create a new policy.
2. Set **Explicit Proxy Type** to **Web** and the **Outgoing Interface** to the Internet-facing interface.
3. Enable **Web Cache**.

Configuring devices on the wireless network to use the web proxy

To use the web proxy, all devices on the wireless network must be configured to use the explicit proxy server. The IP address of the server is the IP address of the FortiGate's wireless interface (for example, 10.10.80.1) and the port is 8080. Some browsers may have to be configured to use the device's proxy settings.

For Windows Vista/7/8, open **Internet Properties**. Go to **Connections > LAN Settings** and enable and configure the **Proxy Server**.

For Mac OS X, open **Network Preferences > Wi-Fi > Advanced > Proxies**. Select **Web Proxy (HTTP)** and configure the proxy settings.

For iOS, go to **Settings > Wi-Fi**. Edit the wireless network. Scroll down to **HTTP PROXY**, select **Manual**, and configure the proxy settings.

For Android, in WiFi network connection settings, edit the wireless network. Select **Show advanced options**, configure a **Manual** proxy, and enter the proxy settings.

Force HTTP and HTTPS traffic to use the web proxy

Block HTTP and HTTPS access to the Internet from the wireless network so that the only path to the Internet is through the explicit proxy. You can edit or delete policies that allow HTTP or HTTPS access. You can also add a policy to the top of the list that **Denies** HTTP and HTTPS traffic.

FSSO - Fortinet Single Sign-On

Fortinet Single Sign-On (FSSO), formerly known as FortiGate Server Authentication Extension (FSAE), is the authentication protocol by which users can transparently authenticate to FortiGate, FortiAuthenticator, and FortiCache devices. The FortiAuthenticator unit identifies users based on their authentication from a different system, and can be authenticated via numerous methods:

- Users can authenticate through a web portal and a set of embeddable widgets.
- Users with FortiClient Endpoint Security installed can be automatically authenticated through the FortiClient SSO Mobility Agent.
- Users authenticating against Active Directory can be automatically authenticated.
- RADIUS Accounting packets can be used to trigger an FSSO authentication.
- Users can be identified through the FortiAuthenticator API. This is useful for integration with third-party systems.

Below are the TCP/UDP ports used by the multiple FSSO modes:

Purpose	Protocol/Port
LDAP group membership lookup (Global Catalog)	TCP/3268
LDAP domain controller discovery and group membership lookup	TCP/389
DC Agent keepalive and push logon info to CA	UDP/8002
CA keepalive and push logon info to Fortigate	TCP/8000
NTLM	TCP/8000
CA DNS	UDP/53
Workstation check, polling mode (preferred method)	TCP/445
Workstation check, polling mode (fallback method)	TCP/135, TCP/139, UDP/137
Remote access to logon events	TCP/445
Group lookup using LDAP	TCP/389
Group lookup using LDAP with global catalog	TCP/3268
Group lookup using LDAPS	TCP/636
Resolve FSSO server name	UDP/53

Configuring the FortiAuthenticator

The FortiAuthenticator unit can be integrated with external network authentication systems, such as RADIUS, LDAP, Windows AD, and FortiClients to poll user logon information and send it to the FortiGate unit.

To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave **Listening port** set to **8000**, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall. Optionally, you can set the **Login expiry** time (default is **480** minutes, or eight hours). This is the length of time users can remain logged in before the system logs them off automatically.
3. Select **Enable authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter the following information:

Enable Windows event log polling (e.g. domain controllers/Exchange servers)	Select for integration with Windows Active Directory
Enable RADIUS Accounting SSO clients	Select if you want to use a Remote RADIUS server.
Enable Syslog SSO	Select for integration with Syslog server.
Enable FortiClient SSO Mobility Agent Service	<p>Once enabled, also select Enable authentication to enable SSO by clients running FortiClient Endpoint Security.</p> <p>Enter the Secret key. Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.</p>

5. Select **OK**.

Configuring the FortiGate

The FortiAuthenticator unit needs to be added to the FortiGate as an SSO agent that will provide user login information.

To add a FortiAuthenticator unit as SSO agent:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. Set **Type** to **Fortinet Single-Sign-On Agent**, and enter a **Name**.
3. In **Primary Agent IP/Name**, enter the IP address of the FortiAuthenticator unit or a name.
4. In **Password**, enter the same secret key defined earlier on the FortiAuthenticator (under **Fortinet SSO Methods > SSO > General**).
5. You may also specify **Users/Groups** from the dropdown menu.
6. Select **OK**.

In a few minutes, the FortiGate unit receives a list of user groups from the FortiAuthenticator unit. When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

FSSO user groups

You can only use FortiAuthenticator SSO user groups directly in identity-based security policies. You must create an FSSO user group, then add FortiAuthenticator SSO user groups to it. These FortiGate FSSO user groups will

then become available for selection in identity-based security policies.

To create an FSSO user group:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. Set **Type** to **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**. The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

Configuring the FortiClient SSO Mobility Agent

In order for the user to successfully set up the SSO Mobility Agent in FortiClient, they must know the FortiAuthenticator IP address and pre-shared key/secret.

To configure FortiClient SSO Mobility Agent:

1. In FortiClient, go to **File > Settings**.
2. Under **Advanced**, select **Enable Single Sign-On mobility agent**.
3. In **Server address**, enter the IP address of the FortiAuthenticator.
4. In **Customize port**, enter the listening port number specified on the FortiAuthenticator unit. You can omit the port number if it is **8005**.
5. Enter the **Pre-shared key**.
6. Select **OK**.

CLI syntax

The following section contains commands to control FSSO.

user/fsso

The following command will set the server address, port, and password for multiple FSSO agents.

```
config user fsso
  edit <name_str>
    set name <string>
    set [server | server2 | server3 | server4 | server5] <string>
    set [port | port2 | port3 | port4 | port5] <integer>
    set [password | password2 | password3 | password4 | password5] <password>
  end
```

user/fsso-polling

The following command will set the Active Directory server port.

```
config user fsso-polling
  edit <name_str>
    set port <integer>
  end
```

OFTP - Optimized Fabric Transfer Protocol

The Optimized Fabric Transfer Protocol (OFTP) is used when information is synchronized between FortiAnalyzer and FortiGate. Remote logging and archiving can be configured on the FortiGate to send logs to a FortiAnalyzer (and/or FortiManager) unit.

OFTP listens on ports TCP/514 and UDP/514.

You can connect to a FortiAnalyzer unit from a FortiGate unit using Automatic Discovery, so long as both units are on the same network. Connecting these devices in this way does not use OFTP. Instead, the Fortinet Discovery Protocol (FDP) is used to locate the FortiAnalyzer unit.

When you select automatic discovery, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers the FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

CLI command - To connect to FortiAnalyzer using automatic discovery:

```
config log fortianalyzer setting
  set status [enable | disable]
  set server <ip_address>
  set gui-display [enable | disable]
  set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic.

To send logs from FortiGate to FortiAnalyzer:

1. Go to **Log & Report > Log Settings** and enable **Send Logs to FortiAnalyzer/FortiManager** (under **Remote Logging and Archiving**).
2. Enter the FortiAnalyzer unit's IP address in the **IP Address** field provided.
3. For **Upload Option**, select **Store & Upload Logs** to set when the uploads occur (either **Daily**, **Weekly**, or **Monthly**), and the time when the unit uploads the logs. Select **Realtime** to upload logs as they come across the FortiGate unit.
4. Logs sent to FortiAnalyzer can be encrypted by enabling **Encrypt Log Transmission**.

FortiClient EMS - Enterprise Management Server

FortiClient Enterprise Management Server (FortiClient EMS) is a security management solution that enables scalable and centralized management of multiple endpoints (computers). FortiClient EMS provides efficient and effective administration of endpoints running FortiClient. It provides visibility across the network to securely share information and assign security profiles to endpoints. It is designed to maximize operational efficiency and includes automated capabilities for device management and troubleshooting.

FortiClient EMS is designed to meet the needs of small to large enterprises that deploy FortiClient on endpoints. Benefits of deploying FortiClient EMS include:

- Remotely deploying FortiClient software to Windows PCs.
- Updating profiles for endpoint users regardless of access location, such as administering antivirus, web filtering, VPN, and signature updates.
- Administering FortiClient endpoint registrations, such as accepting, deregistering, and blocking registrations.
- Managing endpoints, such as status, system, and signature information.
- Identifying outdated versions of FortiClient software.

Required services

You must ensure that required ports and services are enabled for use by FortiClient EMS and its associated applications on your server. The required ports and services enable FortiClient EMS to communicate with clients and servers running associated applications.

Communication	Service	Protocol	Port
FortiClient endpoint registration	File transfers	TCP	8013 (default)
Computer browser service	Enabled		
Samba (SMB) service <ul style="list-style-type: none">• During FortiClient deployment, endpoints may connect to the FortiClient EMS server using the SMB service.	Enabled		445
Distributed Computing Environment / Remote Procedure Calls (DCE- RPC) <ul style="list-style-type: none">• The FortiClient EMS server connects to the endpoints using RPC for FortiClient deployment.	Enabled		135
Active Directory server connection	When used as a default connection		389
Windows	HTTP	TCP	80

Communication	Service	Protocol	Port
Internet Information Services (IIS)	HTTPS	TCP	443, 10443
SQL server			

For more information about FortiClient EMS, including other requirements, installation, and management, see the [FortiClient EMS documentation](#).

Chapter 12 - FortiWiFi and FortiAP Configuration Guide

FortiAP and FortiWiFi configuration guide

Welcome and thank you for selecting Fortinet products for your network protection. This document describes how to configure wireless networks with FortiWiFi, FortiGate, and FortiAP units.

This chapter contains the following topics:

- [Before you begin](#)
- [How this guide is organized](#)

Before you begin

Before you begin using this guide, please ensure that:

- You have administrative access to the web-based manager and/or CLI.
- The FortiGate unit is integrated into your network.
- The operation mode has been configured.
- The system time, DNS settings, administrator password, and network interfaces have been configured.
- Firmware, FortiGuard Antivirus and FortiGuard Antispam updates are completed.
- FortiGuard Analysis & Management Service is properly configured.

While using the instructions in this guide, note that administrators are assumed to be super_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

How this guide is organized

This FortiOS Handbook chapter contains the following sections:

[Introduction to wireless networking](#) explains the basic concepts of wireless networking and how to plan your wireless network.

[Configuring a WiFi LAN](#) explains how to set up a basic wireless network, prior to deploying access point hardware.

[Access point deployment](#) explains how to deploy access point hardware and add it to your wireless network configuration.

[Wireless Mesh](#) explains how to configure a Wi-Fi network where access points are connected to the Wi-Fi controller wirelessly instead of by Ethernet.

[Combining WiFi and wired networks with a software switch](#) shows how to use the FortiAP Wi-Fi-Ethernet bridge feature.

[Protecting the WiFi Network](#) explains the Wireless Intrusion Detection System (WIDS).

[Wireless network monitoring](#) explains how to monitor your wireless clients and how to monitor other wireless access points, potentially rogues, in your coverage area.

[Configuring wireless network clients](#) explains how to configure typical wireless clients to work with a WPA-Enterprise protected network.

[Wireless network examples](#) provides two examples. The first is a simple Wi-Fi network using automatic configuration. The second is a more complex example of a business with two Wi-Fi networks, one for employees and another for guests or customers.

[Using a FortiWiFi unit as a client](#) explains how to use a FortiWiFi unit as a wireless client to connect to other Wi-Fi networks. This connection can take the place of an Ethernet connection where wired access to a network or to the Internet is not available.

[Support for location-based services](#) explains how Fortinet supports location-based services that collect information about devices near FortiGate-managed access points, even if the devices don't associate with the network.

[Reference](#) provides information about Wi-Fi radio channels.

What's new in FortiOS 5.6

This chapter describes new wireless features added to FortiOS 5.6.

FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

- ["FortiAP LED Blinking" on page 1484](#)
- ["Wireless controller optimization for large deployment - AP image upgrade" on page 1484](#)

FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

Hotspot 2.0

Multiple new CLI commands have been added, under `config wireless-controller`, to configure Hotspot 2.0 Access Network Query Protocol (ANQP), a query and response protocol that defines seamless roaming services offered by an AP.

Syntax

```
config wireless-controller hotspot20 anqp-3gpp-cellular
  edit {name}
    config mcc-mnc-list
      edit {id}
        set id {integer}
        set mcc {string}
        set mnc {string}
      next
    next
  end

config wireless-controller hotspot20 anqp-ip-address-type
  edit {name}
    set ipv6-address-type {option}
    set ipv4-address-type {option}
  next
end

config wireless-controller hotspot20 anqp-nai-realm
  edit {name}
    config nai-list
      edit {name}
        set encoding {enable | disable}
        set nai-realm {string}
        config eap-method
          edit {index}
            set index {integer}
            set method {option}
          config auth-param
```

```
                edit {index}
                    set index {integer}
                    set id {option}
                    set val {option}
                next
            next
        next
    next
end

config wireless-controller hotspot20 anqp-network-auth-type
    edit {name}
        set auth-type {option}
        set url {string}
    next
end

config wireless-controller hotspot20 anqp-roaming-consortium
    edit {name}
        config oi-list
            edit {index}
                set index {integer}
                set oi {string}
                set comment {string}
            next
        next
    next
end

config wireless-controller hotspot20 anqp-venue-name
    edit {name}
        config value-list
            edit {index}
                set index {integer}
                set lang {string}
                set value {string}
            next
        next
    next
end

config wireless-controller hotspot20 h2qp-conn-capability
    edit {name}
        set icmp-port {option}
        set ftp-port {option}
        set ssh-port {option}
        set http-port {option}
        set tls-port {option}
        set pptp-vpn-port {option}
        set voip-tcp-port {option}
        set voip-udp-port {option}
        set ikev2-port {option}
        set ikev2-xx-port {option}
        set esp-port {option}
    next
end

config wireless-controller hotspot20 h2qp-operator-name
    edit {name}
```

```

    config value-list
        edit {index}
            set index {integer}
            set lang {string}
            set value {string}
        next
    next
end

config wireless-controller hotspot20 h2qp-osu-provider
    edit {name}
        config friendly-name
            edit {index}
                set index {integer}
                set lang {string}
                set friendly-name {string}
            next
        set server-uri {string}
        set osu-method {option}
        set osu-nai {string}
        config service-description
            edit {service-id}
                set service-id {integer}
                set lang {string}
                set service-description {string}
            next
        set icon {string}
    next
end

config wireless-controller hotspot20 h2qp-wan-metric
    edit {name}
        set link-status {option}
        set symmetric-wan-link {option}
        set link-at-capacity {enable | disable}
        set uplink-speed {integer}
        set downlink-speed {integer}
        set uplink-load {integer}
        set downlink-load {integer}
        set load-measurement-duration {integer}
    next
end

config wireless-controller hotspot20 hs-profile
    edit {name}
        set access-network-type {option}
        set access-network-internet {enable | disable}
        set access-network-asra {enable | disable}
        set access-network-esr {enable | disable}
        set access-network-uesa {enable | disable}
        set venue-group {option}
        set venue-type {option}
        set hessid {mac address}
        set proxy-arp {enable | disable}
        set l2tif {enable | disable}
        set pame-bi {enable | disable}
        set anqp-domain-id {integer}

```

```
    set domain-name {string}
    set osu-ssid {string}
    set gas-comeback-delay {integer}
    set gas-fragmentation-limit {integer}
    set dgaf {enable | disable}
    set deauth-request-timeout {integer}
    set wnm-sleep-mode {enable | disable}
    set bss-transition {enable | disable}
    set venue-name {string}
    set roaming-consortium {string}
    set nai-realm {string}
    set oper-friendly-name {string}
    config osu-provider
        edit {name}
        next
    set wan-metrics {string}
    set network-auth {string}
    set 3gpp-plmn {string}
    set conn-cap {string}
    set qos-map {string}
    set ip-addr-type {string}
next
end

config wireless-controller hotspot20 icon
    edit {name}
        config icon-list
            edit {name}
                set lang {string}
                set file {string}
                set type {option}
                set width {integer}
                set height {integer}
            next
        next
    next
end

config wireless-controller hotspot20 qos-map
    edit {name}
        config dscp-except
            edit {index}
                set index
                set dscp
                set up
            next
        config dscp-range
            edit {index}
                set index
                set up
                set low
                set high
            next
        next
    next
end
```

Allow admin with write permission to see plain text WiFi password (249787, 434513, 452834, 458211, 458285)

Add support for admins with write permission to read plain text password. Admins can view these plain text passwords (`captive-portal-radius-secret` and `passphrase`) under `config wireless-controller vap`. Note that `security` must be set as a WPA-personal setting.

WiFi Health Monitor page updates (392574, 392585, 404341, 417039, 434141, 440709)

The **WiFi Health Monitor** page list of active clients now shows their MAC address entries (similar to the **WiFi Client Monitor** page), making client information easier to view when opening the **Active Client** widget.

FortiAP LED Schedules (436227)

Support has been added for WTP profile LED schedules.

Use the command below (`led-schedule`) to assign recurring firewall schedules for illuminating LEDs on the FortiAP. This entry is only available when `led-state` is enabled, at which point LEDs will be visible when at least one of the schedules is valid.

Separate multiple schedule names with a space, as configured under `config firewall schedule group` and `config firewall schedule recurring`.

Syntax

```
config wireless-controller wtp-profile
  edit {name}
    set led-state {enable | disable}
    set led-schedules <name>
  next
end
```

Sharing Tunnel SSIDs within a single managed AP between VDOMs as a Virtual AP for multi-tenancy (439751)

Support has been added for the ability to move a tunnel mode VAP into a VDOM, similar to an interface/VLAN in VDOMs.

FortiAP is registered into the root VDOM. Within a customer VDOM, customer VAPs can be created/added. In the root VDOM, the customer VAP can be added to the registered FortiAP. Any necessary firewall rules and interfaces can be configured between the two VDOMs.

Syntax

```
config wireless-controller global
  set wtp-share {enable | disable}
end
```

30D/30E models support two normal-mode FAPs (446122)

Fixed an issue that blocked FortiGate 30D and 30E models from supporting two normal-mode FortiAPs.

MAC Bypass for Captive Portal (448296)

Support has been added to provide a MAC address bypass for authenticated clients. Previously, when clients were authenticated with bridged SSID and their MAC addresses were known, they were not redirected to the External Captive Portal.

A new portal type has been added, under `config wireless-controller vap`, to provide successful MAC authentication Captive Portal functionality.

Syntax

```
config wireless-controller vap
  edit {name}
    set portal-type {cmcc-macauth}
  next
end
```

WiFi Health Monitor fixes (449341)

An issue has been addressed where the **Client Count** widget (under **WiFi Health Monitor**) showed wrong options for the timeline selection.

The fixes include:

- Fixed timeline selection options to correct values.
- Updated time filter parameters with correct arguments in the **Login Failures** widget.
- Added local radio to **AP Status** widget details.
- Fixed **Login Failures** widget, where the SSID name was improperly formatted if it contained HTML characters.

Various bug fixes (452975, 455218, 453161, 405117, 453533, 453535, 184384)

Various fixes have been implemented to address a variety of issues:

The fixes include:

- Removed code to avoid repeated printing "parse dhcp options" after upgrade or reboot.
- Removed code that supported FAP-C221E, C226E, and C21D, as their product names changed.
- Changed the text for incorrect WiFi CLI help descriptions.
- Fixed background scan settings for FAP 222C, 223C, 321C, C220C, C225C, C23JD, and C24JE.
- Set WTP entry with "discovered" state to built-in in order to skip them, as only managed FAPs can be counted toward FAP capacity.

Configure how a FortiWiFi WiFi interface in client mode selects a WiFi band (455305)

For an FortiWiFi WiFi interface operating in client mode, you can use the following option to configure the WiFi band that the interface can connect to. You can configure the interface to connect to any band, just to the 5G band or to prefer connecting to the 5G band.

Syntax

```
config system interface
  edit {name}
    set wifi-ap-band {any | 5g-preferred | 5g-only}
  next
end
```

FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

Support for various FortiAP models (416177) (435638) (424483)

FortiAP units FAP-U321EV, FAP-U323EV, FAP-S221E, FAP-S223E, FAP-222E, FAP-221E, and FAP-223E are supported by FortiOS 5.6.1.

As part of this support, new CLI attributes have been added under `config wireless-controller wtp-profile` to manage their profiles.

CLI syntax

```
config wireless-controller wtp-profile
edit <model>
    config platform
        set type <model>
    end
    set ap-country <code>
    config radio-1
        set band 802.11n
    end
    config radio-2
        set band 802.11ac
    end
next
end
```

New Managed AP Groups and Dynamic VLAN Assignment (436267)

The FortiGate can create FortiAP Groups, under **WiFi & Switch Controller > Managed Devices > Managed FortiAPs** by selecting **Create New > Managed AP Group**, where multiple APs can be managed. AP grouping allows specific profile settings to be applied to many APs all at once that belong to a certain AP group, simplifying the administrative workload.

Note that each AP can only belong to one group.

In addition, VLANs can be assigned dynamically based on the group which an AP belongs. When defining an SSID, under **WiFi & Switch Controller > SSID**, a setting called **VLAN Pooling** can be enabled where you can either assign the VLAN ID of the AP group the device is connected to, to each device as it is detected, or to always assign the same VLAN ID to a specific device. Dynamic VLAN assignment allows the same SSID to be deployed to many APs, avoiding the need to produce multiple SSIDs.

GUI support for configuring multiple pre-shared keys for SSID interfaces (406321)

Multiple pre-shared keys can be created per SSID. When creating a new SSID, enable **Multiple Pre-shared Keys** under **WiFi Settings**.

FortiAP Bluetooth Low Energy (BLE) Scan (438274)

The FortiGate can configure FortiAP Bluetooth Low Energy (BLE) scan, incorporating Google's BLE beacon profile known as Eddystone, used to identify groups of devices and individual devices.

Currently, only the FAP-S221E, FAP-S223E, and FAP-222E models support this feature.

As part of this support, new CLI attributes have been added under `config wireless-controller timers` and `config wireless-controller wtp-profile`, including a new CLI command, `config wireless-controller ble-profile`.

CLI syntax - Configure BLE profiles

```
config wireless-controller ble-profile
  edit <name>
    set comment <comment>
    set advertising {ibeacon | eddystone-uid | eddystone-url}
    set ibeacon-uuid <uuid>
    set major-id <0 - 65535> - (default = 1000)
    set minor-id <0 - 65535> - (default = 1000)
    set eddystone-namespace <10-byte namespace>
    set eddystone-instance <device id>
    set eddystone-url <url>
    set txpower <0 - 12> - (default = 0)
    set beacon-interval <40 - 3500> - (default = 100)
    set ble-scanning {enable | disable} - (default = disable)
  next
end
```

Note that `txpower` determines the transmit power level on a scale of 0-12:

0: -21 dBm	1: -18 dBm	2: -15 dBm	3: -12 dBm	4: -9 dBm
5: -6 dBm	6: -3 dBm	7: 0 dBm	8: 1 dBm	9: 2 dBm
10: 3 dBm	11: 4 dBm	12: 5 dBm		

CLI syntax - Configure BLE report intervals

```
config wireless-controller timers
  set ble-scan-report-intv - (default = 30 sec)
end
```

CLI syntax - Assign BLE profiles to WTP profiles

```
config wireless-controller wtp-profile
  edit <name>
    set ble-profile <name>
  next
end
```

WiFi client monitor page search enhanced (440709)

WiFi Client Monitor page (**Monitor > WiFi Client Monitor**) now supports search function.

FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

Captive Portal Authentication with FortiAP in Bridge Mode (408915)

The FortiGate can operate as a web captive portal server to serve the captive portal local bridge mode.

A new CLI command has been added under `config wireless-controller vap` to set the captive portal type to CMCC, a wireless cipher.

CLI syntax

```
config wireless-controller vap
  edit <name>
    set portal-type { ... | cmcc }
  next
end
```

802.11kv(r) support (405498, 395037)

New CLI commands have been added under `config wireless-controller vap` to set various 802.11kv settings, or Voice Enterprise (802.11kv) and Fast Basic Service Set (BSS) Transition (802.11r), to provide faster and more intelligent roaming for the client.

CLI syntax

```
config wireless-controller vap
  edit <name>
    set voice-enterprise {enable | disable}
    set fast-bss-transition {enable | disable}
    set ft-mobility-domain
    set ft-r0-key-lifetime [1-65535]
    set ft-over-ds {enable | disable}
  next
end
```

External Captive Portal authentication with FortiAP in Bridge Mode (403115, 384872)

New CLI commands have been added under `config wireless-controller vap` to set various options for external captive portal with FortiAP in Bridge Mode. The commands set the standalone captive portal server category, the server's domain name or IP address, secret key to access the RADIUS server, and the standalone captive portal Access Controller (AC) name.

Note that these commands are only available when **local-standalone** is set to **enable** and **security** is set to **captive-portal**.

CLI syntax

```
config wireless-controller vap
  edit <name>
    set captive-portal-category {FortiCloud | CMCC} Default is FortiCloud.
    set captive-portal-radius-server <server>
    set captive-portal-radius-secret <password>
    set captive-portal-ac-name <name>
```

```
next
end
```

Japan DFS support for FAP-421E/423E/S421E/S423E (402287, 401434)

Korea and Japan Dynamic Frequency Selection (DFS) certification has been added for FAP-421E/423E/S421E/S423E. DFS is a mechanism that allows WLANs to select a frequency that does not interfere with certain radar systems while operating in the 5 GHz band.

802.3az support on WAVE2 WiFi APs (400558)

A new CLI command has been added under `config wireless-controller wtp-profile` to enable or disable use of Energy-Efficient Ethernet (EEE) on WTP, allowing for less power consumption during periods of low data activity.

CLI syntax

```
config wireless-controller wtp-profile
edit <profile-name>
set energy-efficient-ethernet {enable|disable}
end
```

CLI command update made in wids-profile (400263)

The CLI command `rogue-scan` under `config wireless-controller wids-profile` has been changed to `sensor-mode` and allows easier configuration of radio sensor mode. Note that while `foreign` enables radio sensor mode on foreign channels only, `both` enables the feature on foreign and home channels.

CLI syntax

```
config wireless-controller wids-profile
edit <example>
set sensor-mode {disable|foreign|both}
end
```

Channel utilization, FortiPresence support on AP mode, QoS enhancement for voice (399134, 377562)

A new CLI command has been added, `config wireless-controller qos-profile`, to configure quality of service (QoS) profiles where you can add WiFi multi-media (WMM) control and Differentiated Services Code Point (DSCP) mapping.

Note that:

- `call-capacity` and `bandwidth-admission-control` are only available when `call-admission-control` is set to `enable`.
- `bandwidth-capacity` is only available when `bandwidth-admission-control` is set to `enable`.
- All DSCP mapping options are only available when `dscp-wmm-mapping` is set to `enable`.
- `wmm` is already set to `enable` by default. If `wmm` is set to `disable`, the following entries are *not* available: `wmm-uapsd`, `call-admission-control`, and `dscp-wmm-mapping`.

CLI syntax

```
config wireless-controller qos-profile
edit <example>
```

```

set comment <comment>
set uplink [0-2097152] Default is 0 Kbps.
set downlink [0-2097152] Default is 0 Kbps.
set uplink-sta [0-2097152] Default is 0 Kbps.
set downlink-sta [0-2097152] Default is 0 Kbps.
set burst {enable|disable} Default is disable.
set wmm {enable|disable} Default is enable.
set wmm-uapsd {enable|disable} Default is enable.
set call-admission-control {enable|disable} Default is disable.
set call-capacity [0-60] Default is 10 phones.
set bandwidth-admission-control {enable|disable} Default is disable.
set bandwidth-capacity [1-600000] Default is 2000 Kbps.
set dscp-wmm-mapping {enable|disable} Default is disable.
set dscp-wmm-vo [0-63] Default is 48 56.
set dscp-wmm-vi [0-63] Default is 32 40.
set dscp-wmm-be [0-63] Default is 0 24.
set dscp-wmm-bk [0-63] Default is 8 16.

```

QoS profiles can be assigned under the `config wireless-controller vap` command using `qos-profile`.

FortiCloud managed APs can now be applied a bandwidth restriction or rate limitation based on SSID. For instance if guest and employee SSIDs are available, you can rate limit guest access to a certain rate to accommodate for employees. This feature also applies a rate limit based on the application in use, as APs are application aware.

FAP-U421E and FAP-U423E support (397900)

Two Universal FortiAP models support FortiOS 5.6. Their default profiles are added under `config wireless-controller wtp-profiles`, as shown below:

CLI syntax

```

config wireless-controller wtp-profile
  edit "FAPU421E-default"
    config platform
      set type U421E
    end
    set ap-country US
    config radio-1
      set band 802.11n
    end
    config radio-2
      set band 802.11ac
    end
  next
end

config wireless-controller wtp-profile
  edit "FAPU423E-default"
    config platform
      set type U423E
    end
    set ap-country US
    config radio-1
      set band 802.11n
    end
  end

```

```
config radio-2
  set band 802.11ac
end
next
end
```

Minor reorganization of WiFi GUI entries (396497)

WiFi & Switch Controller GUI entries **Managed FortiAPs**, **SSID**, **FortiAP Profiles**, and **WIDS Profiles** have been reorganized.

Multiple PSK support for WPA personal (393320, 264744)

New CLI commands have been added, under `config wireless-controller vap`, to configure multiple WiFi Protected Access Pre-Shared Keys (WPA-PSKs), as PSK is more secure without all devices having to share the same PSK.

Note that, for the following multiple PSK related commands to become available, `vdom`, `ssid`, and `passphrase` all have to be set first.

CLI syntax

```
config wireless-controller vap
  edit <example>
    set mpsk {enable|disable}
    set mpsk-concurrent-clients [0-65535] Default is 0.
    config mpsk-key
      edit key-name <example>
        set passphrase <wpa-psk>
        set concurrent-clients [0-65535] Default is empty.
        set comment <comments>
      next
    end
  end
end
```

Use the `mps-k-concurrent-clients` entry to set the maximum number of concurrent connected clients for each `mps-k` entry. Use the `mps-k-key` configuration method to configure multiple `mps-k` entries.

Table size of qos-profile has VDOM limit (388070)

The command `config wireless-controller qos-profile` now has VDOM table limit; there is no longer an unlimited number of entries within each VDOM.

Add "dhcp-lease-time" setting to local-standalone-nat VAP (384229)

When a Virtual Access Point (VAP) has been configured for a FortiAP, a DHCP server is automatically configured on the FortiAP side with a hard lease time. A new CLI command under `config wireless-controller vap` has been added to customize the DHCP lease time for NAT IP address. This is to solve issues where the DHCP IP pool was exhausted when the number of clients grew too large for the lease time span.

Note that the new command, `dhcp-lease-time`, is only available when `local-standalone` is set to `enable`, then setting `local-standalone-nat` to `enable`.

CLI syntax

```
config wireless-controller vap
  edit <example>
```

```

set local-standalone {enable|disable}
set local-standalone-nat {enable|disable}
set dhcp-lease-time [300-8640000] Default is 2400 seconds.
end

```

New CLI command to configure LDPC for FortiAP (383864)

Previously, LDPC value on FortiAP could only be changed on FortiAP local CLI. Syntax has been added in FortiOS CLI under the 'wireless-controller.vap' entry to configure the LDPC value on FortiAP.

CLI Syntax

```

configure wireless-controller vap
edit 1
set ldpc [enable|rx|tx|disable]
end

```

New region code/SKU for Indonesia (382926)

A new country region code, F, has been added to meet Indonesia's WiFi channel requirements. Indonesia previously belonged to region code W.

FortiAP RMA support added (381936)

New CLI command `fortiap` added under `exe replace-device` to replace an old FortiAP's serial number with a new one.

CLI Syntax

```
execute replace-device fortiap <old-fortiap-id> <new-fortiap-id>
```

Support fixed-length 64-hex digit for WPA-Personal passphrase (381030)

WPA-Personal passphrase now supports a fixed-length of 64 hexadecimal digits.

Allow FortiGates to manage cloud-based FortiAPs (380150)

FortiGates can now manage cloud-based FortiAPs using the new `fapc-compatibility` command under `wireless-controller setting`.

If enabled, default FAP-C wtp-profiles will be added. If disabled, FAP-C related CMDDB configurations will be removed: `wtp-group` in `vap's vlan-pool`, `wtp-group`, `ws`, `wtp`, `wtp-profile`.

CLI syntax

```

config wireless-controller setting
set country CN
set fapc-compatibility [enable|disable]
end

```

You will receive an error message when trying to change `country` while `fapc-compatibility` is enabled. You need to disable `fapc-compatibility` before changing to an FAPC unsupported country.

Use IPsec instead of DTLS to protect CAPWAP tunnels (379502)

This feature is to utilize FortiAP hardware to improve the throughput of tunneled data traffic by using IPsec when data security is enabled.

"AES-256-CBC & SHA256" algorithm and "dh_group 15" are used for both CAPWAP IPsec phase1 and phase 2.

FAP320B will not support this feature due to its limited capacity of free flash.

New option added to support only one IP per one endpoint association (378207)

When users change configuration, the radiusd will reset all configurations and refresh all logons in the kernel. All these actions are done in the one loop. A CLI option has been added to enable/disable replacement of an old IP address with a new IP address for the same endpoint on RADIUS accounting start.

CLI Syntax

```
configure user radius
  edit radius-root
    set rsso-ep-one-ip-only [enable|disable]
  next
end
```

FAP-222C-K DFS support (377795)

Dynamic Frequency Selection (DFS) bands can now be configured for FortiAP 222C-K.

Note that this FortiAP model has the Korean region code (K), but `ap-country` under `config wireless-controller wtp-profile` still needs to be set to KR.

CLI syntax

```
config wireless-controller wtp-profile
  edit <K-FAP222C>
    config platform
      set type <222C>
    end
    set ap-country KR
    config radio-2
      set band <802.11ac>
      set vap-all <disable>
      set vaps "vap-vd-07"
      set channel "52" "56" "60" "64" "100" "104" "108" "112" "116" "120" "124" "128"
        "132" "136" "140"
    end
  next
end
```

Dynamic VLAN support in standalone mode (377298)

Dynamic VLAN is now supported in standalone mode. Previously, dynamic VLAN only worked in local bridge mode.

CLI-only features added to GUI (376891)

Previously CLI-only features have been added to the GUI under **FortiAP Profiles**, **Managed FortiAPs**, and **SSID**. Also fixed issue where the correct value is displayed when viewing the **WIDS Profile** notification icon under **FortiAP Profiles**.

Managed AP GUI update (375376)

Upgraded Managed FortiAPs dialog page to a newer style, including icons for SSID and LAN port.

Bonjour gateway support (373659)

Bonjour gateway now supported for WiFi networks.

Syntax

```
config wireless-controller bonjour-profile
  edit 0
    set comment "comment"
    config policy-list
      edit 1
        set description "description"
        set from-vlan [0-4094] Default is 0.
        set to-vlan [0-4094|all] Default is all.
        set services [all|airplay|afp|bit-
          torrent|ftp|ichat|itunes|printers|samba|scanners|ssh|chromecast]
      next
    end
  next
end
```

FAP421E/423E wave2 support (371374)

Previously removed wave2 FAP421E and FAP423E models have been reinstated and are now supported again. The models are available again through the CLI and GUI. These models are listed under the **Platform** dropdown menu when creating a new FortiAP Profile under **WiFi & Switch Controller > FortiAP Profiles**.

CLI syntax

```
config wireless-controller wtp-profile
  edit <example>
    config platform
      set type <...|421E|423E>
    end
  end
end
```

WiFi Health Monitor GUI changes (308317)

The Wifi Health Monitor page has been improved, including the following changes:

- Flowchart used for diagrams
- Chart used for interference and AP clients
- Removed spectrum analysis
- Added functionality to upgrade FortiAP firmware
- Added option to view both 2.4GHz and 5GHz data simultaneously

AP Profile GUI page updates (298266)

The AP Profile GUI page has been upgraded to a new style including AngularJS code.

1+1 Wireless Controller HA (294656)

Instances of failover between FortiAP units was too long and lead to extended periods of time where WiFi users were without network connection. Because WiFi is considered a primary network connection in today's verticals (including enterprise, retail, education, warehousing, healthcare, government, and more), it is necessary for successful failover to occur as fast as possible.

You can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects the FortiGate. This process was previously decided on load-based detection, but can now be defined by each unit's pre-determined priority. In addition, heartbeat intervals have been lowered to further improve FortiAP awareness and successful failover.

Syntax

```
config wireless-controller inter-controller
  set inter-controller-mode {disable | l2-roaming | 1+1} Default is disable.
  set inter-controller-key <password>
  set inter-controller-pri {primary | secondary} Default is primary.
  set fast-failover-max [3-64] Default is 10.
  set fast-failover-wait [10-86400] Default is 10.
  config inter-controller-peer
    edit <name>
      set peer-ip <ip-address>
      set peer-port [1024-49150] Default is 5246.
      set peer-priority {primary | secondary} Default is primary.
    next
  end
end
```

Support for duplicate SSID names on tunnel and bridge mode interfaces (278955)

When `duplicate-ssid` is enabled in the CLI, this feature allows VAPs to use the same SSID name in the same VDOM. When disabled, all SSIDs in WLAN interface will be checked—if duplicate SSIDs exist, an error message will be displayed. When `duplicate-ssid` is enabled in the CLI, duplicate SSID check is removed in "Edit SSID" GUI page.

Syntax

```
config wireless-controller setting
  set duplicate-ssid [enable|disable]
next
end
```

Controlled failover between wireless controllers (249515)

Instances of failover between FortiAP units was too long and lead to extended periods of time where WiFi users were without network connection. Because WiFi is considered a primary network connection in today's verticals (including enterprise, retail, education, warehousing, healthcare, government, and more), it is necessary for successful failover to occur as fast as possible.

Administrators can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects the FortiGate. This process was decided on load-based detection, but can now be defined by each unit's pre-determined priority. In addition, heartbeat intervals have been lowered to further improve FortiAP awareness and successful failover.

Introduction to wireless networking

This chapter introduces some concepts you should understand before working with wireless networks, describes Fortinet's wireless equipment, and then describes the factors you need to consider in planning deployment of a wireless network.

Wireless concepts

Wireless networking is radio technology, subject to the same characteristics and limitations as the familiar audio and video radio communications. Various techniques are used to modulate the radio signal with a data stream.

Bands and channels

Depending on the wireless protocol selected, you have specific channels available to you, depending on what region of the world you are in.

- IEEE 802.11b and g protocols provide up to 14 channels in the 2.400-2.500 GHz Industrial, Scientific and Medical (ISM) band.
- IEEE 802.11a,n (5.150-5.250, 5.250-5.350, 5.725–5.875 GHz, up to 16 channels) in portions of Unlicensed National Information Infrastructure (U-NII) band

Note that the width of these channels exceeds the spacing between the channels. This means that there is some overlap, creating the possibility of interference from adjacent channels, although less severe than interference on the same channel. Truly non-overlapping operation requires the use of every fourth or fifth channel, for example ISM channels 1, 6 and 11.

The capabilities of your wireless clients is the deciding factor in your choice of wireless protocol. If your clients support it, 5GHz protocols have some advantages. The 5GHz band is less used than 2.4GHz and its shorter wavelengths have a shorter range and penetrate obstacles less. All of these factors mean less interference from other access points, including your own.

When configuring your WAP, be sure to correctly select the Geography setting to ensure that you have access only to the channels permitted for WiFi use in your part of the world.

For detailed information about the channel assignments for wireless networks for each supported wireless protocol, see [Reference on page 1555](#).

Power

Wireless LANs operate on frequencies that require no license but are limited by regulations to low power. As with other unlicensed radio operations, the regulations provide no protection against interference from other users who are in compliance with the regulations.

Power is often quoted in dBm. This is the power level in decibels compared to one milliwatt. 0dBm is one milliwatt, 10dBm is 10 milliwatts, 27dBm, the maximum power on Fortinet FortiAP equipment, is 500 milliwatts. The FortiGate unit limits the actual power available to the maximum permitted in your region as selected by the WiFi controller country setting.

Received signal strength is almost always quoted in dBm because the received power is very small. The numbers are negative because they are less than the one milliwatt reference. A received signal strength of -60dBm is one millionth of a milliwatt or one nanowatt.

Antennas

Transmitted signal strength is a function of transmitter power and antenna gain. Directional antennas concentrate the signal in one direction, providing a stronger signal in that direction than would an omnidirectional antenna.

FortiWiFi units have detachable antennas. However, these units receive regulatory approvals based on the supplied antenna. Changing the antenna might cause your unit to violate radio regulations.

Security

There are several security issues to consider when setting up a wireless network.

Whether to broadcast SSID

It is highly recommended to broadcast the SSID. This makes connection to a wireless network easier because most wireless client applications present the user with a list of network SSIDs currently being received. This is desirable for a public network.

Attempting to obscure the presence of a wireless network by not broadcasting the SSID does not improve network security. The network is still detectable with wireless network “sniffer” software. Clients search for SSIDs that they know, leaking the SSID. Refer to [RFC 3370](#). Also, many of the latest Broadcom drivers do not support hidden SSID for WPA2.

Encryption

Wireless networking supports the following security modes for protecting wireless communication, listed in order of increasing security.

None — Open system. Any wireless user can connect to the wireless network.

WEP64 — 64-bit Web Equivalent Privacy (WEP). This encryption requires a key containing 10 hexadecimal digits.

WEP128 — 128-bit WEP. This encryption requires a key containing 26 hexadecimal digits.

WPA — 256-bit WiFi Protected Access (WPA) security. This encryption can use either the TKIP or AES encryption algorithm and requires a key of either 64 hexadecimal digits or a text phrase of 8 to 63 characters. It is also possible to use a RADIUS server to store a separate key for each user.

WPA2 — WPA with security improvements fully meeting the requirements of the IEEE 802.11i standard. Configuration requirements are the same as for WPA.

For best security use the WPA2 with AES encryption and a RADIUS server to verify individual credentials for each user. WEP, while better than no security at all, is an older algorithm that is easily compromised. With either WEP or WAP, changing encryption passphrases on a regular basis further enhances security.

Separate access for employees and guests

Wireless access for guests or customers should be separate from wireless access for your employees. This does not require additional hardware. Both FortiWiFi units and FortiAP units support multiple wireless LANs on the

same access point. Each of the two networks can have its own SSID, security settings, firewall policies, and user authentication.

Two separate wireless networks are possible because multiple virtual APs can be associated with an AP profile. The same physical APs can provide two or more virtual WLANs.

Captive portal

As part of authenticating your users, you might want them to view a web page containing your acceptable use policy or other information. This is called a captive portal. No matter what URL the user initially requested, the portal page is returned. Only after authenticating and agreeing to usage terms can the user access other web resources.

For more information about captive portals, see the Captive portals chapter of the FortiOS Authentication Guide.

Power

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. There are people who look for wireless networks and attempt to access them. If your office WLAN is receivable out on the public street, you have created an opportunity for this sort of activity.

Monitoring for rogue APs

It is likely that there are APs available in your location that are not part of your network. Most of these APs belong to neighboring businesses or homes. They may cause some interference, but they are not a security threat. There is a risk that people in your organization could connect unsecured WiFi-equipped devices to your wired network, inadvertently providing access to unauthorized parties. The optional On-Wire Rogue AP Detection Technique compares MAC addresses in the traffic of suspected rogues with the MAC addresses on your network. If wireless traffic to non-Fortinet APs is also seen on the wired network, the AP is a rogue, not an unrelated AP.

Decisions about which APs are rogues are made manually on the Rogue AP monitor page. For detailed information, see [Wireless network monitoring on page 1489](#).

Suppressing rogue APs

When you have declared an AP to be a rogue, you have the option of suppressing it. To suppress an AP, the FortiGate WiFi controller sends reset packets to the rogue AP. Also, the MAC address of the rogue AP is blocked in the firewall policy. You select the suppression action on the Rogue AP monitor page. For more information, see [Wireless network monitoring on page 1489](#).

Rogue suppression is available only when there is a radio dedicated to scanning. It will not function during background scanning for spectrum analysis.

Wireless Intrusion Detection (WIDS)

You can create a WIDS profile to enable several types of intrusion detection:

- Unauthorized Device Detection
- Rogue/Interfering AP Detection
- Ad-hoc Network Detection and Containment

- Wireless Bridge Detection
- Misconfigured AP Detection
- Weak WEP Detection
- Multi Tenancy Protection
- MAC OUI Checking

For more information, see [Protecting the WiFi Network on page 1485](#).

Authentication

Wireless networks usually require authenticated access. FortiOS authentication methods apply to wireless networks the same as they do to wired networks because authentication is applied in the firewall policy.

The types of authentication that you might consider include:

- user accounts stored on the FortiGate unit
- user accounts managed and verified on an external RADIUS, LDAP or TACACS+ server
- Windows Active Directory authentication, in which users logged on to a Windows network are transparently authenticated to use the wireless network.

This Wireless chapter of the FortiOS Handbook will provide some information about each type of authentication, but more detailed information is available in the Authentication chapter.

What all of these types of authentication have in common is the use of user groups to specify who is authorized. For each wireless LAN, you will create a user group and add to it the users who can use the WLAN. In the identity-based firewall policies that you create for your wireless LAN, you will specify this user group.

Some access points, including FortiWiFi units, support MAC address filtering. You should not rely on this alone for authentication. MAC addresses can be “sniffed” from wireless traffic and used to impersonate legitimate clients.

Wireless networking equipment

Fortinet produces two types of wireless networking equipment:

- [FortiWiFi units](#), which are FortiGate units with a built-in wireless access point/client
- [FortiAP units](#), which are wireless access points that you can control from any FortiGate unit that supports the WiFi Controller feature.

FortiWiFi units

A FortiWiFi unit can:

- Provide an access point for clients with wireless network cards. This is called Access Point mode, which is the default mode.
or
- Connect the FortiWiFi unit to another wireless network. This is called Client mode. A FortiWiFi unit operating in client mode can only have one wireless interface.
or
- Monitor access points within radio range. This is called Monitoring mode. You can designate the detected access points as Accepted or Rogue for tracking purposes. No access point or client operation is possible in this mode. But,

you can enable monitoring as a background activity while the unit is in Access Point mode.

The Products section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiWiFi models that are currently available.

FortiAP units

FortiAP units are thin wireless access points are controlled by either a FortiGate unit or FortiCloud service.

FortiAP is a family of Indoor, Outdoor and Remote Access Point models supporting the latest single, dual, and triple stream MIMO 802.11ac and 802.11n technology, as well as 802.11g and 802.11a.

For large deployments, some FortiAP models support a mesh mode of operation in which control and data backhaul traffic between APs and the controller are carried on a dedicated WiFi network. Users can roam seamlessly from one AP to another.

In dual-radio models, each radio can function as an AP or as a dedicated monitor. The monitoring function is also available during AP operation, subject to traffic levels.

The Products section of the Fortinet web site (www.fortinet.com) provides detailed information about the FortiAP models that are currently available.

Automatic Radio Resource Provisioning

To prevent interference between APs, the FortiOS WiFi Controller includes the Distributed Automatic Radio Resource Provisioning (DARRP) feature. Through DARRP, each FortiAP unit autonomously and periodically determines the channel that is best suited for wireless communications. FortiAP units to select their channel so that they do not interfere with each other in large-scale deployments where multiple access points have overlapping radio ranges.

To enable ARRP - GUI

1. Go to **WiFi Controller > FortiAP Profiles** and edit the profile for your device.
2. In the Radio sections (Radio 1, Radio 2, etc.), enable **Radio Resource Provision**.
3. Click **OK**.

To enable ARRP - CLI

In this example, ARRP is enabled for both radios in the FAP321C-default profile:

```
config wireless-controller wtp-profile
  edit FAP321C-default
    config radio-1
      set darrp enable
    end
    config radio-2
      set darrp enable
    end
  end
end
```

Setting ARRP timing

By default, ARRP optimization occurs at a fixed interval of 1800 seconds (30 minutes). You can change this interval in the CLI. For example, to change the interval to 3600 seconds enter:

```
config wireless-controller timers
  set darrp-optimize 3600
end
```

Optionally, you can schedule optimization for fixed times. This enables you to confine ARRP activity to a low-traffic period. Setting `darrp-optimize` to 0, makes `darrp-day` and `darrp-time` available. For example, here's how to set DARRP optimization for 3:00am every day:

```
config wireless-controller timers
  set darrp-optimize 0
  set darrp-day sunday monday tuesday wednesday thursday friday saturday
  set darrp-time 03:00
end
```

Both `darrp-day` and `darrp-time` can accept multiple entries.

Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- [Introduction to Captive portals](#)
- [Configuring a captive portal](#)
- [Customizing captive portal pages](#)
- [Configuration example - Captive portal WiFi access control](#)

Introduction to Captive portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.
- **MAC Bypass** — when clients are authenticated against their bridged SSID and their MAC addresses are known, they are redirected to the external captive portal.

Configuring a captive portal

Captive portals are configured on network interfaces. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **System > Network > Interfaces**. On a physical (wired) network interface, you edit the interface configuration in **System > Network > Interfaces** and set **Security Mode** to **Captive Portal**.

To configure a WiFi Captive Portal - web-based manager:

1. Go to **WiFi Controller > WiFi Network > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **System > Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.

Security Mode: Captive Portal

Portal Type: ☒ Authentication ☐ Authentication + Disclaimer ☐ Disclaimer Only ☐ Email Collection

Authentication Portal: ☒ Local ☐ External

User Groups: Use Groups from Policies

Customize Portal Messages: Login Page

Redirect after Captive Portal: ☒ Original Request ☐ Specific URL

3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Introduction to Captive portals on page 1403 .
Authentication Portal	Local - portal hosted on the FortiGate unit. Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. See "Captive portals" on page 1405 .

4. Select **OK**.

To configure a wired Captive Portal - web-based manager:

1. Go to **System > Network > Interfaces** and edit the interface to which the users connect.
2. In **Security Mode** select **Captive Portal**.

Security Mode: Captive Portal

Authentication Portal: ☒ Local ☐ External

User Groups: Use Groups from Policies

Exempt List: Click to set...

Customize Portal Messages:

3. Enter

Authentication Portal	Local - portal hosted on the FortiGate unit.
	Remote - enter FQDN or IP address of external portal.
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy.
	Use Groups from Policies is not available in WiFi captive portals.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Enable, then select Edit. See Customizing captive portal pages on page 1405 .

4. Select **OK**.

Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
  edit r_exempt
    config rule
      edit 1
        set devices printer
      end
    end
  end
```

MAC Bypass for Captive Portal

It is possible to provide a MAC address bypass for authenticated clients. When clients are authenticated with bridged SSID and their MAC addresses are known, they are redirected to the External Captive Portal.

A new portal type has been added, under `config wireless-controller vap`, to provide successful MAC authentication Captive Portal functionality.

Syntax

```
config wireless-controller vap
  edit {name}
    set portal-type {cmcc-macauth}
  next
end
```

Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

The image shows a Fortinet captive portal login page. At the top, the Fortinet logo is displayed in black with a red square icon containing a white 'F'. Below the logo, the text 'Authentication Required' is centered in a bold, black font. Underneath this, a message 'Please enter your credentials to continue.' is centered. There are two input fields: 'Username:' followed by a white text box, and 'Password:' followed by a white text box. A 'Continue' button is located at the bottom right of the form area.

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line “Please enter your credentials to continue” is provided by the %%QUESTION%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line "Firewall authentication failed. Please try again." is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding. (WiFi or SSL VPN only)

Terms and Disclaimer Agreement

You are about to access Internet content that is not under the control of the network access provider. The network access provider is therefore not responsible for any of these sites, their content or their privacy policies. The network access provider and its staff do not endorse nor make any representations about these sites, or any information, software or other products or materials found there, or any results that may be obtained from using them. If you decide to access any Internet content, you do this entirely at your own risk and you are responsible for ensuring that any accessed material does not infringe the laws governing, but not exhaustively covering, copyright, trademarks, pornography, or any other material which is slanderous, defamatory or might cause offence in any other way.

Do you agree to the above terms?

Yes, I agree

No, I decline

- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file:

1. Go to **System > Config > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.
The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

To specify the new logo in the replacement message:

1. Go to **System > Network > Interfaces** and edit the interface.
The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.
By default it specifies the Fortinet logo: %%IMAGE:logo_fw_auth%%
4. Change the image name to the one you provided for your logo.
The tag should now read, for example, %%IMAGE:mylogo%%
5. Select **Save**.
6. Select **OK**.

Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

To modify portal page text

1. Go to **System > Network > Interfaces** and edit the interface.
The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
 - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
 - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may set `security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 172.16.101.1 255.255.255.0
    set allowaccess ping https ssh snmp http
    set type physical
    set explicit-web-proxy enable
    set alias "LAN"
    set security-mode captive-portal
    set snmp-index 1
  next
end
```

Roaming support

Client devices can maintain captive portal authentication as they roam across different APs. By maintaining a consistent authentication, uninterrupted access to latency sensitive applications such as VoIP is ensured.

The Cloud will push a random per-AP Network encryption key to the AP. The key is 32 bytes in length, and is used in captive portal fast roaming. All APs of an AP Network will use the same encryption key. This key is randomly generated, and will be updated daily.

Configuration example - Captive portal WiFi access control

In this scenario, you will configure the FortiGate for captive portal access so users can log on to your WiFi network.

You will create a user account (*rgreen*), add it to a user group (*employees*), create a captive portal SSID (*example-staff*), and configure a FortiAP unit. When the user attempts to browse the Internet, they will be redirected to the captive portal login page and asked to enter their username and password.

1. Enabling HTTPS authentication

Go to **User & Device > Authentication Settings**.

Under **Protocol Support**, enable **Redirect HTTP Challenge to a Secure Channel (HTTPS)**. This will make sure that user credentials are communicated securely through the captive portal.

2. Creating the user

Go to **User & Device > User Definition** and create a Local user (*rgreen*).

Create additional users if needed, and assign any authentication methods.

3. Creating the user group

Go to **User & Device > User Groups** and create a user group (*employees*).

Add **rgreen** to the group.

4. Creating the SSID

Go to **WiFi & Switch Controller > SSID** and configure the wireless network.
Some FortiGate models may show the GUI path as **WiFi & Switch Controller**.

Enter an **Interface Name** (*example-wifi*) and **IP/Network Mask**.

An address range under **DHCP Server** will be automatically configured.

Under **WiFi Settings**, enter an **SSID** name (*example-staff*), set **Security Mode** to **Captive Portal**, and add the **employees** user group.

5. Creating the security policy

Go to **Policy & Objects > Addresses** and create a new address for the SSID (*example-wifi-net*).

Set **Subnet/IP Range** to the same range set on the DHCP server in the previous step.

Set **Interface** to the SSID interface.

Go to **Policy & Objects > IPv4 Policy** and create a new policy for WiFi users to connect to the Internet.

Add both the **example-wifi-net** address and **employees** user group to **Source**.

6. Connecting and authorizing the FortiAP

Go to **Network > Interfaces** and edit an available interface.

Under **Address**, set **Addressing mode** to **Dedicated to Extension Device** and assign it an IP address.

Connect the FortiAP unit to the configured interface, then go to **WiFi & Switch Controller > Managed FortiAPs**.

The FortiAP is listed, but its **State** shows a greyed-out question mark — this is because it is waiting for authorization.

Highlight the FortiAP and select **Authorize**.

The question mark is now replaced by a red down-arrow — this is because it is authorized, but still offline.

Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile.

For each radio, enable **Radio Resource Provision** and select your SSID.

Go back to **WiFi & Switch Controller > Managed FortiAPs** to verify that the FortiAP unit is online.

7. Results

When a user attempts to connect to the wireless network, they will be redirected to the captive portal login screen.

Members of the **employees** group must enter their **Username** and **Password**. The user will then be redirected to the URL originally requested.

On the FortiGate, go to **Monitor > WiFi Client Monitor** to verify that the user is authenticated.

Configuring a WiFi LAN

When working with a FortiGate WiFi controller, you can configure your wireless network before you install any access points. If you are working with a standalone FortiWiFi unit, the access point hardware is already present but the configuration is quite similar. Both are covered in this section.

On FortiGate model 30D, web-based manager configuration of the WiFi controller is disabled by default. To enable it, enter the following CLI commands:

```
config system global
    set gui-wireless-controller enable
end
```

The WiFi Controller and Switch Controller are enabled through the Feature Store (under **System > Feature Select**). However, they are separately enabled and configured to display in the GUI via the CLI.

To enable both WiFi and Switch controllers, enter the following:

```
config system global
    set wireless-controller enable
    set switch-controller enable
end
```

To enable the GUI display for both controllers, have also been separated:

```
config system settings
    set gui-wireless-controller enable
    set gui-switch-controller enable
end
```

If you want to connect and authorize external APs, such as FortiAP units, see the next chapter, [Access point deployment](#).

Overview of WiFi controller configuration

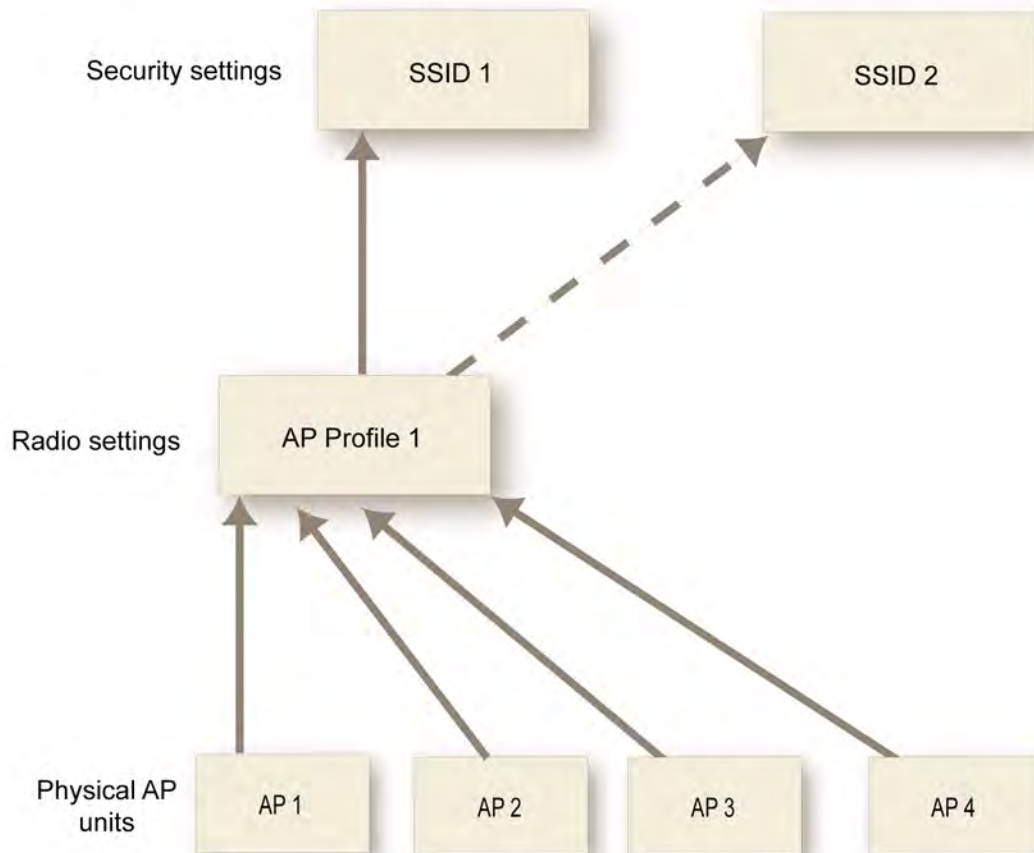

The FortiGate WiFi controller configuration is composed of three types of object, the SSID, the AP Profile and the physical Access Point.

- An **SSID** defines a virtual wireless network interface, including security settings. One SSID is sufficient for a wireless network, regardless how many physical access points are provided. You might, however, want to create multiple SSIDs to provide different services or privileges to different groups of users. Each SSID has separate firewall policies and authentication. Each radio in an access point can support up to 8 SSIDs.

A more common use of the term SSID is for the identifier that clients must use to connect to the wireless network. Each SSID (wireless interface) that you configure will have an SSID field for this identifier. In Managed Access Point configurations you choose wireless networks by SSID values. In firewall policies you choose wireless interfaces by their SSID name.

- An **AP Profile** defines the radio settings, such as band (802.11g for example) and channel selection. The AP Profile names the SSIDs to which it applies. Managed APs can use automatic profile settings or you can create AP profiles.
- **Managed Access Points** represent local wireless APs on FortiWiFi units and FortiAP units that the FortiGate unit has discovered. There is one managed access point definition for each AP device. An access point definition can use automatic AP profile settings or select a FortiAP Profile. When automatic profile settings are used, the managed AP definition also selects the SSIDs to be carried on the AP.

Conceptual view of FortiGate WiFi controller configuration

About SSIDs on FortiWiFi units

FortiWiFi units have a default SSID (wireless interface) named **wlan**. You can modify or delete this SSID as needed. As with external APs, the built-in wireless AP can be configured to carry any SSID.

The AP settings for the built-in wireless access point are located at **WiFi Controller > Local WiFi Radio**. The available operational settings are the same as those for external access points which are configured at **WiFi Controller > Managed FortiAPs**.

Process to create a wireless network

To set up your wireless network, you will need to perform the following steps:

- Make sure the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.
- Optionally, if you don't want to use automatic AP profile settings, configure a FortiAP profile, specifying the radio settings and the SSIDs to which they apply.
- Configure one or more SSIDs for your wireless network. The SSID configuration includes DHCP and DNS settings.
- Configure the user group and users for authentication on the WLAN.
- Configure the firewall policy for the WLAN.
- Optionally, customize the captive portal.
- Configure access points.
Configuration of the built-in AP on FortiWiFi units is described in this chapter. Connection and configuration of FortiAP units is described in the next chapter, see [Access point deployment on page 1437](#).

Setting your geographic location

The maximum allowed transmitter power and permitted radio channels for WiFi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

To change the location setting - CLI

To change the country to France, for example, enter

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') instead of a country code.

Before changing the country setting, you must remove all FortiAP Profiles. To do this, go to **WiFi & Switch Controller > FortiAP Profiles**.

View all Country & Regcodes/Regulatory Domains

The following CLI command can be entered to view a list of the Country & Regcodes/Regulatory Domains supported by Fortinet:

```
cw_diag -c all-countries
```

Below is a table showing a sample of the list displayed by entering this command:

Country-code	Region-code	Domain	ISO-name	Name
0	A	FCC3 & FCCA	NA	NO_COUNTRY_SET
8	W	NULL1 & WORLD	AL	ALBANIA
12	W	NULL1 & WORLD	DZ	ALGERIA
16	A	FCC3 & FCCA	AS	AMERICAN SAMOA
...

Creating a FortiAP Profile

A FortiAP Profile defines radio settings for a particular platform (FortiAP model). The profile also selects which SSIDs (virtual APs) the APs will carry. FortiAP units contain two radio transceivers, making it possible, for example, to provide both 2.4GHz 802.11b/g/n and 5GHz 802.11a/n service from the same access point. The radios can also be used for monitoring, used for the Rogue AP detection feature.

You can modify existing FortiAP profiles or create new ones of your own.

On FortiGate model 30D, web-based manager configuration of FortiAP Profiles is disabled by default. To enable AP profiles, enter the following CLI commands:

```
config system settings
  set gui-ap-profile enable
end
```

To configure a FortiAP Profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and select **Create New**.
2. Enter a **Name** for the FortiAP Profile.
3. In **Platform**, select the FortiWiFi or FortiAP model to which this profile applies.
4. If split tunneling is used, in **Split Tunneling Subnets**, enter a comma-separated list all of the destination IP address ranges that should **not** be routed through the the FortiGate WiFi controller.
5. For each radio, enter:

Mode	Select the type of mode. Disable – radio disabled Access Point – the platform is an access point Dedicated Monitor – the platform is a dedicated monitor. See Wireless network monitoring on page 1489 .
WIDS Profile	Optionally, select a Wireless Intrusion Detection (WIDS) profile. See Protecting the WiFi Network on page 1485 .
Radio Resource Provision	Select to enable the radio resource provision feature. This feature measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.
Client Load Balancing	Select Frequency Handoff or AP Handoff as needed. See Access point deployment on page 1437 .
Band	Select the wireless protocols that you want to support. The available choices depend on the radio's capabilities. Where multiple protocols are supported, the letter suffixes are combined: "802.11g/b" means 802.11g and 802.11b. Note that on two-radio units such as the FortiAP-221C it is not possible to put both radios on the same band.

Channel Width	Select channel width for 802.11ac or 802.11n on 5GHz.
Short Guard Interval	Select to enable the short guard interval for 802.11ac or 802.11n on 5GHz.
Channels	Select the channel or channels to include. The available channels depend on which IEEE wireless protocol you selected in Band . By default, all available channels are enabled.
TX Power Control	Enable automatic or manual adjustment of transmit power, specifying either minimum and maximum power levels in dBm or as a percentage.
TX Power	<p>When TX Power Control is set to Auto, the TX Power is set by default to a range of 10-17 dBm. Set the range between 1-20 for both the lower and upper limits.</p> <p>When TX Power Control is set to Manual, the TX Power is set by default to 100% of the maximum power permitted in your region. To change the level, drag the slider.</p>
SSIDs	<p>Select between Auto or Manual. Selecting Auto eliminates the need to re-edit the profile when new SSIDs are created. However, you can still select SSIDs individually using Manual.</p> <p>Note that automatic assignment of SSIDs (Auto) is not available for FortiAPs in Local Bridge mode. The option is hidden on both the Managed FortiAP settings and the FortiAP Profile assigned to that AP.</p>

Radio 1 settings are the same as Radio 2 settings except for the options for **Channel**.

Radio 2 settings are available only for FortiAP models with dual radios.

6. Select **OK**.

To configure a FortiAP Profile - CLI

This example configures a FortiAP-220B to carry all SSIDs on Radio 1 but only SSID example_wlan on Radio 2.

```
config wireless-controller wtp-profile
  edit guest_prof
    config platform
      set type 220B
    end
    config radio-1
      set mode ap
      set band 802.11g
      set vap-all enable
    end
    config radio-2
      set mode ap
      set band 802.11g
      set vaps example_wlan
    end
  end
end
```

Defining a wireless network interface (SSID)

You begin configuring your wireless network by defining one or more SSIDs to which your users will connect. When you create an SSID, a virtual network interface is also created with the **Name** you specified in the SSID configuration. You can configure the settings of an existing SSID in either **WiFi Controller > WiFi Network > SSID** or **System > Network > Interface**.

If a software switch interface contains an SSID (but only one), the WiFi SSID settings are available in the switch interface settings.

To create a new SSID

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Fill in the SSID fields as described below.

To configure the settings of an existing SSID

1. Either
 - Go to **WiFi & Switch Controller > SSID**.
 or
 - Go to **Network > Interfaces**.
WiFi interfaces list the SSID beside the interface **Name**.
2. Edit a WiFi interface, modifying the SSID fields as needed.

SSID fields

Interface Name	Enter a name for the SSID interface.
Type	WiFi SSID.
Traffic Mode	<p>Tunnel to Wireless Controller — Data for WLAN passes through WiFi Controller. This is the default.</p> <p>Local bridge with FortiAP's Interface — FortiAP unit Ethernet and WiFi interfaces are bridged.</p> <p>Mesh Downlink — Radio receives data for WLAN from mesh backhaul SSID.</p>
IP/Network Mask	Enter the IP address and netmask for the SSID.
IPv6 Address	Enter the IPv6 address. This is available only when IPv6 has been enabled on the unit.
Administrative Access	Select which types of administrative access are permitted on this SSID.

IPv6 Administrative Access	If you have IPv6 addresses, select the permitted IPv6 administrative access types for this SSID.
DHCP Server	<p>To assign IP addresses to clients, enable DHCP server. You can define IP address ranges for a DHCP server on the FortiGate unit or relay DHCP requests to an external server.</p> <p>If the unit is in transparent mode, the DHCP server settings will be unavailable.</p> <p>For more information, see Configuring DHCP for WiFi clients on page 1422.</p>
Device Detection	Detect connected device type. Enabled by default.
Active Scanning	Enabled by default.
WiFi Settings	
SSID	Enter the SSID. By default, this field contains <code>fortinet</code> .
Security Mode	<p>Select the security mode for the wireless interface. Wireless users must use the same security mode to be able to connect to this wireless interface. Additional security mode options are available in the CLI. For more information, see Configuring security on page 1423.</p> <p>Captive Portal – authenticates users through a customizable web page.</p> <p>WPA2-Personal – WPA2 is WiFi Protected Access version 2. There is one pre-shared key (password) that all users use.</p> <p>WPA2-Personal with Captive Portal – The user will need to know the pre-shared key and will also be authenticated through the custom portal.</p> <p>WPA2-Enterprise – similar to WPA2-Personal, but is best used for enterprise networks. Each user is separately authenticated by user name and password.</p>
Pre-shared Key	Available only when Security Mode is WPA2-Personal . Enter the encryption key that the clients must use.
Authentication	<p>Available only when Security Mode is WPA2-Enterprise.</p> <p>Select one of the following:</p> <p>RADIUS Server — Select the RADIUS server that will authenticate the clients.</p> <p>Local – Select the user group(s) that can authenticate.</p>
Portal Type	Available only when Security Mode is Captive Portal . Choose the captive portal type. Authentication is available with or without a usage policy disclaimer notice.

Authentication Portal	Local - portal hosted on the FortiGate unit External - enter FQDN or IP address of external portal
User Groups	Select permitted user groups for captive portal authentication.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the listed portal pages to edit them.
Redirect after Captive Portal	Optionally, select Specific URL and enter a URL for user redirection after captive portal authentication. By default, users are redirected to the URL that they originally requested.
Allow New WiFi Client Connections When Controller Is Down	This option is available for local bridge SSIDs with WPA-Personal security. See Combining WiFi and wired networks with a software switch on page 1470 .
Broadcast SSID	Optionally, disable broadcast of SSID. By default, the SSID is broadcast. For more information, see Introduction to wireless networking on page 1397 .
Schedule	Select when the SSID is enabled. You can choose any schedule defined in Policy & Objects > Objects > Schedules .
Block Intra-SSID Traffic	Select to enable the unit to block intra-SSID traffic.
Maximum Clients	Select to limit the number of clients permitted to connect simultaneously. Enter the limit value.
Split Tunneling	Select to enable some subnets to remain local to the remote FortiAP. Traffic for these networks is not routed through the WiFi Controller. Specify split-tunnel networks in the FortAP Profile. See Split tunneling on page 1476 .
Optional VLAN ID	Enter the ID of the VLAN this SSID belongs to. Enter 0 for non-VLAN operation.
Enable Explicit Web Proxy	Select to enable explicit web proxy for the SSID.
Listen for RADIUS Accounting Messages	Enable if you are using RADIUS-based Single Sign-On (SSO).
Secondary IP Address	Optionally, enable and define secondary IP addresses. Administrative access can be enabled on secondary interfaces.

Comments	Enter a description or comment for the SSID.
-----------------	--

To configure a virtual access point (SSID) - CLI

The example below creates an access point with SSID “example” and WPA2-Personal security. The wireless interface is named example_wlan.

WiFi SSIDs include a schedule that determines when the WiFi network is available. The default schedule is Always. You can choose any schedule (but not schedule group) that is defined in **Policy & Objects > Objects > Schedules**.

```
config wireless-controller vap
  edit example_wlan
    set ssid "example"
    set broadcast-ssid enable
    set security wpa2-only-personal
    set passphrase "hardtoguess"
    set schedule always
    set vdom root
  end
config system interface
  edit example_wlan
    set ip 10.10.120.1 255.255.255.0
  end
```

Configuring DHCP for WiFi clients

Wireless clients need to have IP addresses. If you use RADIUS authentication, each user’s IP address can be stored in the Framed-IP-Address attribute. Otherwise, you need to configure a DHCP server on the WLAN interface to assign IP addresses to wireless clients.

To configure a DHCP server for WiFi clients - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **DHCP Server** select **Enable**.
3. In **Address Range**, select **Create New**.
4. In the **Starting IP** and **End IP** fields, enter the IP address range to assign.
By default an address range is created in the same subnet as the wireless interface IP address, but not including that address.
5. Set the **Netmask** to an appropriate value, such as 255.255.255.0.
6. Set the **Default Gateway** to **Same as Interface IP**.
7. Set the **DNS Server** to **Same as System DNS**.
8. If you want to restrict access to the wireless network by MAC address, see [Adding a MAC filter on page 1425](#).
9. Select **OK**.

To configure a DHCP server for WiFi clients - CLI

In this example, WiFi clients on the example_wlan interface are assigned addresses in the 10.10.120.2-9 range to connect with the WiFi access point on 10.10.120.1.

```
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
```

```
set dns-service default
set interface example_wlan
set netmask 255.255.255.0
config ip-range
  edit 1
    set end-ip 10.10.120.9
    set start-ip 10.10.120.2
  end
end
```

You cannot delete an SSID (wireless interface) that has DHCP enabled on it.

Configuring security

Using the web-based manager, you can configure Captive Portal security or WiFi Protected Access version 2 (WPA2) security modes WPA2-Personal and WPA2-Enterprise. Using the CLI, you can also choose WPA/WPA2 modes that support both WPA version 1 and WPA version 2.

WPA2 security with a pre-shared key for authentication is called WPA2-Personal. This can work well for one person or a small group of trusted people. But, as the number of users increases, it is difficult to distribute new keys securely and there is increased risk that the key could fall into the wrong hands.

A more secure form of WPA2 security is WPA2-Enterprise. Users each have their own authentication credentials, verified through an authentication server, usually RADIUS. FortiOS can also authenticate WPA2-Enterprise users through its built-in user group functionality. FortiGate user groups can include RADIUS servers and can select users by RADIUS user group. This makes possible Role-Based Access Control (RBAC).

By default, WPA2 security encrypts communication using Advanced Encryption Standard (AES). But some older wireless clients support only Temporal Key Integrity Protocol (TKIP). You can change the encryption to TKIP or negotiable TKIP-AES in the CLI. For example, to accommodate clients with either TKIP or AES, enter:

```
config wireless-controller vap
  edit example_wlan
    set security wpa-personal
    set passphrase "hardtoguess"
    set encrypt TKIP-AES
  end
```

Captive Portal security connects users to an open web portal defined in replacement messages. To navigate to any location beyond the web portal, the user must pass FortiGate user authentication.

WPA-Personal security

WPA2-Personal security setup requires only the preshared key that you will provide to your clients.

To configure WPA2-Personal security - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Personal**.
3. In **Pre-shared Key**, enter a key between 8 and 63 characters long.
4. Select **OK**.

To configure WPA2-Personal security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa2-personal
    set passphrase "hardtoguess"
  end
```

WPA-Enterprise security

If you will use FortiOS user groups for authentication, go to **User & Device > User > User Groups** and create those groups first. The groups should be Firewall groups.

If you will use a RADIUS server to authenticate wireless clients, you must first configure the FortiGate unit to access the RADIUS server.

To configure FortiGate unit access to the RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

RADIUS Change of Authorization (CoA) support

The CoA feature enables the FortiGate to receive a client disconnect message from the RADIUS server. This is used to disconnect clients when their time, credit or bandwidth had been used up. Enable this on the RADIUS server using the CLI:

```
config user radius
  edit <name>
    set radius-coa enable
  end
```

To configure WPA-Enterprise security - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In **Security Mode**, select **WPA2 Enterprise**.
3. In **Authentication**, do one of the following:
 - If you will use a RADIUS server for authentication, select **RADIUS** Server and then select the RADIUS server.
 - If you will use a local user group for authentication, select **Local** and then select the user group(s) permitted to use the wireless network.

4. Select **OK**.

To configure WPA-Enterprise security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa2-enterprise
    set auth radius
    set radius-server exampleRADIUS
  end
```

Captive Portal security

Captive Portal security provides an access point that initially appears open. The wireless client can connect to the AP with no security credentials. The AP responds to the client's first HTTP request with a web page requesting user name and password. Until the user enters valid credentials, no communication beyond the AP is permitted.

The captive portal can be hosted on the FortiGate unit, or externally. For details see

[Configuring WiFi captive portal security - FortiGate captive portal on page 1427](#)

[Configuring WiFi captive portal security - external server on page 1427](#)

For general information about captive portals, see the Captive Portal chapter of the Authentication Guide.

Adding a MAC filter

On each SSID, you can create a MAC address filter list to either permit or exclude a list of clients identified by their MAC addresses.

This is actually not as secure as it appears. Someone seeking unauthorized access to your network can obtain MAC addresses from wireless traffic and use them to impersonate legitimate users. A MAC filter list should only be used in conjunction with other security measures such as encryption.

To configure a MAC filter - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID entry.
2. In the **DHCP Server** section, expand **Advanced**.
3. In **MAC Reservation + Access Control**, double-click in the **Unknown MAC Addresses** line and select **Assign IP** or **Block**, as needed.
By default, unlisted MAC addresses are assigned an IP address automatically.
4. In **MAC Reservation + Access Control**, select **Create New**.
5. Enter a MAC address in the **MAC** field.
6. In **IP or Action**, select one of:
 - **Reserve IP** — enter the IP address that is always assigned to this MAC address.
 - **Assign IP** — an IP address is assigned to this MAC address automatically.
 - **Block** — This MAC address will not be assigned an IP address.
7. Repeat steps 4 through 6 for each additional MAC address that you want to add.
8. Select **OK**.

To configure a MAC filter - CLI

1. Enter

```
config system dhcp server
show
```

2. Find the entry where `interface` is your WiFi interface. Edit that entry and configure the MAC filter. In this example, the MAC address 11:11:11:11:11:11 will be excluded. Unlisted MAC addresses will be assigned an IP address automatically.

```
edit 3
config reserved-address
edit 1
set action block
set mac 11:11:11:11:11:11
end
set mac-acl-default-action assign
end
```

Limiting the number of clients

You might want to prevent overloading of your access point by limiting the number of clients who can associate with it at the same time. Limits can be applied per SSID, per AP, or per radio.

To limit the number of clients per SSID - GUI

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID.
2. Turn on **Maximum Clients** and enter the maximum number of clients in **Limit Concurrent WiFi Clients**.

To limit the number of clients per AP- CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
edit "FAP221C-default"
set max-clients 30
end
```

To limit the number of clients per radio - CLI

Edit the wtp-profile (FortiAP profile), like this:

```
config wireless-controller wtp-profile
edit "FAP221C-default"
config radio-1
set max-clients 10
end
config radio-2
set max-clients 30
end
end
```

Multicast enhancement

FortiOS can translate multicast traffic into unicast traffic to send to clients, maintaining its own multicast client through IGMP snooping. You can configure this in the CLI:

```
config wireless-controller vap
edit example_wlan
set multicast-enhance enable
set me-disable-thresh 32
```

```
end
```

If the number of clients on the SSID is larger than `me-disable-thresh`, multicast enhancement is disabled.

Configuring WiFi captive portal security - FortiGate captive portal

The built-in FortiGate captive portal is simpler than an external portal. It can even be customized if needed.

To configure a WiFi Captive Portal - web-based manager:

1. Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.
3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection. See Defining a wireless network interface (SSID) on page 1419 .
Authentication Portal	Local
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Customize Portal Messages	Click the link of the portal page that you want to modify. For more information see the Captive Portal chapter of the Authentication Guide.

4. Select **OK**.

Configuring WiFi captive portal security - external server

An external captive portal is a web page on a web server. The essential part of the web portal page is a script that gathers the user's logon credentials and sends back to the FortiGate a specifically-formatted POST message. The portal page can also contain links to local information such as legal notices, terms of service and so on. Without authenticating, the user cannot access any other information. This is sometimes called a "walled garden".

On the captive portal page, the user submits credentials, which the script returns to the FortiGate at the URL `https://<FGT_IP>:1000/fgtauth` with data `magic=session_id&username=<username>&password=<password>`.
(The magic value was provided in the initial FortiGate request to the web server.)

To ensure that credentials are communicated securely, enable the use of HTTPS for authentication:

```
config user setting
  set auth-secure-http enable
end
```

To configure use of an external WiFi Captive Portal - web-based manager:

1. Go to **WiFi & Switch Controller > SSID** and create your SSID.
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
2. In **Security Mode**, select **Captive Portal**.
3. Enter

Portal Type	The portal can provide authentication and/or disclaimer, or perform user email address collection.
Authentication Portal	External - enter the FQDN or IP address of the external portal. Typically, this is the URL of a script. Do not include the protocol (http:// or https://) part of the URL.
User Groups	Select permitted user groups or select Use Groups from Policies , which permits the groups specified in the security policy.
Exempt List	Select exempt lists whose members will not be subject to captive portal authentication.
Redirect after Captive Portal	Original Request Specific URL - enter URL

4. Select **OK**.

Defining SSID Groups

Optionally, you can define SSID Groups. An SSID Group has SSIDs as members and can be specified just like an SSID in a FortiAP Profile.

To create an SSID Group - GUI

Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID Group**. Give the group a **Name** and choose **Members** (SSIDs, but not SSID Groups).

To create an SSID Group - CLI:

```
config wireless-controller vap-group
  edit vap-group-name
    set vaps "ssid1" "ssid2"
  end
```

Dynamic user VLAN assignment

Clients connecting to the WiFi network can be assigned to a VLAN. You can do this with RADIUS attributes when the user authenticates or with VLAN pooling when the client associates with a particular FortiAP. You cannot use both of these methods at the same time.

VLAN assignment by RADIUS

You can assign each individual user to a VLAN based on information stored in the RADIUS authentication server. If the user's RADIUS record does not specify a VLAN ID, the user is assigned to the default VLAN for the SSID.

The RADIUS user attributes used for the VLAN ID assignment are:

IETF 64 (Tunnel Type)—Set this to VLAN.

IETF 65 (Tunnel Medium Type)—Set this to 802

IETF 81 (Tunnel Private Group ID)—Set this to the VLAN ID.

To configure dynamic VLAN assignment, you need to:

1. Configure access to the RADIUS server.
2. Create the SSID and enable dynamic VLAN assignment.
3. Create a FortiAP Profile and add the local bridge mode SSID to it.
4. Create the VLAN interfaces and their DHCP servers.
5. Create security policies to allow communication from the VLAN interfaces to the Internet.
6. Authorize the FortiAP unit and assign the FortiAP Profile to it.

To configure access to the RADIUS server

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name**, the name or IP address in **Primary Server IP/Name**, and the server secret in **Primary Server Secret**.
3. Select **OK**.

To create the dynamic VLAN SSID

1. Go to **WiFi & Switch Controller > SSID**, select **Create New > SSID** and enter:

Name	An identifier, such as dynamic_vlan_ssid.
Traffic Mode	Local bridge or Tunnel, as needed.
SSID	An identifier, such as DYNSSID.
Security Mode	WPA2 Enterprise
Authentication	RADIUS Server. Select the RADIUS server that you configured.

2. Select **OK**.
3. Enable dynamic VLAN in the CLI. Optionally, you can also assign a VLAN ID to set the default VLAN for users without a VLAN assignment.

```
config wireless-controller vap
  edit dynamic_vlan_ssid
    set dynamic-vlan enable
    set vlanid 10
  end
```

To create the FortiAP profile for the dynamic VLAN SSID

1. Go to **WiFi & Switch Controller > FortiAP Profiles**, select **Create New** and enter:

Name	A name for the profile, such as dyn_vlan_profile.
Platform	The FortiAP model you are using. If you use more than one model of FortiAP, you will need a FortiAP Profile for each model.
Radio 1 and Radio 2	
SSID	Select the SSID you created (example dynamic_vlan_ssid). Do not add other SSIDs.

2. Adjust other radio settings as needed.
3. Select **OK**.

To create the VLAN interfaces

1. Go to **Network > Interfaces** and select **Create New > Interface**.
2. Enter:

Name	A name for the VLAN interface, such as VLAN100.
Interface	The physical interface associated with the VLAN interface.
VLAN ID	The numeric VLAN ID, for example 100.
Addressing mode	Select Manual and enter the IP address / Network Mask for the virtual interface.
DHCP Server	Enable and then select Create New to create an address range.

3. Select **OK**.
4. Repeat the preceding steps to create other VLANs as needed.

Security policies determine which VLANs can communicate with which other interfaces. These are the simple Firewall Address policy without authentication. Users are assigned to the appropriate VLAN when they authenticate.

To connect and authorize the FortiAP unit

1. Connect the FortiAP unit to the FortiGate unit.
2. Go to **WiFi & Switch Controller > Managed FortiAPs**.
3. When the FortiAP unit is listed, double-click the entry to edit it.
4. In **FortiAP Profile**, select the FortiAP Profile that you created.
5. Select **Authorize**.
6. Select **OK**.

VLAN assignment by VLAN pool

In an SSID, you can define a VLAN pool. As clients associate to an AP, they are assigned to a VLAN. A VLAN pool can

- assign a specific VLAN based on the AP's FortiAP Group, usually for network configuration reasons, or
- assign one of several available VLANs for network load balancing purposes (tunnel mode SSIDs only)

To assign a VLAN by FortiAP Group - CLI

In this example, VLAN 101, 102, or 103 is assigned depending on the AP's FortiAP Group.

```
config wireless-controller vap
  edit wlan
    set vlan-pooling wtp-group
    config vlan-pool
      edit 101
        set wtp-group wtpgrp1
      next
      edit 102
        set wtp-group wtpgrp2
      next
      edit 103
        set wtp-group wtpgrp3
      end
    end
  end
```

Load balancing

There are two VLAN pooling methods used for load balancing:

The choice of VLAN can be based on any one of the following criteria:

- **round-robin** - from the VLAN pool, choose the VLAN with the smallest number of clients
- **hash** - choose a VLAN from the VLAN pool based on a hash of the current number of SSID clients and the number of entries in the VLAN pool

If the VLAN pool contains no valid VLAN ID, the SSID's static VLAN ID setting is used.

To assign a VLAN by round-robin selection - CLI

In this example, VLAN 101, 102, or 103 is assigned using the round-robin method:

```
config wireless-controller vap
  edit wlan
    set vlan-pooling round-robin
    config vlan-pool
      edit 101
      next
      edit 102
      next
      edit 103
      end
    end
  end
```

To assign a VLAN by hash-based selection - CLI

In this example, VLAN 101, 102, or 103 is assigned using the hash method:

```
config wireless-controller vap
  edit wlan
    set vlan-pooling hash
    config vlan-pool
      edit 101
      next
      edit 102
      next
      edit 103
      end
    end
  end
end
```

Configuring user authentication

You can perform user authentication when the wireless client joins the wireless network and when the wireless user communicates with another network through a firewall policy. WEP and WPA-Personal security rely on legitimate users knowing the correct key or passphrase for the wireless network. The more users you have, the more likely it is that the key or passphrase will become known to unauthorized people. WPA-Enterprise and captive portal security provide separate credentials for each user. User accounts can be managed through FortiGate user groups or an external RADIUS authentication server.

WPA2 Enterprise authentication

Enterprise authentication can be based on the local FortiGate user database or on a remote RADIUS server. Local authentication is essentially the same for WiFi users as it is for wired users, except that authentication for WiFi users occurs when they associate their device with the AP. Therefore, enterprise authentication must be configured in the SSID. WiFi users can belong to user groups just the same as wired users and security policies will determine which network services they can access.

If your WiFi network uses WPA2 Enterprise authentication verified by a RADIUS server, you need to configure the FortiGate unit to connect to that RADIUS server.

Configuring connection to a RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter a **Name** for the server.
This name is used in FortiGate configurations. It is not the actual name of the server.
3. In **Primary Server Name/IP**, enter the network name or IP address for the server.
4. In **Primary Server Secret**, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select **OK**.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
```

end

To implement WPA2 Enterprise security, you select this server in the SSID security settings. See [Configuring user authentication on page 1432](#).

To use the RADIUS server for authentication, you can create individual FortiGate user accounts that specify the authentication server instead of a password, and you then add those accounts to a user group. Or, you can add the authentication server to a FortiGate user group, making all accounts on that server members of the user group.

Creating a wireless user group

Most wireless networks require authenticated access. To enable creation of firewall policies specific to WiFi users, you should create at least one WiFi user group. You can add or remove users later. There are two types of user group to consider:

- A Firewall user group can contain user accounts stored on the FortiGate unit or external authentication servers such as RADIUS that contain and verify user credentials.
- A Fortinet Single Sign-On (FSSO) user group is used for integration with Windows Active Directory or Novell eDirectory. The group can contain Windows or Novell user groups who will be permitted access to the wireless LAN.

WiFi Single Sign-On (WSSO) authentication

WSSO is RADIUS-based authentication that passes the user's user group memberships to the FortiGate. For each user, the RADIUS server must provide user group information in the Fortinet-Group-Name attribute. This information is stored in the server's database. After the user authenticates, security policies provide access to network services based on user groups.

1. Configure the RADIUS server to return the Fortinet-Group-Name attribute for each user.
2. Configure the FortiGate to access the RADIUS server, as described in [WPA2 Enterprise authentication on page 1432](#).
3. Create firewall user groups on the FortiGate with the same names as the user groups listed in the RADIUS database. Leave the groups empty.
4. In the SSID choose WPA2-Enterprise authentication. In the **Authentication** field, select **RADIUS Server** and choose the RADIUS server that you configured.
5. Create security policies as needed, using user groups (**Source User(s)** field) to control access.

When a user authenticates by WSSO, the firewall monitor **Monitor > Firewall User Monitor** shows the authentication method as WSSO.

Assigning WiFi users to VLANs dynamically

Some enterprise networks use Virtual LANs (VLANs) to separate traffic. In this environment, to extend network access to WiFi users might appear to require multiple SSIDs. But it is possible to automatically assign each user to their appropriate VLAN from a single SSID. To accomplish this requires RADIUS authentication that passes the appropriate VLAN ID to the FortiGate by RADIUS attributes. Each user's VLAN assignment is stored in the user database of the RADIUS server.

1. Configure the RADIUS server to return the following attributes for each user:
 - Tunnel-Type (value: VLAN)
 - Tunnel-Medium-Type (value: IEEE-802)
 - Tunnel_Private-Group-Id (value: the VLAN ID for the user's VLAN)
2. Configure the FortiGate to access the RADIUS server.

3. Configure the SSID with WPA2-Enterprise authentication. In the **Authentication** field, select **RADIUS Server** and choose the RADIUS server that you will use.
4. Create VLAN subinterfaces on the SSID interface, one for each VLAN. Set the VLAN ID of each as appropriate. You can do this on the **Network > Interfaces** page.
5. Enable Dynamic VLAN assignment for the SSID. For example, if the SSID interface is "office", enter:

```
config wireless-controller vap
  edit office
    set dynamic-vlan enable
  end
```
6. Create security policies for each VLAN. These policies have a WiFi VLAN subinterface as **Incoming Interface** and allow traffic to flow to whichever **Outgoing Interface** these VLAN users will be allowed to access.

MAC-based authentication

Wireless clients can also be supplementally authenticated by MAC address. A RADIUS server stores the allowed MAC address for each client and the wireless controller checks the MAC address independently of other authentication methods.

MAC-based authentication must be configured in the CLI. In the following example, MAC-based authentication is added to an existing access point "vap1" to use RADIUS server hq_radius (configured on the FortiGate):

```
config wireless-controller vap
  edit vap1
    set radius-mac-auth enable
    set radius-mac-auth-server hq_radius
  end
```

Authenticating guest WiFi users

The FortiOS Guest Management feature enables you to easily add guest accounts to your FortiGate unit. These accounts are authenticate guest WiFi users for temporary access to a WiFi network managed by a FortiGate unit. To implement guest access, you need to

1. Go to **User & Device > User Groups** and create one or more guest user groups.
2. Go to **User & Device > Guest Management** to create guest accounts. You can print the guest account credentials or send them to the user as an email or SMS message.
3. Go to **WiFi & Switch Controller > SSID** and configure your WiFi SSID to use captive portal authentication. Select the guest user group(s) that you created.

Guest users can log into the WiFi captive portal with their guest account credentials until the account expires. For more detailed information about creating guest accounts, see "Managing Guest Access" in the Authentication chapter of the FortiOS Handbook.

Configuring firewall policies for the SSID

For users on the WiFi LAN to communicate with other networks, firewall policies are required. This section describes creating a WiFi network to Internet policy.

Before you create firewall policies, you need to define any firewall addresses you will need.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Name	Enter a name for the address, wifi_net for example.
Type	Select Subnet .
Subnet / IP Range	Enter the subnet address, 10.10.110.0/24 for example.
Interface	Select the interface where this address is used, e.g., example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
edit "wifi_net"
set associated-interface "example_wifi"
set subnet 10.10.110.0 255.255.255.0
end
```

To create a firewall policy - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. In **Incoming Interface**, select the wireless interface.
3. In **Source Address**, select the address of your WiFi network, wifi_net for example.
4. In **Outgoing Interface**, select the Internet interface, for example, port1.
5. In **Destination Address**, select **All**.
6. In **Service**, select **ALL**, or select the particular services that you want to allow, and then select the right arrow button to move the service to the **Selected Services** list.
7. In **Schedule**, select **always**, unless you want to define a schedule for limited hours.
8. In **Action**, select **ACCEPT**.
9. Select **Enable NAT**.
10. Optionally, set up UTM features for wireless users.
11. Select **OK**.

To create a firewall policy - CLI

```
config firewall policy
edit 0
set srcintf "example_wifi"
set dstintf "port1"
set srcaddr "wifi_net"
set dstaddr "all"
set action accept
set schedule "always"
set service "ALL"
set nat enable
end
```

Configuring the built-in access point on a FortiWiFi unit

Both FortiGate and FortiWiFi units have the WiFi controller feature. If you configure a WiFi network on a FortiWiFi unit, you can also use the built-in wireless capabilities in your WiFi network as one of the access points.

If Virtual Domains are enabled, you must select the VDOM to which the built-in access point belongs. You do this in the CLI. For example:

```
config wireless-controller global
    set local-radio-vdom vdom1
end
```

To configure the FortiWiFi unit's built-in WiFi access point

1. Go to **WiFi Controller > Local WiFi Radio**.
2. Make sure that **Enable WiFi Radio** is selected.
3. In **SSID**, if you do not want this AP to carry all SSIDs, select **Select SSIDs** and then select the required SSIDs.
4. Optionally, adjust the **TX Power** slider.
If you have selected your location correctly (see [Configuring the built-in access point on a FortiWiFi unit on page 1435](#)), the 100% setting corresponds to the maximum power allowed in your region.
5. If you do not want the built-in WiFi radio to be used for rogue scanning, select **Do not participate in Rogue AP scanning**.
6. Select **OK**.

If you want to connect external APs, such as FortiAP units, see the next chapter, [Access point deployment](#).

Access point deployment

This chapter describes how to configure access points for your wireless network.

Overview

FortiAP units discover WiFi controllers. The administrator of the WiFi controller authorizes the FortiAP units that the controller will manage.

In most cases, FortiAP units can find WiFi controllers through the wired Ethernet without any special configuration. Review the following section, [Access point deployment on page 1437](#), to make sure that your method of connecting the FortiAP unit to the WiFi controller is valid. Then, you are ready to follow the procedures in [Access point deployment on page 1437](#).

If your FortiAP units are unable to find the WiFi controller, refer to [Access point deployment on page 1437](#) for detailed information about the FortiAP unit's controller discovery methods and how you can configure them.

Network topology for managed APs

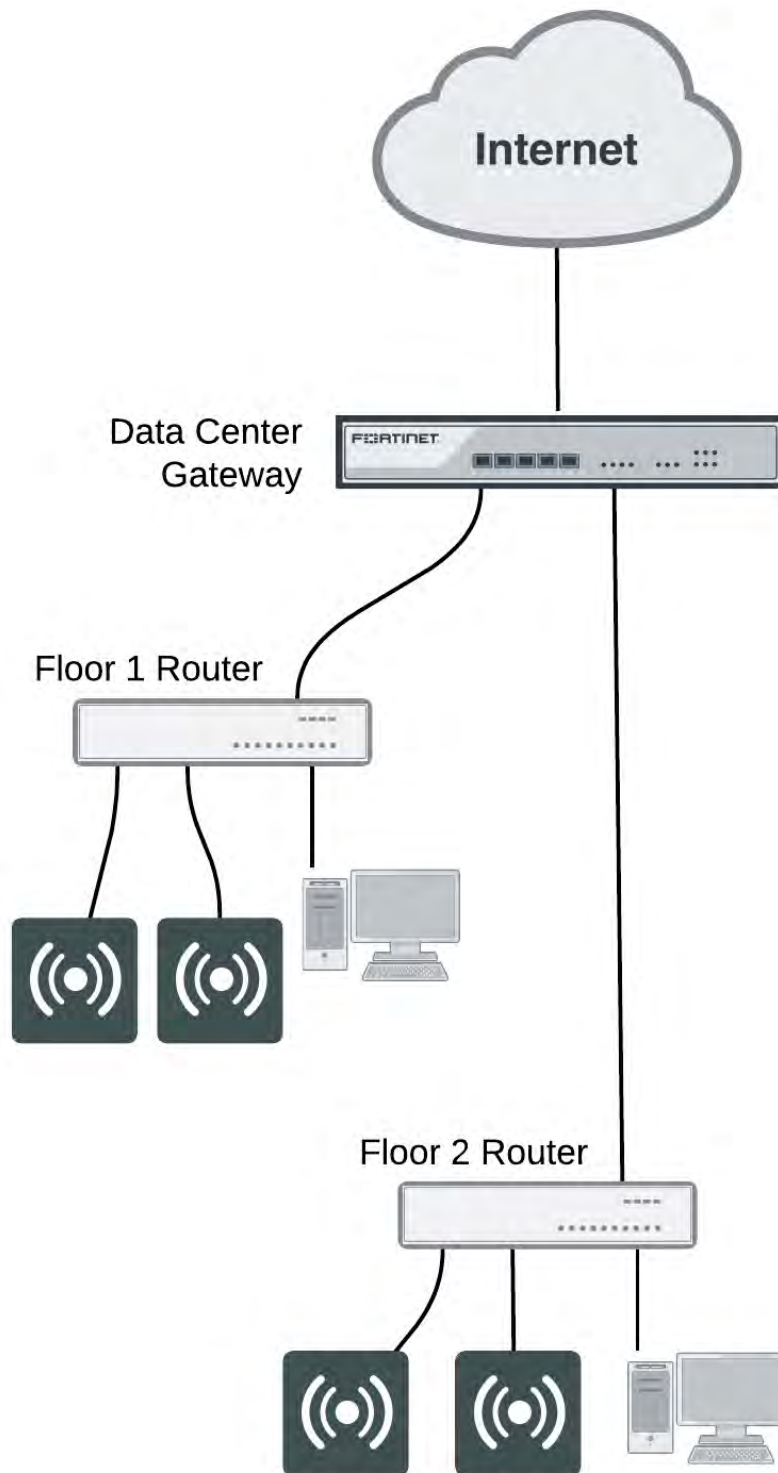

The FortiAP unit can be connected to the FortiGate unit in any of the following ways:

Direct connection: The FortiAP unit is directly connected to the FortiGate unit with no switches between them. This configuration is common for locations where the number of FortiAP's matches up with the number of 'internal' ports available on the FortiGate. In this configuration the FortiAP unit requests an IP address from the FortiGate unit, enters discovery mode and should quickly find the FortiGate WiFi controller. This is also known as a wirecloset deployment. See "Wirecloset and Gateway deployments" below.

Wirecloset deployment

Switched Connection: The FortiAP unit is connected to the FortiGate WiFi controller by an Ethernet switch operating in L2 switching mode or L3 routing mode. There must be a routable path between the FortiAP unit and the FortiGate unit and ports 5246 and 5247 must be open. This is also known as a gateway deployment. See Gateway Deployment below.

Gateway Deployment

Connection over WAN: The FortiGate WiFi controller is off-premises and connected by a VPN tunnel to a local FortiGate. In this method of connectivity its best to configure each FortiAP with the static IP address of the WiFi controller. Each FortiAP can be configured with three WiFi controller IP addresses for redundant failover. This is also known as a datacenter remote management deployment. See Remote deployment below.

Remote deployment

Discovering and authorizing APs

After you prepare your FortiGate unit, you can connect your APs to discover them using the discovery methods described earlier. To prepare the FortiGate unit, you need to

- Configure the network interface to which the AP will connect.
- Configure DHCP service on the interface to which the AP will connect.
- Optionally, preauthorize FortiAP units. They will begin to function when connected.
- Connect the AP units and let the FortiGate unit discover them.
- Enable each discovered AP and configure it or assign it to an AP profile.

Configuring the network interface for the AP unit

The interface to which you connect your wireless access point needs an IP address. No administrative access, DNS Query service or authentication should be enabled.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the interface to which the AP unit connects.
2. Set **Addressing Mode** to **Dedicate to Extension Device**.
3. Enter the IP address and netmask to use.
This FortiGate unit automatically configures a DHCP server on the interface that will assign the remaining higher addresses up to .254 to FortiAP units. For example, if the IP address is 10.10.1.100, the FortiAP units will be assigned 10.10.1.101 to 10.10.1.254. To maximize the available addresses, use the .1 address for the interface: 10.10.1.1, for example.
4. Select **OK**.

To configure the interface for the AP unit - CLI

In the CLI, you must configure the interface IP address and DHCP server separately.

```
config system interface
  edit port3
    set mode static
    set ip 10.10.70.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set interface "dmz"
    config ip-range
      edit 1
        set end-ip 10.10.70.254
        set start-ip 10.10.70.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
  end
```

The optional `vci-match` and `vci-string` fields ensure that the DHCP server will provide IP addresses only to FortiAP units.

Pre-authorizing a FortiAP unit

If you enter the FortiAP unit information in advance, it is authorized and will begin to function when it is connected.

To pre-authorize a FortiAP unit

1. Go to **WiFi & Switch Controller > Managed FortiAPs** and select **Create New**.
On some models the **WiFi Controller** menu is called **WiFi & Switch Controller**.
2. Enter the **Serial Number** of the FortiAP unit.
3. Configure the **Wireless Settings** as required.
4. Select **OK**.

Enabling and configuring a discovered AP

Within two minutes of connecting the AP unit to the FortiGate unit, the discovered unit should be listed on **WiFi Controller > Managed FortiAPs** page. After you select the unit, you can authorize, edit or delete it.

Discovered access point unit

<div> + Create New Edit Delete Refresh Authorize </div>									
<div> AP Radio Managed FortiAPs 0/32 </div>									
Mesh	Access Point	State	Connected Via	SSIDs	Channel	Clients	OS Version	FortiAP Profile	
	FP221C3X14019926	?	192.168.2.2	Radio 1: Radio 2: Student-net	Radio1: 0 Radio2: 0	Radio 1: 0 Radio 2: 0		FAP221C-default	

When you authorize (enable) a FortiAP unit, it is configured by default to use the default FortiAP profile (determined by model). You can create and select a different profile if needed. The FortiAP Profile defines the entire configuration for the AP.

To add and configure the discovered AP unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
This configuration also applies to local WiFi radio on FortiWiFi models.
2. Select the FortiAP unit from the list and edit it.
3. Optionally, enter a **Name**. Otherwise, the unit will be identified by serial number.
4. Select **Authorize**.
5. Select a **FortiAP Profile**.
6. Select **OK**.

The physical access point is now added to the system. If the rest of the configuration is complete, it should be possible to connect to the wireless network through the AP.

To add the discovered AP unit - CLI

First get a list of the discovered access point unit serial numbers:

```
get wireless-controller wtp
```

Add a discovered unit and associate it with AP-profile1, for example:

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set admin enable
    set wtp-profile AP-profile1
  end
```

To view the status of the added AP unit

```
config wireless-controller wtp
  edit FAP22A3U10600118
  get
```

The `join-time` field should show a time, not "N/A". See the preceding web-based manager procedure for more information.

Disable automatic discovery of unknown FortiAPs

By default, the FortiGate adds newly discovered FortiAPs to the Managed FortiAPs list, awaiting the administrator's authorization. Optionally, you can disable this automatic registration function to avoid adding unknown FortiAPs. A FortiAP will be registered and listed only if its serial number has already been added manually to the Managed FortiAPs list. AP registration is configured on each interface.

To disable automatic discovery and registration, enter the following command:

```
config system interface
  edit port15
```

```
set ap-discover disable
end
```

Automatic authorization of extension devices

To simplify adding FortiAP or FortiSwitch devices to your network, you can enable automatic authorization of devices as they are connected, instead of authorizing each one individually.

This feature is only configurable in the CLI.

To enable automatic authorization on all dedicated interfaces

```
config system global
set auto-auth-extension-device enable
end
```

To enable automatic authorization per-interface

```
config system interface
edit <port>
set auto-auth-extension-device enable
end
```

Assigning the same profile to multiple FortiAP units

The same profile can now be applied to multiple managed FortiAP units at the same time. To do this, do the following:

1. Go to **WiFi & Switch Controller > Managed FortiAPs** to view the AP list.
2. Select all FortiAP units you wish to apply the profile to.
3. Right click on one of the selected FortiAPs and select **Assign Profile**.
4. Choose the profile you wish to apply.

Overriding the FortiAP Profile

In the FortiAP configuration **WiFi & Switch Controller > Managed FortiAPs**, there several radio settings under **Override Radio 1** and **Override Radio 2** to choose a value independently of the FortiAP Profile setting. When each of the radios are disabled, you will see what the FortiAP Profile has each of the settings configured to.

Band	The available options depend on the capability of the radio. Overriding Band also overrides Channels . Make appropriate settings in Channels .
Channels	Choose channels. The available channels depend on the Band.
TX Power Control	If you enable Auto , adjust to set the power range in dBm. If you enable Manual , adjust the slider. The 100% setting is the maximum power permitted in your region. See Configuring a WiFi LAN on page 1414 .
SSIDs	Select between Auto or Manual . Selecting Auto eliminates the need to re-edit the profile when new SSIDs are created. However, you can still select SSIDs individually using Manual .

To override radio settings in the CLI

In this example, Radio 1 is set to 802.11n on channel 11, regardless of the profile setting.

```
config wireless-controller wtp
edit FP221C3X14019926
config radio-1
set override-band enable
set band 802.11n
set override-channel enable
set channel 11
end
```

Override settings are available for band, channel, vaps (SSIDs), and txpower.

Outside of configuring radio settings, you can also override FortiAP LED state, WAN port mode, IP Fragmentation prevention method, spectrum analysis, split tunneling, and login password settings.

Accessing the FortiAP CLI through the FortiGate unit

Enable remote login for the FortiAP. In the FortiAP Profile for this FortiAP, enable remote access.

Connecting to the FortiAP CLI

The FortiAP unit has a CLI through which some configuration options can be set. You can access the CLI using Telnet.

To access the FortiAP unit CLI through the FortiAP Ethernet port

1. Connect your computer to the FortiAP Ethernet interface, either directly with a cross-over cable or through a separate switch or hub.
2. Change your computer's IP address to 192.168.1.3
3. Telnet to IP address 192.168.1.2.
Ensure that FortiAP is in a private network with no DHCP server for the static IP address to be accessible.
4. Login with user name admin and no password.
5. Enter commands as needed.
6. Optionally, use the `passwd` command to assign an administrative password for better security.
7. Save the configuration by entering the following command:

```
cfg -c .
```

8. Unplug the FortiAP and then plug it back in, in order for the configuration to take effect

Accessing the FortiAP CLI through the FortiGate

After the FortiAP has been installed, physical access to the unit might be inconvenient. You can access a connected FortiAP unit's CLI through the FortiGate unit that controls it.

To enable remote access to the FortiAP CLI

In the CLI, edit the FortiAP Profile that applies to this FortiAP.

```
config wireless-controller wtp-profile
edit FAP221C-default
set allowaccess telnet
end
```

FortiAP now supports HTTPS and SSH administrative access, as well as HTTP and Telnet. Use the command above to set administrative access to `telnet`, `http`, `https`, or `ssh`.

To access the FortiAP unit CLI through the FortiGate unit - GUI

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. In the list, right-click the FortiAP unit and select **>_Connect to CLI**.
A detached Console window opens.
3. At the FortiAP login prompt, enter `admin`. When you are finished using the FortiAP CLI, enter `exit`.

To access the FortiAP unit CLI through the FortiGate unit - CLI

1. Use the FortiGate CLI `execute telnet` command to access the FortiAP. For example, if the FortiAP unit IP address is 192.168.1.2, enter:

```
execute telnet 192.168.1.2
```
 2. At the FortiAP login prompt, enter `admin`. When you are finished using the FortiAP CLI, enter `exit`.
-

When a WiFi controller has taken control of the FortiAP unit, Telnet access to the FortiAP unit's CLI is no longer available.

Checking and updating FortiAP unit firmware

You can view and update the FortiAP unit's firmware from the FortiGate unit that acts as its WiFi controller.

Checking the FortiAP unit firmware version

Go to **WiFi & Switch Controller > Managed FortiAPs** to view the list of FortiAP units that the FortiGate unit can manage. The **OS Version** column shows the current firmware version running on each AP.

Updating FortiAP firmware from the FortiGate unit

You can update the FortiAP firmware using either the web-based manager or the CLI. Only the CLI method can update all FortiAP units at once.

To update FortiAP unit firmware - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Right-click the FortiAP unit in the list and select **Upgrade Firmware**.
or
Edit the FortiAP entry and select **Upgrade from File** in **FortiAP OS Version**.
3. Select **Browse** and locate the firmware upgrade file.
4. Select **OK**.
5. When the upgrade process completes, select **OK**.
The FortiAP unit restarts.

To update FortiAP unit firmware - CLI

1. Upload the FortiAP image to the FortiGate unit.

For example, the Firmware file is FAP_22A_v4.3.0_b0212_fortinet.out and the server IP address is 192.168.0.100.

```
execute wireless-controller upload-wtp-image tftp FAP_22A_v4.3.0_b0212_fortinet.out
192.168.0.100
```

If your server is FTP, change `tftp` to `ftp`, and if necessary add your user name and password at the end of the command.

2. Verify that the image is uploaded:

```
execute wireless-controller list-wtp-image
```

3. Upgrade the FortiAP units:

```
exec wireless-controller reset-wtp all
```

If you want to upgrade only one FortiAP unit, enter its serial number instead of `all`.

Updating FortiAP firmware from the FortiAP unit

You can connect to a FortiAP unit's internal CLI to update its firmware from a TFTP server on the same network. This method does not require access to the wireless controller.

1. Place the FortiAP firmware image on a TFTP server on your computer.
2. Connect the FortiAP unit to a separate private switch or hub or directly connect to your computer via a cross-over cable.
3. Change your computer's IP address to 192.168.1.3.
4. Telnet to IP address 192.168.1.2.
This IP address is overwritten if the FortiAP is connected to a DHCP environment. Ensure that the FortiAP unit is in a private network with no DHCP server.
5. Login with the username "admin" and no password.
6. Enter the following command.

For example, the FortiAP image file name is FAP_22A_v4.3.0_b0212_fortinet.out.

```
restore FAP_22A_v4.3.0_b0212_fortinet.out 192.168.1.3
```

Advanced WiFi controller discovery

A FortiAP unit can use any of six methods to locate a controller. By default, FortiAP units cycle through all six of the discovery methods. In most cases there is no need to make configuration changes on the FortiAP unit.

There are exceptions. The following section describes the WiFi controller discovery methods in more detail and provides information about configuration changes you might need to make so that discovery will work.

Controller discovery methods

There are six methods that a FortiAP unit can use to discover a WiFi controller. Below is the list of AC discovery methods used in sequence, if the FortiAP's discovery type is set to auto:

1(static) → 2(dhcp) → 3(dns) → 7(forticloud) → 5(multicast) → 6(broadcast)

For every discovery type, FortiAP sends out discovery requests and sets a timer, an interval defined as a random number of seconds (between 2-180, default is 5 seconds), which is set via the CLI:

CLI syntax

```
config wireless-controller timers
    set discovery-interval 5
end
```

After the timeout is reached, FortiAP sends out another discovery request, up to a maximum of 3 times.

After about 3 - 15 seconds, if FortiAP has no AC connection, it will switch to another discovery type and repeat the above process until the last one (**broadcast**) fails, which will lead to SULKING state.

After about 30 seconds, FortiAP will go into an AC_IP_DISCOVER state. After the AC IP is found, it will go to IDLE state, and will eventually go to the DISCOVERY state, and repeat the above process again.

Note that, while the process above is showcasing the auto discovery method, it's recommended to set the AC_DISCOVERY_TYPE to your used method in order to reduce downtime.

Static IP configuration

If FortiAP and the controller are not in the same subnet, broadcast and multicast packets cannot reach the controller. The admin can specify the controller's static IP on the AP unit. The AP unit sends a discovery request message in unicast to the controller. Routing must be properly configured in both directions.

To specify the controller's IP address on a FortiAP unit

```
cfg -a AC_IPADDR_1="192.168.0.100"
```

By default, the FortiAP unit receives its IP address, netmask, and gateway address by DHCP. If you prefer, you can assign these statically.

To assign a static IP address to the FortiAP unit

```
cfg -a ADDR_MODE=STATIC
cfg -a AP_IPADDR="192.168.0.100"
cfg -a AP_NETMASK="255.255.255.0"
cfg -a IPGW=192.168.0.1
cfg -c
```

For information about connecting to the FortiAP CLI, see [Connecting to the FortiAP CLI on page 1444](#).

DHCP

If you use DHCP to assign an IP address to your FortiAP unit, you can also provide the WiFi controller IP address at the same time. This is useful if the AP is located remotely from the WiFi controller and other discovery techniques will not work.

When you configure the DHCP server, configure Option 138 to specify the WiFi controller IP address. You need to convert the address into hexadecimal. Convert each octet value separately from left to right and concatenate them. For example, 192.168.0.1 converts to C0A80001.

If Option 138 is used for some other purpose on your network, you can use a different option number if you configure the AP units to match.

To change the FortiAP DHCP option code

To use option code 139 for example, enter

```
cfg -a AC_DISCOVERY_DHCP_OPTION_CODE=139
```

For information about connecting to the FortiAP CLI, see [Connecting to the FortiAP CLI on page 1444](#).

DNS

The access point can discover controllers through your domain name server (DNS). For the access point to do so, you must configure your DNS to return controller IP addresses in response. Allow DNS lookup of the hostname configured in the AP by using the AP parameter "AC_HOSTNAME_1".

FortiCloud

The access point can discover FortiCloud by doing a DNS lookup of the hardcoded FortiCloud AP controller hostname "apctrl1.fortinet.com". The forticloud AC discovery technique finds the AC info from apctrl1.fortinet.com using HTTPS.

FortiCloud APController: apctrl1.fortinet.com:443 208.91.113.187:443

Broadcast request

The AP unit broadcasts a discovery request message to the network and the controller replies. The AP and the controller must be in the same broadcast domain. No configuration adjustments are required.

Multicast request

The AP unit sends a multicast discovery request and the controller replies with a unicast discovery response message. The AP and the controller do not need to be in the same broadcast domain if multicast routing is properly configured.

The default multicast destination address is 224.0.1.140. It can be changed through the CLI. The address must be same on the controller and AP.

To change the multicast address on the controller

```
config wireless-controller global
  set discovery-mc-addr 224.0.1.250
end
```

To change the multicast address on a FortiAP unit

```
cfg -a AC_DISCOVERY_MC_ADDR="224.0.1.250"
```

For information about connecting to the FortiAP CLI, see [Advanced WiFi controller discovery on page 1446](#).

Wireless client load balancing for high-density deployments

Wireless load balancing allows your wireless network to distribute wireless traffic more efficiently among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- Access Point Hand-off - the wireless controller signals a client to switch to another access point.
- Frequency Hand-off - the wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Load balancing is not applied to roaming clients.

Access point hand-off

Access point handoff wireless load balancing involves the following:

- If the load on an access point (ap1) exceeds a threshold (of for example, 30 clients) then the client with the weakest signal will be signaled by wireless controller to drop off and join another nearby access point (ap2).
- When one or more access points are overloaded (for example, more than 30 clients) and a new client attempts to join a wireless network, the wireless controller selects the least busy access point that is closest to the new client and this access point is the one that responds to the client and the one that the client joins.

Frequency hand-off or band-steering

Encouraging clients to use the 5GHz WiFi band if possible enables those clients to benefit from faster interference-free 5GHz communication. The remaining 2.4GHz clients benefit from reduced interference.

The WiFi controller probes clients to determine their WiFi band capability. It also records the RSSI (signal strength) for each client on each band.

If a new client attempts to join the network, the controller looks up that client's MAC address in its wireless device table and determines if it's a dual band device. If it is not a dual band device, then its allowed to join. If it is a dual band device, then its RSSI on 5GHz is used to determine whether the device is close enough to an access point to benefit from movement to 5GHz frequency.

If both conditions of 1) dual band device and 2) RSSI value is strong, then the wireless controller does not reply to the join request of the client. This forces the client to retry a few more times and then timeout and attempt to join the same SSID on 5GHz. Once the Controller see this new request on 5GHz, the RSSI is again measured and the client is allowed to join. If the RSSI is below threshold, then the device table is updated and the controller forces the client to timeout again. A client's second attempt to connect on 2.4GHz will be accepted.

Configuration

From the web-based manager, edit a custom AP profile and select **Frequency Handoff** and **AP Handoff** as required for each radio on the AP.

From the CLI, you configure wireless client load balancing thresholds for each custom AP profile. Enable access point hand-off and frequency hand-off separately for each radio in the custom AP profile.

```
config wireless-controller wtp-profile
edit new-ap-profile
set handoff-rssi <rssi_int>
set handoff-sta-thresh <clients_int>
config radio-1
set frequency-handoff {disable | enable}
set ap-handoff {disable | enable}
end
config radio-2
set frequency-handoff {disable | enable}
set ap-handoff {disable | enable}
end
end
```

Where:

- `handoff-rssi` is the RSSI threshold. Clients with a 5 GHz RSSI threshold over this value are load balanced to the 5GHz frequency band. Default is 25. Range is 20 to 30.

- `handoff-sta-thresh` is the access point handoff threshold. If the access point has more clients than this threshold it is considered busy and clients are changed to another access point. Default is 30, range is 5 to 25.
- `frequency-handoff` enable or disable frequency handoff load balancing for this radio. Disabled by default.
- `ap-handoff` enable or disable access point handoff load balancing for this radio. Disabled by default.

Frequency handoff must be enabled on the 5GHz radio to learn client capability.

FortiAP Groups

FortiAP Groups facilitate the application of FortiAP profiles to large numbers of FortiAPs. A FortiAP can belong to no more than one FortiAP Group. A FortiAP Group can include only one model of FortiAP.

Through the VLAN pool feature, a FortiAP Group can be associated with a VLAN to which WiFi clients will be assigned. For more on VLAN pool assignment, see [VLAN assignment by VLAN pool](#).

FortiAP groups are only configurable in the CLI Console.

To create a FortiAP group - CLI

In this example, `wtp-group-1` is created for a FortiAP-221C and one member device is added.

```
config wireless-controller wtp-group
  edit wtp-group-1
    set platform-type 221C
    config wtp-list
      edit FP221C3X14019926
    end
  end
end
```

LAN port options

Some FortiAP models have one or more LAN interfaces that can provide wired network access. LAN ports can be

- bridged to the incoming WAN interface
- bridged to one of the WiFi SSIDs that the FortiAP unit carries
- connected by NAT to the incoming WAN interface

There are some differences among FortiAP models.

Models like 11C and 14C have one port labeled WAN and one or more ports labeled LAN. By default, the LAN ports are offline. You can configure LAN port operation in the FortiAP Profile in the GUI (**Wireless Controller > FortiAP Profiles**) or in the CLI (`config wireless-controller wtp-profile`, `config lan` subcommand).

Models like 320C, 320B, 112D, and 112B have two ports, labeled LAN1 and LAN2. LAN1 acts as a WAN port connecting the FortiAP to a FortiGate or FortiCloud. By default, LAN2 is bridged to LAN1. Other modes of LAN2 operation must be enabled in the CLI:

```
config wireless-controller wtp-profile
  edit <profile_name>
    set wan-port-mode wan-lan
  end
```

By default `wan-port-mode` is set to `wan-only`.

When `wan-port-mode` is set to `wan-lan`, LAN2 Port options are available in the GUI and the CLI the same as the other FortiAP models that have labeled WAN and LAN ports.

Bridging a LAN port with an SSID

Bridging a LAN port with a FortiAP SSID combines traffic from both sources to provide a single broadcast domain for wired and wireless users.

In this configuration

- The IP addresses for LAN clients come from the DHCP server that serves the wireless clients.
- Traffic from LAN clients is bridged to the SSID's VLAN. Dynamic VLAN assignment for hosts on the LAN port is not supported.
- Wireless and LAN clients are on the same network and can communicate locally, via the FortiAP.
- Any host connected to the LAN port will be taken as authenticated. RADIUS MAC authentication for hosts on the LAN port is not supported.

For configuration instructions, see [LAN port options on page 1450](#).

Bridging a LAN port with the WAN port

Bridging a LAN port with the WAN port enables the FortiAP unit to be used as a hub which is also an access point.

In this configuration

- The IP addresses for LAN clients come from the WAN directly and will typically be in the same range as the AP itself.
- All LAN client traffic is bridged directly to the WAN interface.
- Communication between wireless and LAN clients can only occur if a policy on the FortiGate unit allows it.

For configuration instructions, see [LAN port options on page 1450](#).

Configuring FortiAP LAN ports

You can configure FortiAP LAN ports for APs in a FortiAP Profile. A profile applies to APs that are the same model and share the same configuration. If you have multiple models or different configurations, you might need to create several FortiAP Profiles. For an individual AP, it is also possible to override the profile settings.

To configure FortiAP LAN ports - web-based manager

1. If your FortiAP unit has LAN ports, but no port labeled WAN (models 320C, 320B, 112D, and 112B for example), enable LAN port options in the CLI:

```
config wireless-controller wtp-profile
  edit <profile_name>
    set wan-port-mode wan-lan
  end
```
2. Go to **WiFi & Switch Controller > FortiAP Profiles**.
3. Edit the default profile for your FortiAP model or select **Create New**.
4. If you are creating a new profile, enter a **Name** and select the correct **Platform** (model).
5. Select SSIDs.
6. In the **LAN Port** section, set **Mode** to **Bridge to** and select an SSID or **WAN Port** as needed.
On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually.

Enable each port that you want to use and select an SSID or **WAN Port** as needed.

7. Select **OK**.

Be sure to select this profile when you authorize your FortiAP units.

To configure FortiAP LAN ports - CLI

In this example, the default FortiAP-11C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
  edit FAP11C-default
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

In this example, the default FortiAP-28C profile is configured to bridge LAN port1 to the office SSID and to bridge the other LAN ports to the WAN port.

```
config wireless-controller wtp-profile
  edit FAP28C-default
    config lan
      set port1-mode bridge-to-ssid
      set port1-ssid office
      set port2-mode bridge-to-wan
      set port3-mode bridge-to-wan
      set port4-mode bridge-to-wan
      set port5-mode bridge-to-wan
      set port6-mode bridge-to-wan
      set port7-mode bridge-to-wan
      set port8-mode bridge-to-wan
    end
  end
end
```

In this example, the default FortiAP-320C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
  edit FAP320C-default
    set wan-port-mode wan-lan
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

To configure FortiAP unit LAN ports as a FortiAP Profile override - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Select the FortiAP unit from the list and select **Edit**.
3. Select the **FortiAP Profile**, if this has not already been done.
4. In the **LAN Port** section, select **Override**.
The options for **Mode** are shown.
5. Set **Mode** to **Bridge to** and select an SSID or **WAN Port**, or **NAT to WAN** as needed.
On some models with multiple LAN ports, you can set **Mode** to **Custom** and configure the LAN ports individually.

Enable and configure each port that you want to use.

6. Select OK.

To configure FortiAP unit LAN ports as a FortiAP Profile override - CLI

In this example, a FortiAP unit's configuration overrides the FortiAP Profile to bridge the LAN port to the office SSID.

```
config wireless-controller wtp
  edit FP320C3X14020000
    set wtp-profile FAP320C-default
    set override-wan-port-mode enable
    set wan-port-mode wan-lan
    set override-lan enable
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

Preventing IP fragmentation of packets in CAPWAP tunnels

A common problem with controller-based WiFi networks is reduced performance due to IP fragmentation of the packets in the CAPWAP tunnel.

Fragmentation can occur because of CAPWAP tunnel overhead increasing packet size. If the original wireless client packets are close to the maximum transmission unit (MTU) size for the network (usually 1500 bytes for Ethernet networks unless jumbo frames are used) the resulting CAPWAP packets may be larger than the MTU, causing the packets to be fragmented. Fragmenting packets can result in data loss, jitter, and decreased throughput.

The FortiOS/FortiAP solution to this problem is to cause wireless clients to send smaller packets to FortiAP devices, resulting in 1500-byte CAPWAP packets and no fragmentation. The following options configure CAPWAP IP fragmentation control:

```
config wireless-controller wtp-profile
  edit FAP321C-default
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

By default, `tcp-mss-adjust` is enabled, `icmp-unreachable` is disabled, and `tun-mtu-uplink` and `tun-mtu-downlink` are set to 0.

To set `tun-mtu-uplink` and `tun-mtu-downlink`, use the default TCP MTU value of 1500. This default configuration prevents packet fragmentation because the FortiAP unit limits the size of TCP packets received from wireless clients so the packets don't have to be fragmented before CAPWAP encapsulation.

The `tcp-mss-adjust` option causes the FortiAP unit to limit the maximum segment size (MSS) of TCP packets sent by wireless clients. The FortiAP does this by adding a reduced MSS value to the SYN packets sent by the FortiAP unit when negotiating with a wireless client to establish a session. This results in the wireless client sending packets that are smaller than the `tun-mtu-uplink` setting, so that when the CAPWAP headers are added, the CAPWAP packets have an MTU that matches the `tun-mtu-uplink` size.

The `icmp-unreachable` option affects all traffic (UDP and TCP) between wireless clients and the FortiAP unit. This option causes the FortiAP unit to drop packets that have the "Don't Fragment" bit set in their IP header and that are large enough to cause fragmentation and then send an ICMP packet -- type 3 "ICMP Destination unreachable" with code 4 "Fragmentation Needed and Don't Fragment was Set" back to the wireless controller. This should cause the wireless client to send smaller TCP and UDP packets.

Overriding IP fragmentation settings on a FortiAP

If the FortiAP Profile settings for IP fragmentation are not appropriate for a particular FortiAP, you can override the settings on that specific unit.

```
config wireless-controller wtp
  edit FAP321C3X14019926
    set override-ip-fragment enable
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

LED options

Optionally, the status LEDs on the FortiAP can be kept dark. This is useful in dormitories, classrooms, hotels, medical clinics, hospitals where the lights might be distracting or annoying to occupants.

On the FortiGate, the LED state is controlled in the FortiAP Profile. By default the LEDs are enabled. The setting is CLI-only. For example, to disable the LEDs on FortiAP-221C units controlled by the FAP221C-default profile, enter:

```
config wireless-controller wtp-profile
  edit FAP221C-default
    set led-state disable
  end
```

You can override the FortiAP Profile LED state setting on an individual FortiAP using the CLI. For example, to make sure the LEDs are disabled on one specific unit, enter:

```
config wireless-controller wtp
  edit FAP221C3X14019926
    set override-led-state enable
    set led-state disable
  end
```

The LED state is also controllable from the FortiAP unit itself. By default, the FortiAP follows the FortiAP Profile setting.

LED Schedules

Use the command below (`led-schedule`) to assign recurring firewall schedules for illuminating LEDs on the FortiAP. This entry is only available when `led-state` is enabled, at which point LEDs will be visible when at least one of the schedules is valid.

Separate multiple schedule names with a space, as configured under `config firewall schedule group` and `config firewall schedule recurring`.

Syntax

```

config wireless-controller wtp-profile
  edit {name}
    set led-state {enable | disable}
    set led-schedules <name>
  next
end

```

CAPWAP bandwidth formula

The following section provides information on how to calculate the control plane CAPWAP traffic load in local bridging. The formula provided can help estimate the approximate package bandwidth cost. This is important for knowing precisely how much bandwidth is required on a WAN link for a centralized FortiGate managing hundreds of access points.

There are multiple factors that might affect the volume of CAPWAP control traffic, including the number of stations there are and large WiFi events.

The Ethernet/IP/UDP/CAPWAP uplink header cost should be approximately 66 bytes.

The tables below depict basic and commonly used optional CAPWAP bandwidth costs, on a per-AP basis.

Note the following:

- **STA:** The number of stations associated with the FortiAP.
- **ARP scan:** Finds hidden devices in your network.
- **VAP:** The number of VAPS held by the FortiAP.
- **Radio:** The number of radios (maximum of two) enabled by the FortiAP.

Basic per-AP CAPWAP bandwidth costs

Content	Time (seconds)	Payload (byte)	Package bandwidth cost (bps)
Echo Req	30	16	$(66+16)*8/30=21.86$
STA scan	30	$25+20*sta$	$(66+25+20*sta)*8/30=24.26+5.3*sta$
ARP scan	30	$25+18*sta$	$(66+25+18*sta)*8/30=24.26+4.8*sta$
STA CAP	30	$25+19*sta$	$(66+25+19*sta)*8/30=24.26+5.1*sta$
STA stats	1	$25+41*sta$	$(66+25+41*sta)*8/1=728.0+328.0*sta$
VAP stats	15	$40+18*vap$	$(66+40+18*vap)*8/15=56.53+9.6*vap$
Radio stats	15	$25+25*radio$	$(66+25+25*radio)*8/15=48.53+13.3*radio$
Total:			$908.7+343.2*sta+9.6*vap+13.3*radio$

Commonly used optional per-AP CAPWAP bandwidth costs

Content	Time (seconds)	Payload (byte)	Package bandwidth cost (bps)
AP scan	30	25+63*scanned-ap	$(66+25+63*\text{scanned-ap})*8/30=24.26+16.8*\text{scanned-ap}$
Total:			$932.96+343.2*\text{sta}+9.6*\text{vap}+13.3*\text{radio}+16.8*\text{scanned-ap}$

Enabling WIDS features, LLDP, MESH, FortiPresence, and Client Station Locating Service can lead to additional bandwidth consumption.

Example:

There are 100 FortiAPs, with 187 stations distributed among them. Each FortiAP holds five VAPs among their radios, and each enables two radios. The basic CAPWAP bandwidth cost would be:

$$908.7*100+343.2*187+9.6*5*100+13.3*2*100 = \mathbf{162.51\text{kbps}}$$

Additionally, if two FortiAPs enabled "AP scan", and suppose one scans 99 APs in each scan and the other scans 20 APs in each scan, the additional CAPWAP bandwidth cost would be:

$$(24.26+16.8*99)+(24.26+16.8*20) = \mathbf{2\text{kbps}}$$

Enabling LLDP protocol

You can enable the LLDP protocol in the FortiAP Profile via the CLI. Each FortiAP using that profile can then send back information about the switch and port that it is connected to.

To enable LLDP, enter the following:

```
config wireless-controller wtp-profile
  edit <profile-name>
    set lldp enable
  end
```

Wireless Mesh

The access points of a WiFi network are usually connected to the WiFi controller through Ethernet wiring. A wireless mesh eliminates the need for Ethernet wiring by connecting WiFi access points to the controller by radio. This is useful where installation of Ethernet wiring is impractical.

Overview of Wireless Mesh

The figure below shows a wireless mesh topology.

A wireless mesh is a multiple AP network in which only one FortiAP unit is connected to the wired network. The other FortiAPs communicate with the controller over a separate backhaul SSID that is not available to regular WiFi clients. The AP that is connected to the network by Ethernet is called the Mesh Root node. The backhaul SSID carries CAPWAP discovery, configuration, and other communications that would usually be carried on an Ethernet connection.

The root node can be a FortiAP unit or the built-in AP of a FortiWiFi unit. APs that serve regular WiFi clients are called Leaf nodes. Leaf APs also carry the mesh SSID for more distant leaf nodes. A leaf node can connect to the mesh SSID directly from the root node or from any of the other leaf nodes. This provides redundancy in case of an AP failure.

All access points in a wireless mesh configuration must have at least one of their radios configured to provide mesh backhaul communication. As with wired APs, when mesh APs start up they can be discovered by a FortiGate or FortiWiFi unit WiFi controller and authorized to join the network.

The backhaul SSID delivers the best performance when it is carried on a dedicated radio. On a two-radio FortiAP unit, for example, the 5GHz radio could carry only the backhaul SSID while the 2.4GHz radio carries one or more SSIDs that serve users. Background WiFi scanning is possible in this mode.

The backhaul SSID can also share the same radio with SSIDs that serve users. Performance is reduced because the backhaul and user traffic compete for the available bandwidth. Background WiFi scanning is not available in this mode. One advantage of this mode is that a two-radio AP can offer WiFi coverage on both bands.

Wireless mesh deployment modes

There are two common wireless mesh deployment modes:

Wireless Mesh	Access points are wirelessly connected to a FortiGate or FortiWiFi unit WiFi controller. WiFi users connect to wireless SSIDs in the same way as on non-mesh WiFi networks.
Wireless bridging	Two LAN segments are connected together over a wireless link (the backhaul SSID). On the leaf AP, the Ethernet connection can be used to provide a wired network. Both WiFi and wired users on the leaf AP are connected to the LAN segment to which the root AP is connected.

Firmware requirements

All FortiAP units that will be part of the wireless mesh network must be upgraded to FAP firmware version 5.0 build 003. FortiAP-222B units must have their BIOS upgraded to version 400012. The FortiWiFi or FortiGate unit used as the WiFi controller must be running FortiOS 5.0.

Types of wireless mesh

A WiFi mesh can provide access to widely-distributed clients. The root mesh AP which is directly connected to the WiFi controller can be either a FortiAP unit or the built-in AP of a FortiWiFi unit that is also the WiFi controller.

FortiAP units used as both mesh root AP and leaf AP

FortiWiFi unit as root mesh AP with FortiAP units as leaf APs

An alternate use of the wireless mesh functionality is as a point-to-point relay. Both wired and WiFi users on the leaf AP side are connected to the LAN segment on the root mesh side.

Point-to-point wireless mesh

Fast-roaming for mesh backhaul link

Mesh implementations for leaf FortiAP can perform background scan when the leaf AP is associated to root. Various options for background scanning can be configured with the CLI. See [Mesh variables on page 1562](#) for more details.

Configuring a meshed WiFi network

You need to:

- Create the mesh root SSID.
- Create the FortiAP profile.
- Configure mesh leaf AP units.
- Configure the mesh root AP, either a FortiWiFi unit's Local Radio or a FortiAP unit.
- Authorize the mesh branch/leaf units when they connect to the WiFi Controller.
- Create security policies.

This section assumes that the end-user SSIDs already exist.

Creating the mesh root SSID

The mesh route SSID is the radio backhaul that conveys the user SSID traffic to the leaf FortiAPs.

To configure the mesh root SSID

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter a **Name** for the WiFi interface.
3. In **Traffic Mode**, select **Mesh Downlink**.
4. Enter the **SSID**.
5. Set **Security Mode** to **WPA2 Personal** and enter the **Pre-shared key**.
Remember the key, you need to enter it into the configurations of the leaf FortiAPs.
6. Select **OK**.

Creating the FortiAP profile

Create a FortiAP profile for the meshed FortiAPs. If more than one FortiAP model is involved, you need to create a profile for each model. Typically, the profile is configured so that Radio 1 (5GHz) carries the mesh backhaul SSID while Radio 2 (2.4GHz) carries the SSIDs to which users connect.

The radio that carries the backhaul traffic must not carry other SSIDs. Use the **Select SSIDs** option and choose only the backhaul SSID. Similarly, the radio that carries user SSIDs, should not carry the backhaul. Use the **Select SSIDs** option and choose the networks that you want to provide.

For more information, see [Configuring a WiFi LAN on page 1414](#).

Configuring the mesh root FortiAP

The mesh root AP can be either a FortiWiFi unit's built-in AP or a FortiAP unit.

To enable a FortiWiFi unit's Local Radio as mesh root - web-based manager

1. Go to **WiFi Controller > Local WiFi Radio**.
2. Select **Enable WiFi Radio**.
3. In **SSID**, select **Select SSIDs**, then select the mesh root SSID.
4. Optionally, adjust **TX Power** or select **Auto Tx Power Control**.
5. Select **Apply**.

In a network with multiple wireless controllers, make sure that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > SSID** to change the SSID.

To configure a network interface for the mesh root FortiAP unit

1. On the FortiGate unit, go to **Network > Interfaces**.
2. Select the interface where you will connect the FortiAP unit, and edit it.
3. Make sure that **Role** is LAN.
4. In **Addressing mode**, select **Dedicated to Extension Device**.
5. In **IP/Network Mask**, enter an IP address and netmask for the interface.
DHCP will provide addresses to connected devices. To maximize the number of available addresses, the interface address should end with 1, for example 192.168.10.1.
6. Select **OK**.

At this point you can connect the mesh root FortiAP, as described next. If you are going to configure leaf FortiAPs through the wireless controller (see ["Configuring a meshed WiFi network" on page 1462](#)), it would be convenient to leave connecting the root unit for later.

To enable the root FortiAP unit

1. Connect the root FortiAP unit's Ethernet port to the FortiGate network interface that you configured for it.
2. Go to **WiFi & Switch Controller > Managed FortiAPs**.
If the root FortiAP unit is not listed, wait 15 seconds and select **Refresh**. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the root FortiAP unit and try again.
3. Right-click the FortiAP entry and choose your profile from the **Assign Profile** submenu.
4. Right-click the FortiAP entry and select **Authorize**.
Initially, the **State** of the FortiAP unit is **Offline**. Periodically click **Refresh** to update the status. Within about two minutes, the state changes to **Online**.
5. Select **OK**.
You might need to select Refresh a few times before the FortiAP shows as Online.

Configuring the leaf mesh FortiAPs

The FortiAP units that will serve as leaf nodes must be preconfigured. This involves changing the FortiAP unit internal configuration. You can do this by direct connection or through the FortiGate wireless controller.

Method 1: Direct connection to the FortiAP

1. Connect a computer to the FortiAP unit's Ethernet port. Configure the computer's IP as 192.168.1.3.
2. Telnet to 192.168.1.2. Login as admin. By default, no password is set.
3. Enter the following commands, substituting your own SSID and password (pre-shared key):

```
cfg -a MESH_AP_TYPE=1
cfg -a MESH_AP_SSID=fortinet.mesh.root
cfg -a MESH_AP_PASSWD=hardtoguess
cfg -c
exit
```

4. Disconnect the computer.
5. Power down the FortiAP.
6. Repeat the preceding steps for each branch FortiAP.

Method 2: Connecting through the FortiGate unit

1. Connect the branch FortiAP unit's Ethernet port to the FortiGate network interface that you configured for FortiAPs. Connect the FortiAP unit to a power source unless POE is used.
2. Go to **WiFi & Switch Controller > Managed FortiAPs**.
If the FortiAP unit is not listed, wait 15 seconds and select **Refresh**. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the FortiAP unit and try again.

3. Select the discovered FortiAP unit and authorize it. Click Refresh every 10 seconds until the State indicator is green.

4. Right-click the FortiAP and select **>_Connect to CLI**. The CLI Console window opens. Log in as "admin".

5. Enter the following commands, substituting your own SSID and password (pre-shared key):

```
cfg -a MESH_AP_TYPE=1
cfg -a MESH_AP_SSID=fortinet.mesh.root
cfg -a MESH_AP_PASSWD=hardtoguess
cfg -c
exit
```

6. Disconnect the branch FortiAP and delete it from the Managed FortiAP list.
7. Repeat the preceding steps for each branch FortiAP.

Authorizing leaf APs

When the root FortiAP is connected and online, apply power to the pre-configured leaf FortiAPs. The leaf FortiAPs will connect themselves wirelessly to the WiFi Controller through the mesh network. You must authorize each unit.

1. Go to **WiFi & Switch Controller > Managed FortiAPs**. Periodically select **Refresh** until the FortiAP unit is listed. This can take up to three minutes.

The **State** of the FortiAP unit should be **Waiting for Authorization**.

2. Right-click the FortiAP entry and choose your profile from the **Assign Profile** submenu.

3. Right-click the FortiAP entry and select **Authorize**.

Initially, the **State** of the FortiAP unit is **Offline**. Periodically click **Refresh** to update the status. Within about two minutes, the state changes to **Online**.

Creating security policies

You need to create security policies to permit traffic to flow from the end-user WiFi network to the network interfaces for the Internet and other networks. Enable NAT.

Viewing the status of the mesh network

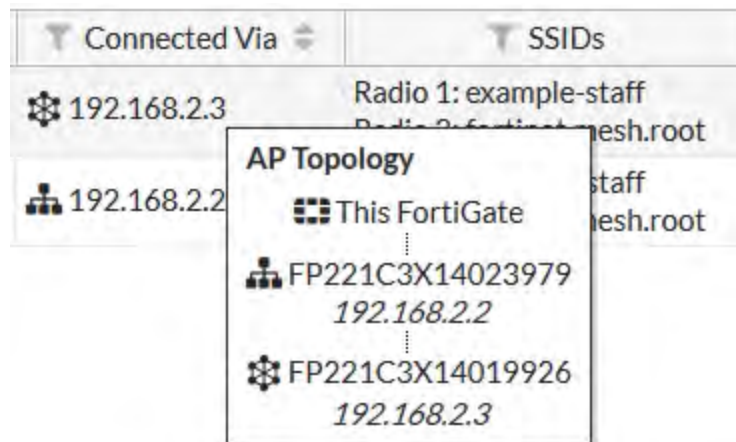

Go to **WiFi & Switch Controller > Managed FortiAPs** to view the list of APs.

+ Create New	Edit	Delete	Refresh	AP	Radio	Managed FortiAPs	2/32
Access Point	State	Connected Via	SSIDs	Channel	Clients	FortiAP Profile	
FP221C3X14019926	✓	192.168.2.3	Radio 1: example-staff Radio 2: fortinet.mesh.root	Radio1: 1 Radio2: 116	Radio 1: 0 Radio 2: 0	mesh-profile	
FP221C3X14023979	✓	192.168.2.2	Radio 1: example-staff Radio 2: fortinet.mesh.root	Radio1: 1 Radio2: 116	Radio 1: 0 Radio 2: 1	mesh-profile	

The **Connected Via** field lists the IP address of each FortiAP and uses icons to show whether the FortiAP is connected by Ethernet or Mesh.

Ethernet	
Mesh	

If you mouse over the Connected Via information, a topology displays, showing how the FortiGate wireless controller connects to the FortiAP.

Configuring a point-to-point bridge

You can create a point-to-point bridge to connect two wired network segments using a WiFi link. The effect is the same as connecting the two network segments to the same wired switch.

You need to:

- Configure a backhaul link and root mesh AP as described in [Configuring a point-to-point bridge on page 1464](#).
Note: The root mesh AP for a point-to-point bridge must be a FortiAP unit, not the internal AP of a FortiWiFi unit.
- Configure bridging on the leaf AP unit.

To configure the leaf AP unit for bridged operation - FortiAP web-based manager

1. With your browser, connect to the FortiAP unit web-based manager.
You can temporarily connect to the unit's Ethernet port and use its default address: 192.168.1.2.
2. Enter:

Operation Mode	Mesh
Mesh AP SSID	fortinet-ap
Mesh AP Password	fortinet
Ethernet Bridge	Select

3. Select **Apply**.
4. Connect the local wired network to the Ethernet port on the FortiAP unit.
Users are assigned IP addresses from the DHCP server on the wired network connected to the root mesh AP unit.

To configure a FortiAP unit as a leaf AP - FortiAP CLI

```
cfg -a MESH_AP_SSID=fortinet-ap
cfg -a MESH_AP_PASSWD=fortinet
cfg -a MESH_ETH_BRIDGE=1
cfg -a MESH_AP_TYPE=1
cfg -c
```

Hotspot 2.0

Hotspot 2.0 Access Network Query Protocol (ANQP) is a query and response protocol that defines seamless roaming services offered by an AP. The following CLI commands are available under `config wireless-controller`, to configure Hotspot 2.0 ANQP.

Syntax

```
config wireless-controller hotspot20 anqp-3gpp-cellular
  edit {name}
    config mcc-mnc-list
      edit {id}
        set id {integer}
        set mcc {string}
        set mnc {string}
      next
    next
  end

config wireless-controller hotspot20 anqp-ip-address-type
  edit {name}
    set ipv6-address-type {option}
    set ipv4-address-type {option}
  next
end

config wireless-controller hotspot20 anqp-nai-realm
```

```
edit {name}
  config nai-list
  edit {name}
    set encoding {enable | disable}
    set nai-realm {string}
    config eap-method
    edit {index}
      set index {integer}
      set method {option}
      config auth-param
      edit {index}
        set index {integer}
        set id {option}
        set val {option}
      next
    next
  next
end

config wireless-controller hotspot20 anqp-network-auth-type
edit {name}
  set auth-type {option}
  set url {string}
next
end

Combining WiFi and wired networks with a software switch

Combining WiFi and wired networks with a software switch

A WiFi network can be combined with a wired LAN so that WiFi and wired clients are on the same subnet. This is a convenient configuration for users. Note that software switches are only available if your FortiGate is in Interface mode.

Wireless Mesh features cannot be used in conjunction with this configuration because they enable the FortiAP Local Bridge option.

To create the WiFi and wired LAN configuration, you need to:

- Configure the SSID so that traffic is tunneled to the WiFi controller.
- Configure a software switch interface on the FortiGate unit with the WiFi and internal network interface as members.
- Configure Captive Portal security for the software switch interface.

To configure the SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New**.
2. Enter:

Interface name	A name for the new WiFi interface, <code>homenet_if</code> for example.
Traffic Mode	Tunnel to Wireless Controller
SSID	The SSID visible to users, <code>homenet</code> for example.
Security Mode Data Encryption Preshared Key	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi & Switch Controller > Managed FortiAPs**, select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

To configure the SSID - CLI

This example creates a WiFi interface “homenet_if” with SSID “homenet” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "homenet_if"
    set vdom "root"
    set ssid "homenet"
```

```
        set security wpa-personal
        set passphrase "Fortinet1"
    end
    config wireless-controller wtp
        edit FAP22B3U11005354
            set admin enable
            set vaps "homenet_if"
        end
    end
```

To configure the FortiGate software switch - web-based manager

1. Go to **Network > Interfaces** and select **Create New > Interface**.
2. Enter:

Interface Name	A name for the new interface, <code>homenet_nw</code> for example.
Type	Software Switch
Physical Interface Members	Add <code>homenet_if</code> and the internal network interface.
Addressing mode	Select Manual and enter an address, for example <code>172.16.96.32/255.255.255.0</code>
DHCP Server	Enable and configure an address range for clients.
Security Mode	Select Captive Portal . Add the permitted User Groups .

3. Select **OK**.

To configure the FortiGate unit - CLI

```
config system interface
    edit homenet_nw
        set ip 172.16.96.32 255.255.255.0
        set type switch
        set security-mode captive-portal
        set security-groups "Guest-group"
    end
config system interface
    edit homenet_nw
        set member "homenet_if" "internal"
    end
```

VLAN configuration

If your environment uses VLAN tagging, you assign the SSID to a specific VLAN in the CLI. For example, to assign the `homenet_if` interface to VLAN 100, enter:

```
config wireless-controller vap
    edit "homenet_if"
        set vlanid 100
    end
```

Additional configuration

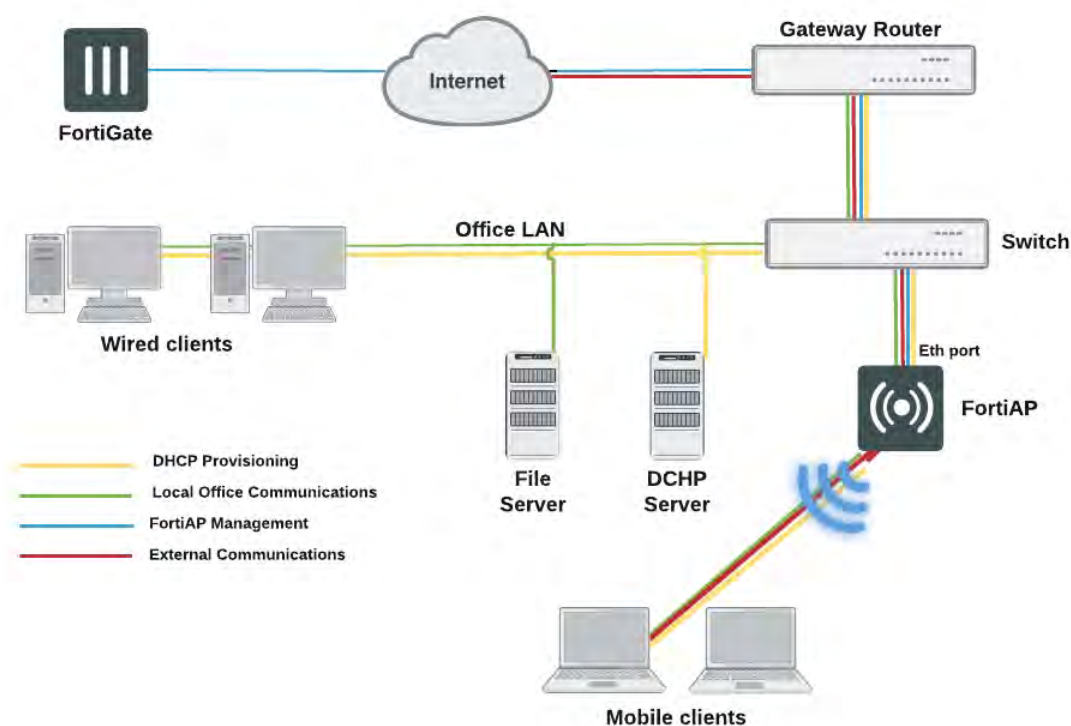

The configuration described above provides communication between WiFi and wired LAN users only. To provide access to other networks, create appropriate firewall policies between the software switch and other interfaces.

FortiAP local bridging (Private Cloud-Managed AP)

A FortiAP unit can provide WiFi access to a LAN, even when the wireless controller is located remotely. This configuration is useful for the following situations:

- Installations where the WiFi controller is remote and most of the traffic is local or uses the local Internet gateway
- Wireless-PCI compliance with remote WiFi controller
- Telecommuting, where the FortiAP unit has the WiFi controller IP address pre-configured and broadcasts the office SSID in the user's home or hotel room. In this case, data is sent in the wireless tunnel across the Internet to the office and you should enable encryption using DTLS.

Remotely-managed FortiAP providing WiFi access to local network

On the remote FortiGate wireless controller, the WiFi SSID is created with the **Bridge with FortiAP Interface** option selected. In this mode, no IP addresses are configured. The FortiAP unit's WiFi and Ethernet interfaces behave as a switch. WiFi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN.

The Local Bridge feature cannot be used in conjunction with Wireless Mesh features.

Block-Intra-SSID Traffic is available in Bridge mode. This is useful in hotspot deployments managed by a central FortiGate, but would also be useful in cloud deployments. Previously, this was only supported in Tunnel mode.

To configure a FortiAP local bridge - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter:

Interface name	A name for the new WiFi interface.
Traffic Mode	Local bridge with FortiAP's Interface
SSID	The SSID visible to users.
Security Mode Data Encryption Preshared Key	Configure security as you would for a regular WiFi network.

3. Select **OK**.
4. Go to **WiFi & Switch Controller > Managed FortiAPs** and select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

SSID configured for Local Bridge operation

New Interface

Interface Name:

Type:

Traffic Mode:

WiFi Settings

SSID:

Security Mode:

Pre-shared Key: (8 - 63 characters)

Allow New WiFi Client Connections When Controller Is Down: ☐

Schedule:

Maximum Clients:

Optional VLAN ID:

To configure a FortiAP local bridge - CLI

This example creates a WiFi interface “branchbridge” with SSID “LANbridge” using WPA-Personal security, passphrase “Fortinet1”.

```

config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "branchbridge"
  end

```

Note that:

- Disabling local-bridging forcefully disables local-standalone. Also, disabling either local-bridging or local-standalone forcefully disables intra-vap-privacy.
- Enabling intra-vap-privacy forcefully disables local-standalone.
- Enabling local-standalone forcefully enables local-bridging also.

Continued FortiAP operation when WiFi controller connection is down

The wireless controller, or the connection to it, might occasionally become unavailable. During such an outage, clients already associated with a bridge mode FortiAP unit continue to have access to the WiFi and wired networks. Optionally, the FortiAP unit can also continue to authenticate users if the SSID meets these conditions:

- **Traffic Mode is Local bridge with FortiAP's Interface.**
In this mode, the FortiAP unit does not send traffic back to the wireless controller.
- **Security Mode is WPA2 Personal.**
These modes do not require the user database. In WPA2 Personal authentication, all clients use the same pre-shared key which is known to the FortiAP unit.
- **Allow New WiFi Client Connections When Controller is down** is enabled.
This field is available only if the other conditions have been met.

The "LANbridge" SSID example would be configured like this in the CLI:

```

config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
    set local-authentication enable
  end

```

Using bridged FortiAPs to increase scalability

The FortiGate wireless controller can support more FortiAP units in local bridge mode than in the normal mode. But this is only true if you configure some of your FortiAP units to operate in remote mode, which supports only local bridge mode SSIDs.

The Managed FortiAP page (**WiFi & Switch Controller > Managed FortiAPs**) shows at the top right the current number of Managed FortiAPs and the maximum number that can be managed, “5/64” for example. The maximum number, however, is true only if all FortiAP units operate in remote mode. For more detailed information, consult the Maximum Values Table. For each FortiGate model, there are two maximum values for managed FortiAP units: the total number of FortiAPs and the number of FortiAPs that can operate in normal mode.

To configure FortiAP units for remote mode operation

1. Create at least one SSID with **Traffic Mode** set to **Local bridge with FortiAP's Interface**.
2. Create a custom AP profile that includes *only* local bridge SSIDs.
3. Configure each managed FortiAP unit to use the custom AP profile. You also need to set the FortiAP unit's `wtp-mode` to `remote`, which is possible only in the CLI. The following example uses the CLI both to set `wtp-mode` and select the custom AP profile:

```
config wireless-controller wtp
  edit FAP22B3U11005354
    set wtp-mode remote
    set wtp-profile 220B_bridge
  end
```

Using Remote WLAN FortiAPs

Remote WLAN FortiAP models enable you to provide a pre-configured WiFi access point to a remote or traveling employee. Once plugged in at home or in a hotel room, the FortiAP automatically discovers the enterprise FortiGate WiFi controller over the Internet and broadcasts the same wireless SSID used in the corporate office. Communication between the WiFi controller and the FortiAP is secure, eliminating the need for a VPN.

Split tunneling

By default, all traffic from the remote FortiAP is sent to the FortiGate WiFi controller. If split tunneling is configured, only traffic destined for the corporate office networks is routed to the FortiGate unit. Other general Internet traffic is routed unencrypted through the local gateway. Split tunneling avoids loading the FortiGate unit with unnecessary traffic and allows direct access to local private networks at the FortiAP's location even if the connection to the WiFi controller goes down.

Note: Split tunneling in WiFi networks differs in implementation from split tunneling in VPN configurations.

By default, split tunneling options are not visible in the FortiGate GUI. You can make these options visible using the following CLI command:

```
config system settings
    set gui-fortiap-split-tunneling enable
end
```

Split tunneling is configured in **Managed FortiAPs**, **FortiAP Profiles**, and enabled in the **SSID**.

Configuring the FortiGate for remote FortiAPs

This section assumes that you have already defined SSIDs and now want to make them available to remote FortiAPs.

- Create FortiAP profiles for the Remote LAN FortiAP models
- If split tunneling will be used
 - configure override split tunneling in Managed FortiAPs
 - enable Split Tunneling in the SSID
 - configure the split tunnel networks in the FortiAP profile

Override Split Tunneling

Go to **WiFi & Switch Controller > Managed FortiAPs** and edit your managed APs. When preconfiguring the AP to connect to your FortiGate WiFi controller, you can choose to override split tunneling, optionally including the local subnet of the FortiAP.

Creating FortiAP profiles

If you were not already using Remote LAN FortiAP models, you will need to create FortiAP profiles for them. In the FortiAP profile, you specify the SSIDs that the FortiAP will broadcast. For more information, see ["Creating a FortiAP Profile" on page 1417](#).

Configuring split tunneling - FortiGate GUI

Go to **WiFi & Switch Controller > SSID** and edit your SSID. In the **WiFi Settings** section, enable **Split Tunneling**.

Go to **WiFi Controller > FortiAP Profiles** and edit the FortiAP Profile(s) that apply to the AP types used in the WiFi network. In the **Split Tunneling** section, enable **Include Local Subnet** and **Split Tunneling Subnet(s)**, where you can enter a list all of the destination IP address ranges that should **not** be routed through the the FortiGate WiFi controller. Packets for these destinations will instead be routed through the remote gateway local to the FortiAP.

The list of split tunneling subnets includes public Internet destinations and private subnets local to the FortiAP. Split tunneling public Internet destinations reduces traffic through the FortiGate unit. Split tunneling local private subnets allows these networks to be accessible to the client behind the FortiAP. Otherwise, private network IP destinations are assumed to be behind the FortiGate WiFi controller.

Configuring split tunneling - FortiGate CLI

In this example, split tunneling is configured on the example-ssid WiFi network. On FortiAP model 21D, traffic destined for the 192.168.x.x range will not be routed through the FortiGate WiFi controller. This private IP address range is typically used as a LAN by home routers.

```
config wireless-controller vap
  edit example-ssid
    set split-tunneling enable
  end

config wireless-controller wtp-profile
  edit FAP21D-default
    set split-tunneling-acl-local-ap-subnet enable
    config split-tunneling-acl
      edit 1
        set dest-ip 192.168.0.0 255.255.0.0
      end
    end
  end
```

To enter multiple subnets, create a split-tunneling-acl entry for each one.

Overriding the split tunneling settings on a FortiAP

If the FortiAP Profile split tunneling settings are not appropriate for a particular FortiAP, you can override the settings on that unit.

```
config wireless-controller wtp
  edit FAP321C3X14019926
    set override-split-tunnel enable
    set split-tunneling-acl-local-ap-subnet enable
    config split-tunneling-acl
      edit 1
        set dest-ip 192.168.10.0 255.255.255.0
      end
    end
  end
```

Configuring the FortiAP units

Prior to providing a Remote WLAN FortiAP unit to an employee, you need to preconfigure the AP to connect to your FortiGate WiFi controller.

To pre-configure a FortiAP

1. Connect the FortiAP to the FortiGate unit.
2. Go to **WiFi & Switch Controller > Managed FortiAPs** and wait for the FortiAP to be listed. Click **Refresh** periodically to see the latest information. Note the **Connected Via** IP address.
3. Go to **Dashboard**. In the CLI Console, log into the FortiAP CLI.
For example, if the IP address is 192.168.1.4, enter:

```
exec telnet 192.168.1.4
```

Enter *admin* at the login prompt. By default, no password is set.
4. Enter the following commands to set the FortiGate WiFi controller IP address. This should be the FortiGate Internet-facing IP address, in this example 172.20.120.142.

```
cfg -a AC_IPADDR_1=172.20.120.142
cfg -c
```
5. Enter *exit* to log out of the FortiAP CLI.

Preauthorizing FortiAP units

By preauthorizing FortiAP units, you facilitate their automatic authorization on the network. Also, you can assign each unit a unique name, such as the employee's name, for easier tracking.

1. Go to **WiFi & Switch Controller > Managed FortiAPs** and create a new entry.
2. Enter the **Serial Number** of the FortiAP unit and give it a **Name**. Select the appropriate **FortiAP Profile**.
3. Click **OK**.

Repeat this process for each FortiAP.

Features for high-density deployments

High-density environments such as auditoriums, classrooms, and meeting rooms present a challenge to WiFi providers. When a large number of mobile devices try to connect to a WiFi network, difficulties arise because of the limited number of radio channels and interference between devices.

FortiOS and FortiAP devices provide several tools to mitigate the difficulties of high-density environments.

Power save feature

Occasionally, voice calls can become disrupted. One way to alleviate this issue is by controlling the power save feature, or to disable it altogether.

Manually configure packet transmit optimization settings by entering the following command:

```
config wireless-controller wtp-profile
edit <name>
    config <radio-1> | <radio-2>
        set transmit-optimize {disable | power-save | aggr-limit | retry-limit | sendbar}
```

- **disable:** Disable transmit optimization.
- **power-save:** Mark a client as power save mode if excessive transmit retries happen.
- **aggr-limit:** Set aggregation limit to a lower value when data rate is low.
- **retry-limit:** Set software retry limit to a lower value when data rate is low.
- **send-bar:** Do not send BAR frame too often.

11n radio powersave optimization

The following `powersave-optimize` parameters (under `config radio`) are used for 11n radios to optimize system performance for specific situations.

- **tim:** Set traffic indication map (TIM) bit for client in power save mode. TIM bit mask indicates to any sleeping listening stations if the AP has any buffered frames present. If enabled, the AP will always indicate to the connected client that there is a packet waiting in the AP, so it will help to prevent the client from entering a sleep state.
- **ac-vo:** Use Access Category (AC) Voice (VO) priority to send packets in the power save queue. AC VO is one of the highest classes/priority levels used to ensure quality of service (QoS). If enabled, when a client returns from a sleep state, the AP will send its buffered packet using a higher priority queue, instead of the normal priority queue.
- **no-obss-scan:** Do not put Overlapping Basic Service Set (OBSS), or high-noise (i.e. non-802.11), scan IE into a Beacon or Probe Response frame.
- **no-11b-rate:** Do not send frame using 11b data rate.
- **client-rate-follow:** Adapt transmitting PHY rate with receiving PHY rate from client. If enabled, the AP will integrate the current client's transmission PHY rate into its rate adaptation algorithm for transmitting.

Broadcast packet suppression

Broadcast packets are sent at a low data rate in WiFi networks, consuming valuable air time. Some broadcast packets are unnecessary or even potentially detrimental to the network and should be suppressed.

ARP requests and replies could allow clients to discover each other's IP addresses. On most WiFi networks, intra-client communication is not allowed, so these ARP requests are of no use, but they occupy air time.

DHCP (upstream) should be allowed so that clients can request an IP address using DHCP.

DHCP (downstream) should be suppressed because it would allow a client to provide DHCP service to other clients. Only the AP should do this.

NetBIOS is a Microsoft Windows protocol for intra-application communication. Usually this is not required in high-density deployments.

IPv6 broadcast packets can be suppressed if your network uses IPv4 addressing.

You can configure broadcast packet suppression in the CLI. The following options are available for broadcast suppression:

```
config wireless-controller vap
  edit <name>
    set broadcast-suppression {dhcp-up | dhcp-down | dhcp-starvation | arp-known | arp-unknown | arp-reply | arp-poison | arp-proxy | netbios-ns | netbios-ds | ipv6 | all-other-mc | all-other-bc}
  end
```

`dhcp-starvation` helps prevent clients from depleting the DHCP address pool by making multiple requests.

`arp-poison` helps prevent clients from spoofing ARP messages.

Because of all these specific multicast and broadcast packet types, the two options `all-other-mc` and `all-other-bc` help suppress multicast (`mc`) and broadcast (`bc`) packets that are not covered by any of the specific options.

Multicast to unicast conversion

Multicast data such as streaming audio or video are sent at a low data rate in WiFi networks. This causes them to occupy considerable air time. FortiOS provides a multicast enhancement option that converts multicast streams to unicast. A unicast stream is sent to each client at high data rate that makes more efficient use of air time. You can configure multicast-to-unicast conversion in the CLI:

```
config wireless-controller vap
  edit <vap_name>
    set multicast-enhance enable
  end
```

Ignore weak or distant clients

Clients beyond the intended coverage area can have some impact on your high-density network. Your APs will respond to these clients' probe signals, consuming valuable air time. You can configure your WiFi network to ignore weak signals that most likely come from beyond the intended coverage area. The settings are available in the CLI:

```
config wireless-controller vap
  edit <vap_name>
    set probe-resp-suppression enable
    set probe-resp-threshold <level_int>
  end
```

vap_name is the SSID name.

probe-resp-threshold is the signal strength in dBm below which the client is ignored. The range is -95 to -20dBm. The default level is -80dBm.

Turn off 802.11b protocol

By disabling support for the obsolete 802.11b protocol, you can reduce the air time that data frames occupy. These signals will now be sent at a minimum of 6Mbps, instead of 1Mbps. You can set this for each radio in the FortiAP profile, using the CLI:

```
config wireless-controller wtp-profile
  edit <name_string>
    config radio-1
      set powersave-optimize no-11b-rate
    end
```

Disable low data rates

Each of the 802.11 protocols supports several data rates. By disabling the lowest rates, air time is conserved, allowing the channel to serve more users. You can set the available rates for each 802.11 protocol: a, b, g, n, ac. Data rates set as Basic are mandatory for clients to support. Other specified rates are supported.

The 802.11 a, b, and g protocols are specified by data rate. 802.11a can support 6,9,12, 18, 24, 36, 48, and 54 Mb/s. 802.11b/g can support 1, 2, 5.5, 6, 9,12, 18, 24, 36, 48, 54 Mb/s. Basic rates are specified with the suffix "basic", "12-basic" for example. The capabilities of expected client devices need to be considered when deciding the lowest Basic rate.

The 802.11n and ac protocols are specified by the Modulation and Coding Scheme (MCS) Index and the number of spatial streams.

- 802.11n with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1, mcs8/2, mcs9/2, mcs10/2, mcs11/2, mcs12/2, mcs13/2, mcs14/2, mcs15/2.
- 802.11n with 3 or 4 spatial streams can support mcs16/3, mcs17/3, mcs18/3, mcs19/3, mcs20/3, mcs21/3, mcs22/3, mcs23/3, mcs24/4, mcs25/4, mcs26/4, mcs27/4, mcs28/4, mcs29/4, mcs30/4, mcs31/4.
- 802.11ac with 1 or 2 spatial streams can support mcs0/1, mcs1/1, mcs2/1, mcs3/1, mcs4/1, mcs5/1, mcs6/1, mcs7/1, mcs8/1, mcs9/1, mcs0/2, mcs1/2, mcs2/2, mcs3/2, mcs4/2, mcs5/2, mcs6/2, mcs7/2, mcs8/2, mcs9/2.
- 802.11ac with 3 or 4 spatial streams can support mcs0/3, mcs1/3, mcs2/3, mcs3/3, mcs4/3, mcs5/3, mcs6/3, mcs7/3, mcs8/3, mcs9/3, mcs0/4, mcs1/4, mcs2/4, mcs3/4, mcs4/4, mcs5/4, mcs6/4, mcs7/4, mcs8/4, mcs9/4

Here are some examples of setting basic and supported rates.

```
config wireless-controller vap
  edit <vap_name>
    set rates-11a 12-basic 18 24 36 48 54
    set rates-11bg 12-basic 18 24 36 48 54
    set rates-11n-ss34 mcs16/3 mcs18/3 mcs20/3 mcs21/3 mcs22/3 mcs23/3 mcs24/4 mcs25/4
    set rates-11ac-ss34 mcs0/3 mcs1/3 mcs2/3 mcs9/4 mcs9/3
  end
```

Limit power

High-density deployments usually cover a small area that has many clients. Maximum AP signal power is usually not required. Reducing the power reduces interference between APs. Fortinet recommends that you use FortiAP automatic power control. You can set this in the FortiAP profile.

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile for your AP model.
2. For each radio, enable **Auto TX Power Control** and set the **TX Power Low** and **TX Power High** levels. The default range of 10 to 17dBm is recommended.

Use frequency band load-balancing

In a high-density environment is important to make the best use of the two WiFi bands, 2.4GHz and 5GHz. The 5GHz band has more non-overlapping channels and receives less interference from non-WiFi devices, but not all devices support it. Clients that are capable of 5GHz operation should be encouraged to use 5GHz rather than the 2.4GHz band.

To load-balance the WiFi bands, you enable Frequency Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi & Switch Controller > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
  edit FAP221C-default
    config radio-1
      set frequency-handoff enable
    end
```

The FortiGate wireless controller continuously performs a scan of all clients in the area and records their signal strength (RSSI) on each band. When Frequency Handoff is enabled, the AP does not reply to clients on the 2.4GHz band that have sufficient signal strength on the 5GHz band. These clients can associate only on the 5GHz band. Devices that support only 2.4GHz receive replies and associate with the AP on the 2.4GHz band.

Setting the handoff RSSI threshold

The FortiAP applies load balancing to a client only if the client has a sufficient signal level on 5GHz. The minimum signal strength threshold is set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
  edit FAP221C-default
    set handoff-rssi 25
  end
```

`handoff-rssi` has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

AP load balancing

The performance of an AP is degraded if it attempts to serve too many clients. In high-density environments, multiple access points are deployed with some overlap in their coverage areas. The WiFi controller can manage the association of new clients with APs to prevent overloading.

To load-balance between APs, enable AP Handoff in the FortiAP profile. In the FortiGate web-based manager, go to **WiFi & Switch Controller > FortiAP Profiles** and edit the relevant profile. Or, you can use the CLI:

```
config wireless-controller wtp-profile
  edit FAP221C-default
    config radio-1
      set ap-handoff enable
    end
```

When an AP exceeds the threshold (the default is 30 clients), the overloaded AP does not reply to a new client that has a sufficient signal at another AP.

Setting the AP load balance threshold

The thresholds for AP handoff are set in the FortiAP profile, but is accessible only through the CLI:

```
config wireless-controller wtp-profile
edit FAP221C-default
    set handoff-sta-thresh 30
    set handoff-rssi 25
end
```

`handoff-sta-thresh` sets the number of clients at which AP load balancing begins. It has a range of 5 to 35.

`handoff-rssi` Sets the minimum signal strength that a new client must have at an alternate AP for the overloaded AP to ignore the client. It has a range of 20 to 30. RSSI is a relative measure. The higher the number, the stronger the signal.

Application rate-limiting

To prevent particular application types from consuming too much bandwidth, you can use the FortiOS Application Control feature.

1. Go to **Security Profiles > Application Control**.
You can use the default profile or create a new one.
2. Click the category, select **Traffic Shaping** and then select the priority for the category.
Repeat for each category to be controlled.
3. Select **Apply**.
4. Go to **Policy & Objects > IPv4 Policy** and edit your WiFi security policy.
5. In **Security Profiles**, set **Application Control** ON and select the security profile that you edited.
6. Select **OK**.

AP Group management and dynamic VLAN assignment

The FortiGate can create FortiAP Groups, under **WiFi & Switch Controller > Managed Devices > Managed FortiAPs** by selecting **Create New > Managed AP Group**, where multiple APs can be managed. AP grouping allows specific profile settings to be applied to many APs all at once that belong to a certain AP group, simplifying the administrative workload.

Note that each AP can only belong to one group.

In addition, VLANs can be assigned dynamically based on the group which an AP belongs. When defining an SSID, under **WiFi & Switch Controller > SSID**, a setting called **VLAN Pooling** can be enabled where you can either assign the VLAN ID of the AP group the device is connected to, to each device as it is detected, or to always assign the same VLAN ID to a specific device. Dynamic VLAN assignment allows the same SSID to be deployed to many APs, avoiding the need to produce multiple SSIDs.

Sharing Tunnel SSIDs within a single managed AP between VDOMs as a Virtual AP for multi-tenancy

This feature provides the ability to move a tunnel mode VAP into a VDOM, similar to an interface/VLAN in VDOMs. FortiAP is registered into the root VDOM.

Within a customer VDOM, customer VAPs can be created/added. In the root VDOM, the customer VAP can be added to the registered FortiAP. Any necessary firewall rules and interfaces can be configured between the two VDOMs.

Syntax

```
config wireless-controller global
  set wtp-share {enable | disable}
end
```

FortiAP LED Blinking

This feature allows the administrator to select a FortiAP from the FortiCloud WebUI and set its LED status to blink in order to help the administrator find that FortiAP in an environment consisting of many APs.

FortiAP-112D, 221C, 223C, 224D, 320C, and 321C (using v5.6.2 B0489) can support LED Blinking.

Syntax

```
execute wireless-controller led-blink <wtp-id> {on | on 10 | off}
```

Wireless controller optimization for large deployment - AP image upgrade

This feature allows the administrator to configure a FortiAP to download the WTP image at join time.

Syntax

```
config wireless-controller global
  set image-download {enable | disable}
end
```

Protecting the WiFi Network

Wireless IDS

The FortiGate Wireless Intrusion Detection System (WIDS) monitors wireless traffic for a wide range of security threats by detecting and reporting on possible intrusion attempts. When an attack is detected the FortiGate unit records a log message.

You can create a WIDS profile to enable these types of intrusion detection:

- **Asleep Attack**—ASLEAP is a tool used to perform attacks against LEAP authentication.
- **Association Frame Flooding**—A Denial of Service attack using a large number of association requests. The default detection threshold is 30 requests in 10 seconds.
- **Authentication Frame Flooding**—A Denial of Service attack using a large number of association requests. The default detection threshold is 30 requests in 10 seconds.
- **Broadcasting De-authentication**—This is a type of Denial of Service attack. A flood of spoofed de-authentication frames forces wireless clients to de-authenticate, then re-authenticate with their AP.
- **EAPOL Packet Flooding**—Extensible Authentication Protocol over LAN (EAPOL) packets are used in WPA and WPA2 authentication. Flooding the AP with these packets can be a denial of service attack. Several types of EAPOL packets are detected: EAPOL-FAIL, EAPOL-LOGOFF, EAPOL-START, EAPOL-SUCC.
- **Invalid MAC OUI**—Some attackers use randomly-generated MAC addresses. The first three bytes of the MAC address are the Organizationally Unique Identifier (OUI), administered by IEEE. Invalid OUIs are logged.
- **Long Duration Attack**—To share radio bandwidth, WiFi devices reserve channels for brief periods of time. Excessively long reservation periods can be used as a denial of service attack. You can set a threshold between 1000 and 32 767 microseconds. The default is 8200.
- **Null SSID Probe Response**—When a wireless client sends out a probe request, the attacker sends a response with a null SSID. This causes many wireless cards and devices to stop responding.
- **Spoofed De-authentication**—Spoofed de-authentication frames are a denial of service attack. They cause all clients to disconnect from the AP.
- **Weak WEP IV Detection**—A primary means of cracking WEP keys is by capturing 802.11 frames over an extended period of time and searching for patterns of WEP initialization vectors (IVs) that are known to be weak. WIDS detects known weak WEP IVs in on-air traffic.
- **Wireless Bridge**—WiFi frames with both the fromDS and ToDS fields set indicate a wireless bridge. This will also detect a wireless bridge that you intentionally configured in your network.

You can enable wireless IDS by selecting a WIDS Profile in your FortiAP profile.

To create a WIDS Profile

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
2. Select a profile to edit or select **Create New**.
3. Select the types of intrusion to protect against.
By default, all types are selected.
4. Select **Apply**.

You can also configure a WIDS profile in the CLI using the `config wireless-controller wids-profile` command.

Rogue AP detection

The WIDS profile includes settings for detection of unauthorized (rogue) access points in your wireless network. For more information, see [Wireless network monitoring on page 1489](#).

WIDS client deauthentication rate for DoS attacks

As part of mitigating a Denial of Service (DoS) attack, the FortiGate sends deauthentication packets to unknown clients. In an aggressive attack, this deauthentication activity can prevent the processing of packets from valid clients. A WIDS Profile option in the CLI limits the deauthentication rate.

```
config wireless-controller wids-profile
  edit default
    set deauth-unknown-src-thresh <1-65535>
  end
```

The value set is a measure of the number of deauthorizations per second. 0 means no limit. The default is 10.

WiFi data channel encryption

Optionally, you can apply DTLS encryption to the data channel between the wireless controller and FortiAP units. This enhances security.

There are data channel encryption settings on both the FortiGate unit and the FortiAP units. At both ends, you can enable Clear Text, DTLS encryption, or both. The settings must agree or the FortiAP unit will not be able to join the WiFi network. By default, both Clear Text and DTLS-encrypted communication are enabled on the FortiAP unit, allowing the FortiGate setting to determine whether data channel encryption is used. If the FortiGate unit also enables both Clear Text and DTLS, Clear Text is used.

Data channel encryption settings are located in the FortiAP profile. By default, only Clear Text is supported.

Data channel encryption is software-based and can affect performance. Verify that the system meets your performance requirements with encryption enabled.

Configuring encryption on the FortiGate unit

You can use the CLI to configure data channel encryption.

Enabling encryption

In the CLI, the `wireless wtp-profile` command contains a new field, `dtls-policy`, with options `clear-text` and `dtls-enabled`. To enable encryption in profile1 for example, enter:

```
config wireless-controller wtp-profile
  edit profile1
    set dtls-policy dtls-enabled
  end
```

Configuring encryption on the FortiAP unit

The FortiAP unit has its own settings for data channel encryption.

Enabling CAPWAP encryption - FortiAP web-based manager

1. On the **System Information** page, in **WTP Configuration > AC Data Channel Security**, select one of:
 - Clear Text
 - DTLS Enabled
 - Clear Text or DTLS Enabled (default)
2. Select **Apply**.

Enabling encryption - FortiAP CLI

You can set the data channel encryption using the `AP_DATA_CHAN_SEC` variable: 'clear', or 'ipsec', or 'dtls'.

For example, to set security to DTLS and then save the setting, enter:

```
cfg -a AP_DATA_CHAN_SEC=dtls
cfg -c
```

Protected Management Frames and Opportunistic Key Caching support

Protected Management Frames (PMF) protect some types of management frames like deauthorization, disassociation and action frames. This feature, now mandatory on WiFi certified 802.11ac devices, prevents attackers from sending plain deauthorization/disassociation frames to disrupt or tear down a connection/association. PMF is a Wi-Fi Alliance specification based on IEEE 802.11w.

To facilitate faster roaming client roaming, you can enable Opportunistic Key Caching (OKC) on your WiFi network. When a client associates with an AP, its PMK identifier is sent to all other APs on the network. This eliminates the need for an already-authenticated client to repeat the full EAP exchange process when it roams to another AP on the same network.

Use of PMF and OKC on an SSID is configurable only in the CLI:

```
config wireless-controller vap
  edit <vap_name>
    set pmf {disable | enable | optional}
    set pmf-assoc-comeback-timeout <integer>
    set pmf-sa-query-retry-timeout <integer>
    set okc {disable | enable}
  next
end
```

When `pmf` is set to `optional`, it is considered enabled, but will allow clients that do not use PMF. When `pmf` is set to `enable`, PMF is required by all clients.

Bluetooth Low Energy (BLE) Scan

The FortiGate can configure FortiAP Bluetooth Low Energy (BLE) scan, incorporating Google's BLE beacon profile known as Eddystone, used to identify groups of devices and individual devices.

Currently, only the FAP-S221E, FAP-S223E, and FAP-222E models support this feature.

Use the following syntax to configure BLE profiles, configure BLE report intervals, and assign BLE profiles to WTP profiles.

CLI syntax - Configure BLE profiles

```
config wireless-controller ble-profile
edit <name>
    set comment <comment>
    set advertising {ibeacon | eddystone-uid | eddystone-url}
    set ibeacon-uuid <uuid>
    set major-id <0 - 65535> - (default = 1000)
    set minor-id <0 - 65535> - (default = 1000)
    set eddystone-namespace <10-byte namespace>
    set eddystone-instance <device id>
    set eddystone-url <url>
    set txpower <0 - 12> - (default = 0)
    set beacon-interval <40 - 3500> - (default = 100)
    set ble-scanning {enable | disable} - (default = disable)
next
end
```

Note that `txpower` determines the transmit power level on a scale of 0-12:

0: -21 dBm	1: -18 dBm	2: -15 dBm	3: -12 dBm	4: -9 dBm
5: -6 dBm	6: -3 dBm	7: 0 dBm	8: 1 dBm	9: 2 dBm
10: 3 dBm	11: 4 dBm	12: 5 dBm		

CLI syntax - Configure BLE report intervals

```
config wireless-controller timers
    set ble-scan-report-intv - (default = 30 sec)
end
```

CLI syntax - Assign BLE profiles to WTP profiles

```
config wireless-controller wtp-profile
edit <name>
    set ble-profile <name>
next
end
```

Wireless network monitoring

You can monitor both your wireless clients and other wireless networks that are available in your coverage area.

Monitoring wireless clients

To view connected clients on a FortiWiFi unit

1. Go to **Monitor > Client Monitor**.
The following information is displayed:

SSID	The SSID that the client connected to.
FortiAP	The serial number of the FortiAP unit to which the client connected.
User	User name
IP	The IP address assigned to the wireless client.
Device	
Auth	The type of authentication used.
Channel	WiFi radio channel in use.
Bandwidth Tx/Rx	Client received and transmitted bandwidth, in Kbps.
Signal Strength / Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
Signal Strength	
Association Time	How long the client has been connected to this access point.

Results can be filtered. Select the filter icon on the column you want to filter. Enter the values to include or select NOT if you want to exclude the specified values.

Monitoring rogue APs

The access point radio equipment can scan for other available access points, either as a dedicated monitor or in idle periods during AP operation.

Discovered access points are listed in **Monitor > Rogue AP Monitor**. You can then mark them as either Accepted or Rogue access points. This designation helps you to track access points. It does not affect anyone's ability to use these access points.

It is also possible to suppress rogue APs. See [Monitoring rogue APs on page 1489](#).

On-wire rogue AP detection technique

Other APs that are available in the same area as your own APs are not necessarily rogues. A neighboring AP that has no connection to your network might cause interference, but it is not a security threat. A rogue AP is an unauthorized AP connected to your wired network. This can enable unauthorized access. When rogue AP detection is enabled, the **On-wire** column in the **Rogue AP Monitor** list shows a green up-arrow on detected rogues.

Rogue AP monitoring of WiFi client traffic builds a table of WiFi clients and the Access Points that they are communicating through. The FortiGate unit also builds a table of MAC addresses that it sees on the LAN. The FortiGate unit's on-wire correlation engine constantly compares the MAC addresses seen on the LAN to the MAC addresses seen on the WiFi network.

There are two methods of Rogue AP on-wire detection operating simultaneously: Exact MAC address match and MAC adjacency.

Exact MAC address match

If the same MAC address is seen on the LAN and on the WiFi network, this means that the wireless client is connected to the LAN. If the AP that the client is using is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue. This scheme works for non-NAT rogue APs.

MAC adjacency

If an access point is also a router, it applies NAT to WiFi packets. This can make rogue detection more difficult. However, an AP's WiFi interface MAC address is usually in the same range as its wired MAC address. So, the MAC adjacency rogue detection method matches LAN and WiFi network MAC addresses that are within a defined numerical distance of each other. By default, the MAC adjacency value is 7. If the AP for these matching MAC addresses is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue.

Limitations

On-wire rogue detection has some limitations. There must be at least one WiFi client connected to the suspect AP and continuously sending traffic. If the suspect AP is a router, its WiFi MAC address must be very similar to its Ethernet port MAC address.

Logging

Information about detected rogue APs is logged and uploaded to your FortiAnalyzer unit, if you have one. By default, rogue APs generate an alert level log, unknown APs generate a warning level log. This log information can help you with PCI-DSS compliance requirements.

Rogue AP scanning as a background activity

Each WiFi radio can perform monitoring of radio channels in its operating band while acting as an AP. It does this by briefly switching from AP to monitoring mode. By default, a scan period starts every 300 seconds. Each second a different channel is monitored for 20ms until all channels have been checked.

During heavy AP traffic, it is possible for Spectrum Analysis background scanning to cause lost packets when the radio switches to monitoring. To reduce the probability of lost packets, you can set the CLI `ap-bgscan-idle` field to delay the switch to monitoring until the AP has been idle for a specified period. This means that heavy AP traffic may slow background scanning.

The following CLI example configures default background rogue scanning operation except that it sets `ap-bgscan-idle` to require 100ms of AP inactivity before scanning the next channel.

```
config wireless-controller wtp-profile
  edit ourprofile
    config radio-1
      set wids-profile ourwidsprofile
      set spectrum-analysis enable
    end
  end
config wireless-controller wids-profile
  edit ourwidsprofile
    set ap-scan enable
    set rogue-scan enable
    set ap-bgscan-period 300
    set ap-bgscan-intv 1
    set ap-bgscan-duration 20
    set ap-bgscan-idle 100
  end
```

Configuring rogue scanning

All APs using the same FortiAP Profile share the same rogue scanning settings, unless override is configured.

To enable rogue AP scanning with on-wire detection - web-based manager

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
On some models, the menu is **WiFi & Switch Controller**.
2. Select an existing WIDS Profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.
4. Select **Enable On-Wire Rogue AP Detection**.
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

To enable the rogue AP scanning feature in a custom AP profile - CLI

```
config wireless-controller wids-profile
  edit FAP220B-default
    set ap-scan enable
    set rogue-scan enable
  end
```

Exempting an AP from rogue scanning

By default, if Rogue AP Detection is enabled, it is enabled on all managed FortiAP units. Optionally, you can exempt an AP from scanning. You should be careful about doing this if your organization must perform scanning to meet PCI-DSS requirements.

To exempt an AP from rogue scanning

1. Go to **WiFi & Switch Controller > WIDS Profiles**.
2. Create a new WIDS profile and disable **Rogue AP detection**.

3. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile you wish to exempt from rogue scanning.
4. Assign the WIDS profile created in step 2.

MAC adjacency

You can adjust the maximum WiFi to Ethernet MAC difference used when determining whether an suspect AP is a rogue.

To adjust MAC adjacency

For example, to change the adjacency to 8, enter

```
config wireless-controller global
  set rogue-scan-mac-adjacency 8
end
```

Using the Rogue AP Monitor

Go to **Monitor > Rogue AP Monitor** to view the list of other wireless access points that are receivable at your location.

Information Columns

Actual columns displayed depends on **Column Settings**.

State	 Rogue AP — Use this status for unauthorized APs that On-wire status indicates are attached to your wired networks.
	 Accepted AP — Use this status for APs that are an authorized part of your network or are neighboring APs that are not a security threat. To see accepted APs in the list, select Show Accepted .
	 Unclassified — This is the initial status of a discovered AP. You can change an AP back to unclassified if you have mistakenly marked it as Rogue or Accepted.
Online Status	 Active AP
	 Inactive AP
	 Active ad-hoc WiFi device
	 Inactive ad-hoc WiFi device
SSID	The wireless service set identifier (SSID) or network name for the wireless interface.
Security Type	The type of security currently being used.
Channel	The wireless radio channel that the access point uses.
MAC Address	The MAC address of the Wireless interface.
Vendor Info	The name of the vendor.
Signal Strength	The relative signal strength of the AP. Mouse over the symbol to view the signal-to-noise ratio.
Detected By	The name or serial number of the AP unit that detected the signal.
On-wire	A green up-arrow indicates a suspected rogue, based on the on-wire detection technique. A red down-arrow indicates AP is not a suspected rogue.
First Seen	How long ago this AP was first detected.

Last Seen	How long ago this AP was last detected.
Rate	Data rate in bps.

To change the Online Status of an AP, right-click it and select Mark Accepted or Mark Rogue.

Suppressing rogue APs

In addition to monitoring rogue APs, you can actively prevent your users from connecting to them. When suppression is activated against an AP, the FortiGate WiFi controller sends deauthentication messages to the rogue AP's clients, posing as the rogue AP, and also sends deauthentication messages to the rogue AP, posing as its clients. This is done using the monitoring radio.

Before enabling this feature, verify that operation of Rogue Suppression is compliant with the applicable laws and regulations of your region.

To enable rogue AP suppression, you must enable monitoring of rogue APs with the on-wire detection technique. See "[Monitoring rogue APs](#)". The monitoring radio must be in the Dedicated Monitor mode.

To activate AP suppression against a rogue AP

1. Go to **Monitor > Rogue AP Monitor**.
2. When you see an AP listed that is a rogue detected "on-wire", select it and then select **Mark > Mark Rogue**.
3. To suppress an AP that is marked as a rogue, select it and then select **Suppress AP**.

To deactivate AP suppression

1. Go to **Monitor > Rogue AP Monitor**.
2. Select the suppressed rogue AP and then select **Suppress AP > Unsuppress AP**.

Monitoring wireless network health

To view the wireless health dashboard, go to **Monitor > WiFi Health Monitor**.

The wireless health dashboard provides a comprehensive view of the health of your network's wireless infrastructure. The dashboard includes widgets to display

- AP Status - Active, Down or missing, up for over 24 hours, rebooted in past 24 hours
- Client Count Over Time - viewable for past hour, day, or 30 days
- Top Client Count Per-AP - separate widgets for 2.4GHz and 5GHz bands
- Top Wireless Interference - separate widgets for 2.4GHz and 5GHz bands, requires spectrum analysis to be enabled on the radios
- Login Failures Information

The list of active clients also shows MAC address entries (similar to the **WiFi Client Monitor** page), making client information easy to view when opening the **Active Client** widget.

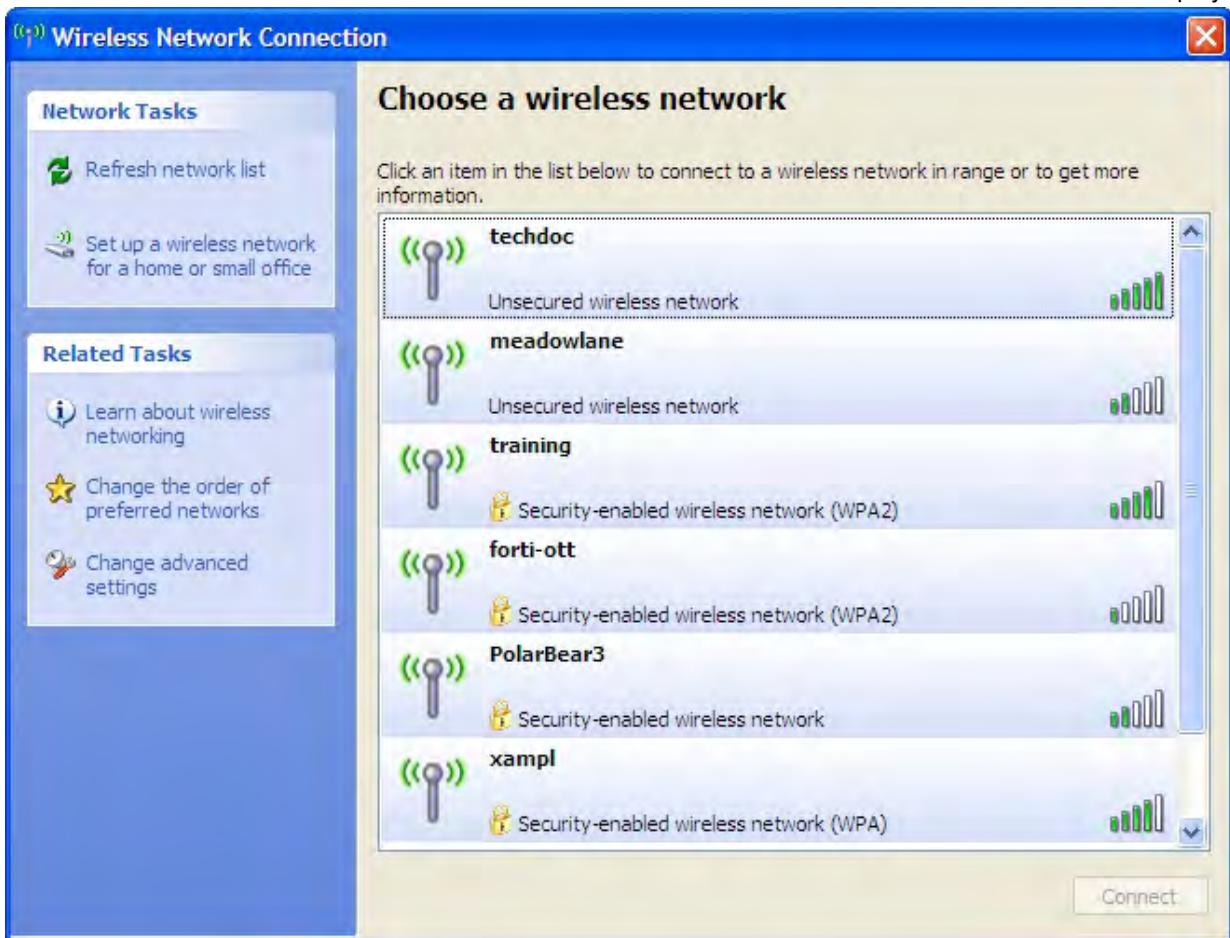

Configuring wireless network clients

This chapter shows how to configure typical wireless network clients to connect to a wireless network with WPA-Enterprise security.

Windows XP client

To configure the WPA-Enterprise network connection

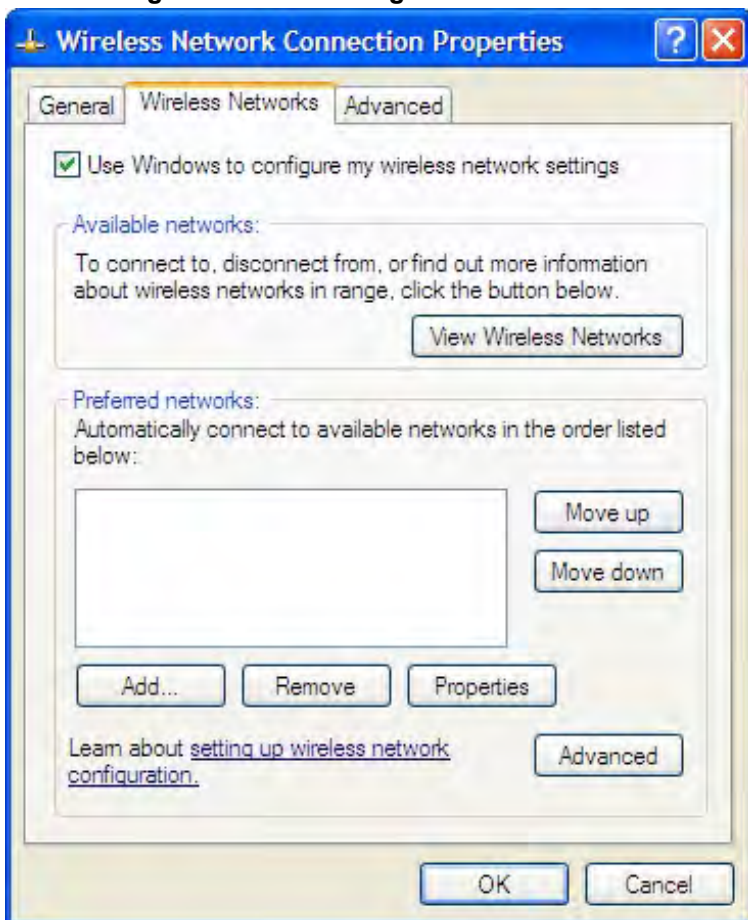

1. In the Windows Start menu, go to **Control Panel > Network Connections > Wireless Network Connection** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

If you are already connected to another wireless network, the Connection Status window displays. Select **View Wireless Networks** on the **General** tab to view the list.

If the network broadcasts its SSID, it is listed. But do not try to connect until you have completed the configuration step below. Because the network doesn't use the Windows XP default security configuration, configure the client's network settings manually before trying to connect.

2. You can configure the WPA-Enterprise network to be accessible from the **View Wireless Networks** window even if it does not broadcast its SSID.
3. Select **Change Advanced Settings** and then select the **Wireless Networks** tab.

Any existing networks that you have already configured are listed in the **Preferred Networks** list.

4. Select **Add** and enter the following information:

Wireless network properties

Association Authentication Connection

Network name (SSID): xample

☐ Connect even if this network is not broadcasting

Wireless network key

This network requires a key for the following:

Network Authentication: WPA2

Data encryption: AES

Network key:

Confirm network key:

Key index (advanced): 1

☐ The key is provided for me automatically

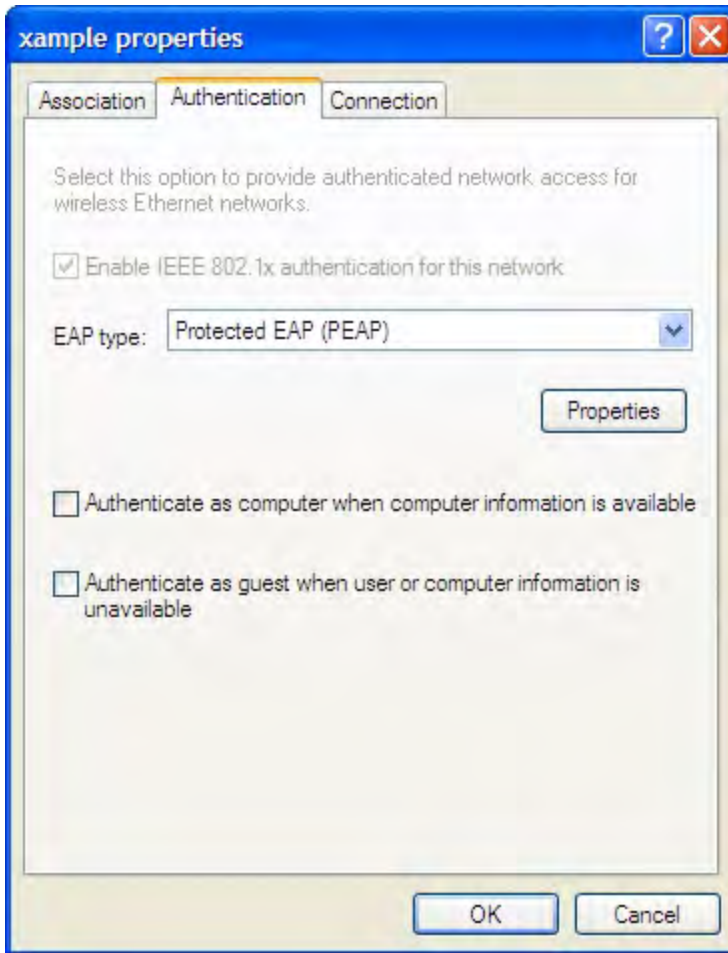

☐ This is a computer-to-computer (ad hoc) network; wireless access points are not used

OK Cancel

Network Name (SSID)	The SSID for your wireless network
Network Authentication	WPA2
Data Encryption	AES

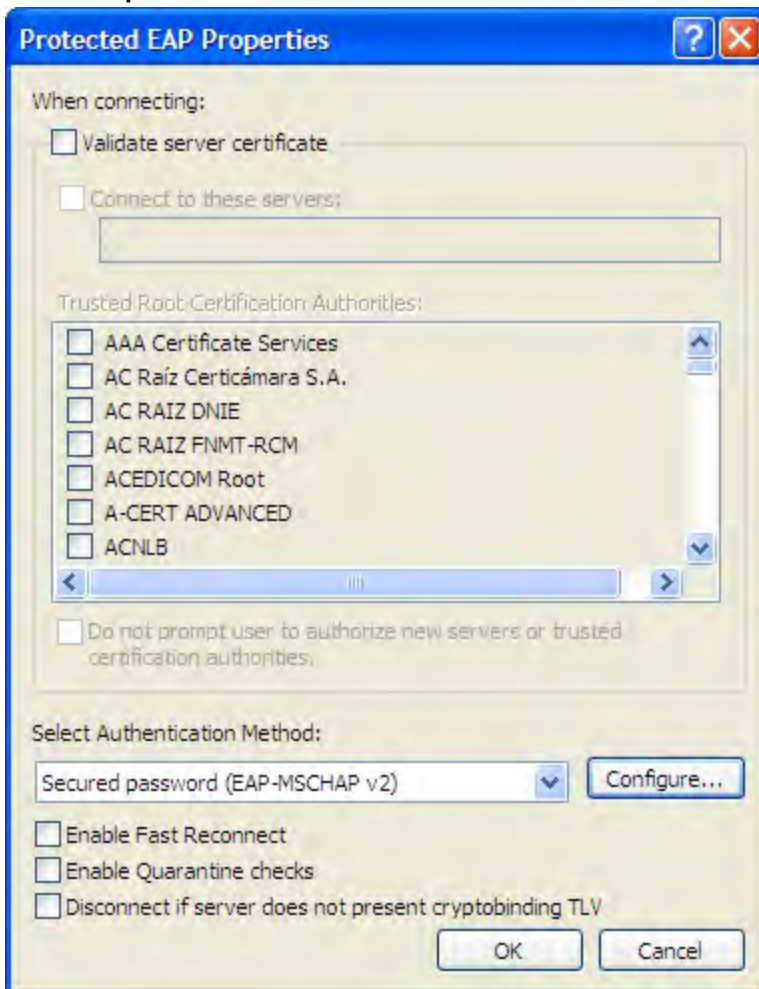

5. If this wireless network does not broadcast its SSID, select **Connect even if this network is not broadcasting** so that the network will appear in the **View Wireless Networks** list.

6. Select the **Authentication** tab.

7. In **EAP Type**, select **Protected EAP (PEAP)**.
8. Make sure that the other two authentication options are not selected.

9. Select **Properties**.

10. Make sure that **Validate server certificate** is selected.
11. Select the server certificate **Entrust Root Certification Authority**.
12. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
13. Ensure that the remaining options are not selected.
14. Select **Configure**.

15. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
16. Select **OK**. Repeat until you have closed all of the **Wireless Network Connection Properties** windows.

To connect to the WPA-Enterprise wireless network

1. Select the wireless network icon in the Notification area of the Taskbar.
2. In the **View Wireless Networks** list, select the network you just added and then select **Connect**. You might need to log off of your current wireless network and refresh the list.
3. When the following popup displays, click on it.

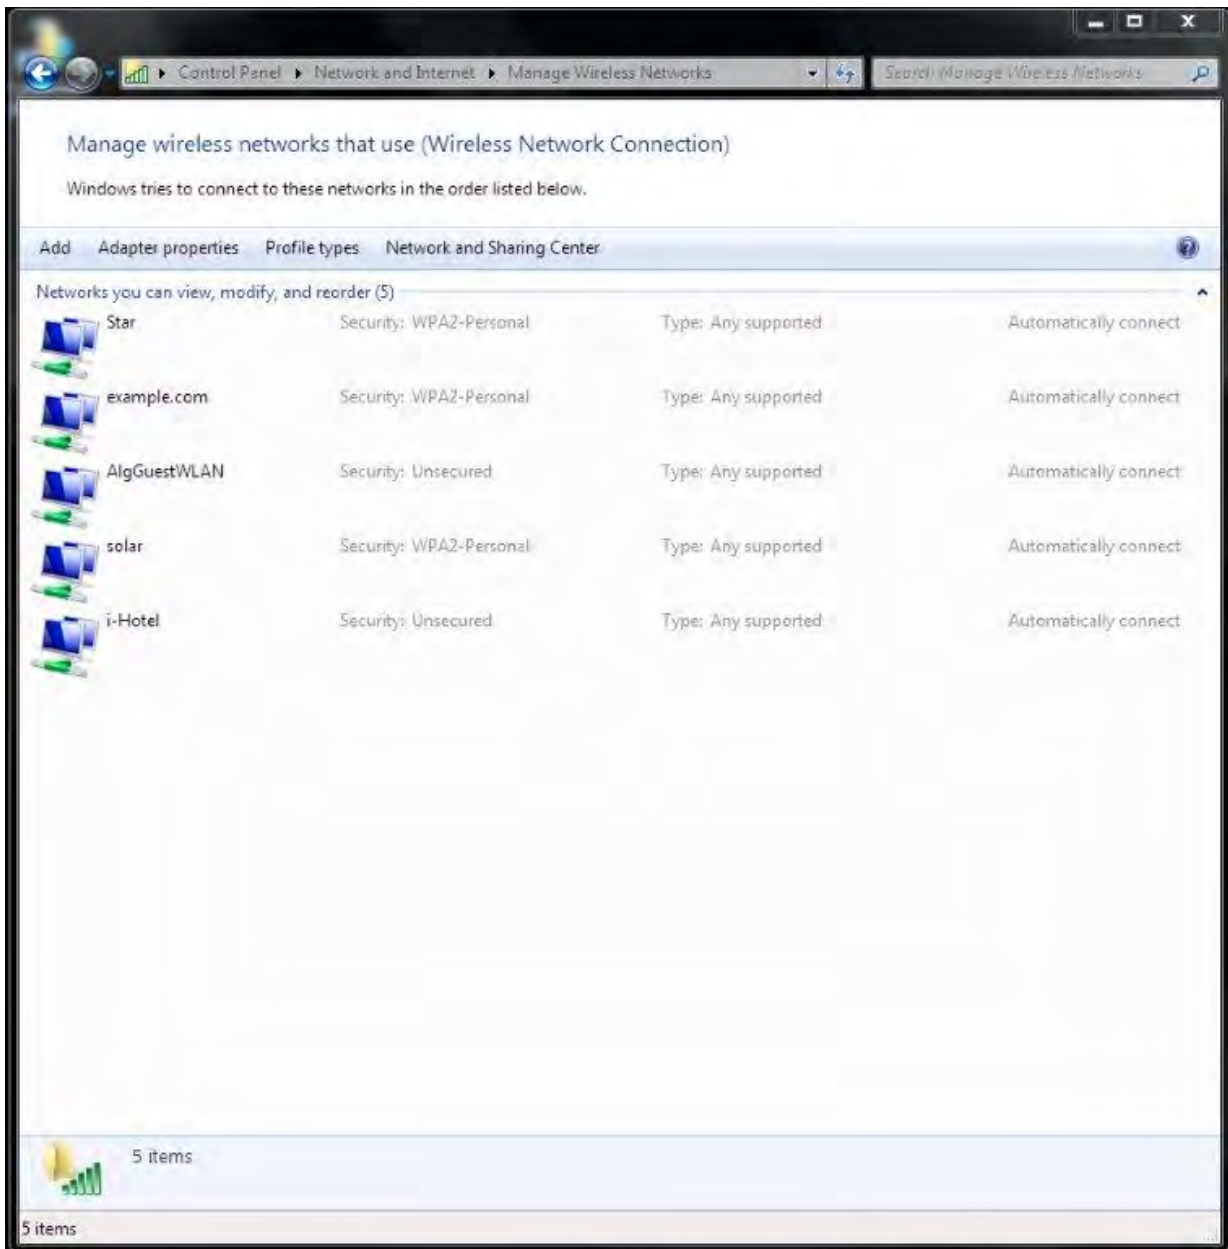

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.

In future, Windows will automatically send your credentials when you log on to this network.

Windows 7 client

1. In the Windows Start menu, go to **Control Panel > Network and Internet > Network and Sharing Center > Manage Wireless Networks** or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

2. Do one of the following:
 - If the wireless network is listed (it broadcasts its SSID), select it from the list.
 - Select **Add > Manually create a network profile**.

3. Enter the following information and select **Next**.

Manually connect to a wireless network

Enter information for the wireless network you want to add

Network name:

Security type:

Encryption type:

Security Key: ☐ Hide characters

☒ Start this connection automatically

☒ Connect even if the network is not broadcasting

Warning: If you select this option, your computer's privacy might be at risk.

Network name	Enter the SSID of the wireless network. (Required only if you selected Add.)
Security type	WPA2-Enterprise
Encryption type	AES
Start this connection automatically	Select
Connect even if the network is not broadcasting.	Select

The Wireless Network icon will display a popup requesting that you click to enter credentials for the network. Click on the popup notification.

4. In the **Enter Credentials** window, enter your wireless network **User name**, **Password**, and **Logon domain** (if applicable). Then, select **OK**.
5. Select **Change connection settings**.
6. On the **Connection** tab, select **Connect automatically when this network is in range**.
7. On the **Security** tab, select the Microsoft PEAP authentication method and then select **Settings**.

8. Make sure that **Validate server certificate** is selected.
9. Select the server certificate **Entrust Root Certification Authority**.
10. In **Select Authentication Method**, select **Secured Password (EAP-MSCHAPv2)**.
11. Select **Configure**.

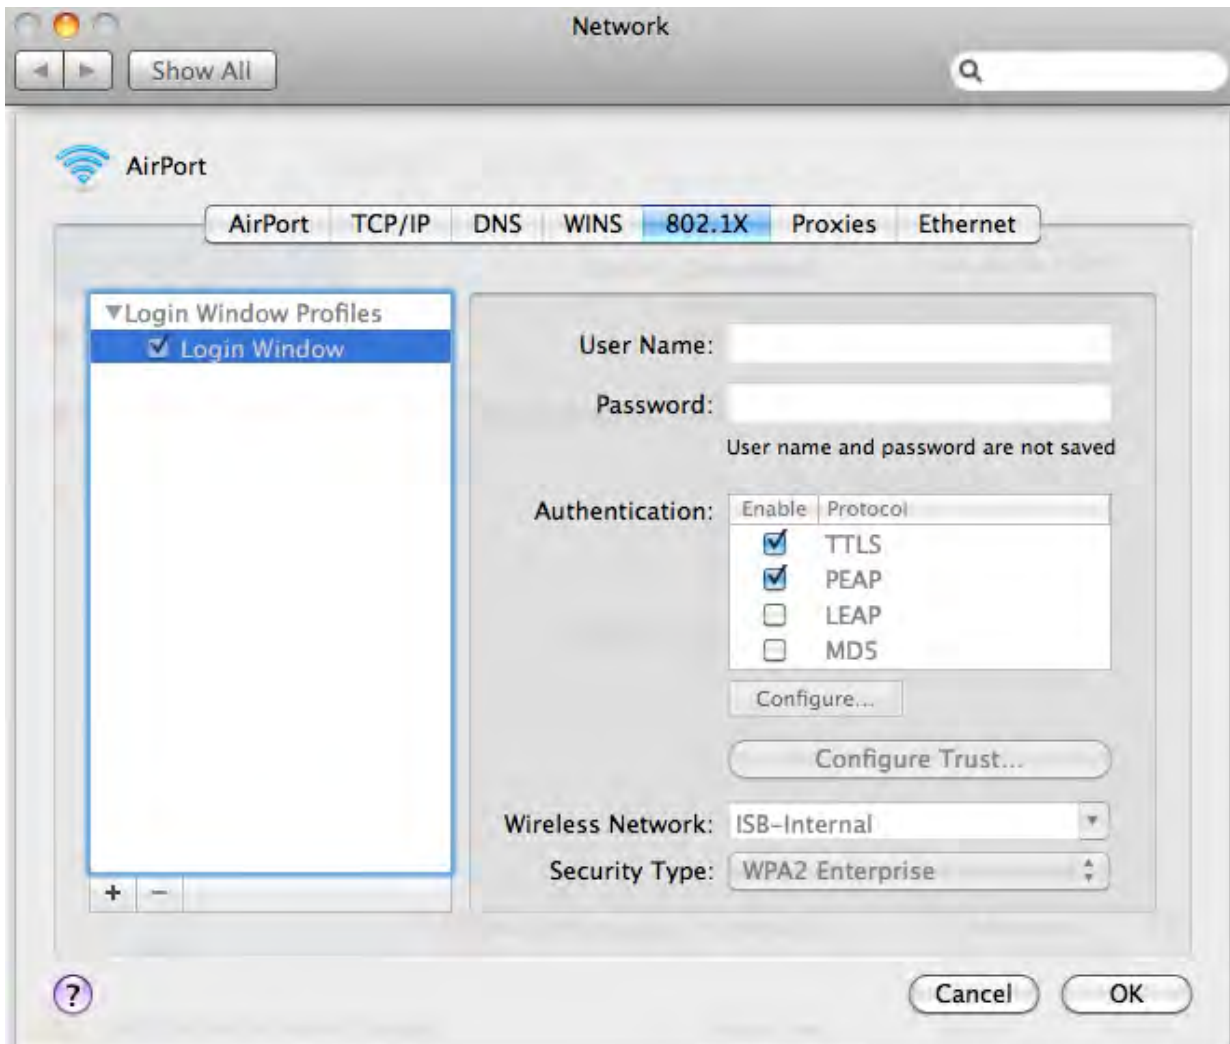

12. If your wireless network credentials are the same as your Windows logon credentials, select **Automatically use my Windows logon name and password**. Otherwise, make sure that this option is not selected.
13. Ensure that the remaining options are not selected.
14. Select **OK**. Repeat until you have closed all of the **Wireless Network Properties** windows.

Mac OS client

To configure network preferences

1. Right-click the **AirPort** icon in the toolbar and select **Open Network Preferences**.
2. Select **Advanced** and then select the **802.1X** tab.

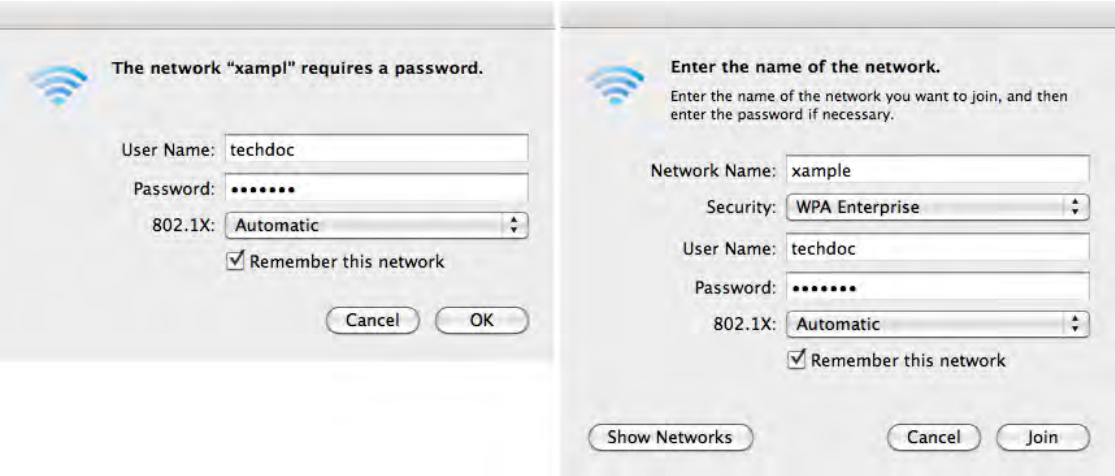

3. If there are no Login Window Profiles in the left column, select the + button and then select **Add Login Window Profile**.
4. Select the Login Window Profile and then make sure that both TTLS and PEAP are selected in **Authentication**.

To configure the WPA-Enterprise network connection

1. Select the **AirPort** icon in the toolbar.
2. Do one of the following:
 - If the network is listed, select the network from the list.
 - Select **Connect to Other Network**.

One of the following windows opens, depending on your selection.

3. Enter the following information and select **OK** or **Join**:

Network name	Enter the SSID of your wireless network. (Other network only)
Wireless Security	WPA Enterprise
802.1X	Automatic
Username Password	Enter your logon credentials for the wireless network.
Remember this network	Select.

You are connected to the wireless network.

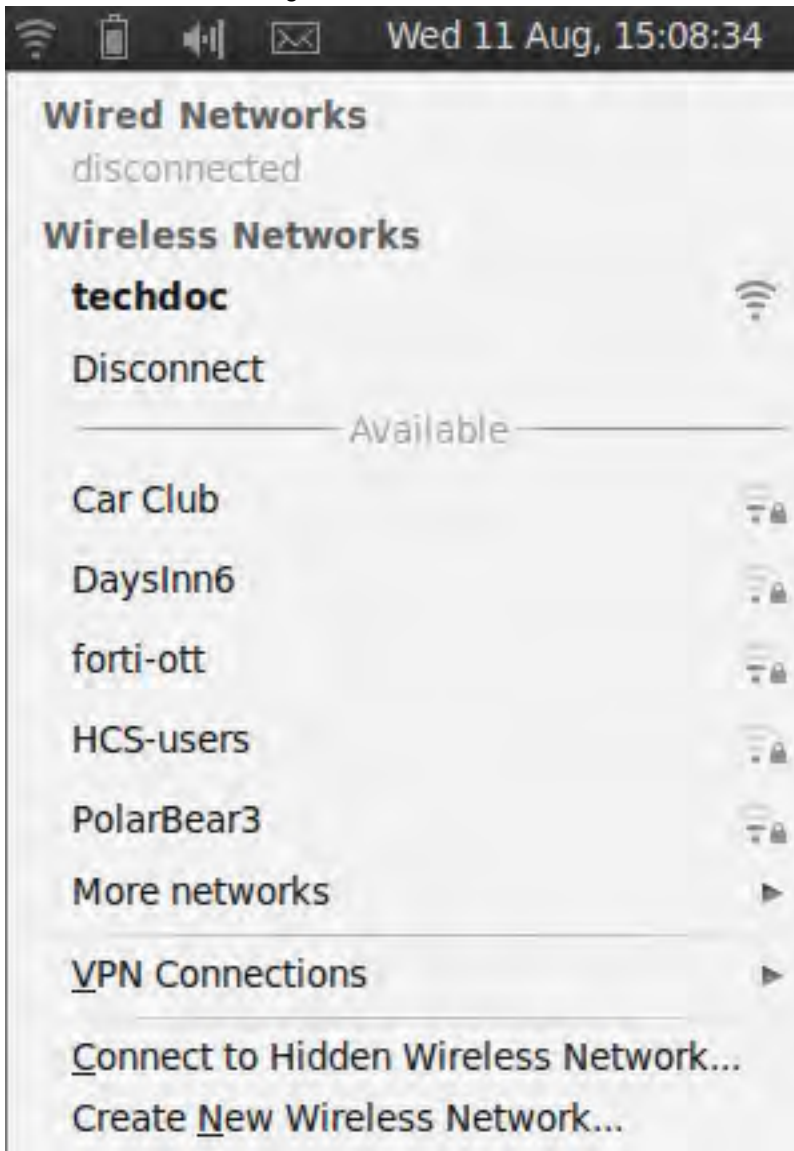

Mac OS supports only PEAP with MSCHAPv2 authentication and therefore can authenticate only to a RADIUS server, not an LDAP or TACACS+ server

Linux client

This example is based on the Ubuntu 10.04 Linux wireless client.

To connect to a WPA-Enterprise network

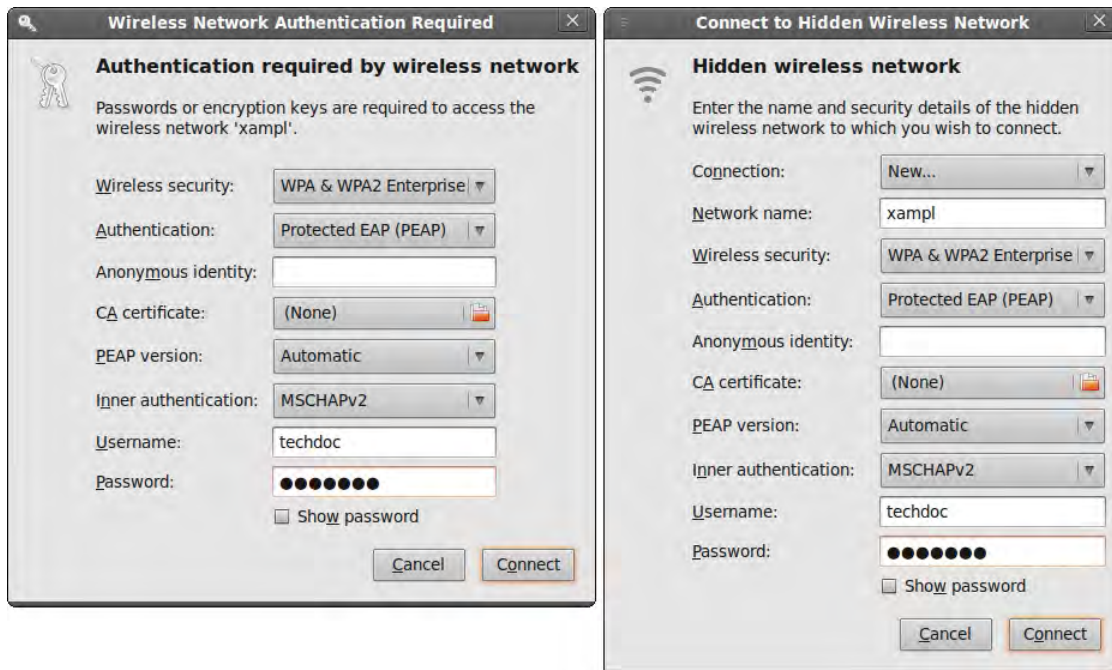

1. Select the Network Manager icon to view the Wireless Networks menu.

Wireless networks that broadcast their SSID are listed in the **Available** section of the menu. If the list is long, it is continued in the **More Networks** submenu.

2. Do one of the following:
 - Select the network from the list (also check **More Networks**).
 - Select **Connect to Hidden Wireless Network**.

One of the following windows opens, depending on your selection.

3. Enter the following information:

Connection	Leave as New . (Hidden network only)
Network name	Enter the SSID of your wireless network. (Hidden network only)
Wireless Security	WPA & WPA2 Enterprise
Authentication	Protected EAP (PEAP) for RADIUS-based authentication Tunneled TLS for TACACS+ or LDAP-based authentication
Anonymous identity	This is not required.
CA Certificate	If you want to validate the AP's certificate, select the Entrust Root Certification Authority root certificate. The default location for the certificate is /usr/share/ca-certificates/mozilla/.
PEAP version	Automatic (applies only to PEAP)
Inner authentication	MSCHAPv2 for RADIUS-based authentication PAP or CHAP for TACACS+ or LDAP-based authentication
Username	Enter your logon credentials for the wireless network.
Password	

4. If you did not select a CA Certificate above, you are asked to do so. Select Ignore.

5. Select **Connect**. You are connected to the wireless network.

To connect to a WPA-Enterprise network

1. Select the Network Manager icon to view the Wireless Networks menu.
2. Select the network from the list (also check **More Networks**).
If your network is not listed (but was configured), select **Connect to Hidden Wireless Network**, select your network from the Connection drop-down list, and then select **Connect**.

Troubleshooting

Using tools provided in your operating system, you can find the source of common wireless networking problems.

Checking that client received IP address and DNS server information

Windows XP

1. Double-click the network icon in the taskbar to display the **Wireless Network Connection Status** window. Check that the correct network is listed in the **Connection** section.
2. Select the **Support** tab.
Check that the **Address Type** is **Assigned by DHCP**. Check that the **IP Address**, **Subnet Mask**, and **Default Gateway** values are valid.
3. Select **Details** to view the DNS server addresses.
The listed address should be the DNS serves that were assigned to the WAP. Usually a wireless network that provides access to the private LAN is assigned the same DNS servers as the wired private LAN. A wireless network that provides guest or customer users access to the Internet is usually assigned public DNS servers.
4. If any of the addresses are missing, select **Repair**.
If the repair procedure doesn't correct the problem, check your network settings.

Mac OS

1. From the Apple menu, open **System Preferences > Network**.
2. Select **AirPort** and then select **Configure**.

3. On the **Network** page, select the **TCP/IP** tab.

4. If there is no IP address or the IP address starts with 169, select **Renew DHCP Lease**.
5. To check DNS server addresses, open a terminal window and enter the following command:

```
cat /etc/resolv.conf
```

Check the listed nameserver addresses. A network for employees should use the wired private LAN DNS server. A network for guests should specify a public DNS server.

Linux

This example is based on the Ubuntu 10.04 Linux wireless client.

1. Right-click the Network Manager icon and select **Connection Information**.

2. Check the IP address, and DNS settings. If they are incorrect, check your network settings.

Wireless network examples

This chapter provides an example wireless network configuration.

Basic wireless network

This example uses automatic configuration to set up a basic wireless network.

To configure this wireless network, you must:

- Configure authentication for wireless users
- Configure the SSID (WiFi network interface)
- Add the SSID to the FortiAP Profile
- Configure the firewall policy
- Configure and connect FortiAP units

Configuring authentication for wireless users

You need to configure user accounts and add the users to a user group. This example shows only one account, but multiple accounts can be added as user group members.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.
3. Enter a **User Name** and **Password** and then click **Next**.
4. Click **Next**.
5. Make sure that **Enable** is selected and then click **Create**.

To configure the WiFi user group - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	wlan_users
Type	Firewall
Members	Add users.

To configure a WiFi user and the WiFi user group - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
config user group
```

```
edit "wlan_users"
  set member "user01"
end
```

Configuring the SSID

First, establish the SSID (network interface) for the network. This is independent of the number of physical access points that will be deployed. The network assigns IP addresses using DHCP.

To configure the SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter the following information and select **OK**:

Interface Name	example_wifi_if
Traffic Mode	Tunnel to Wireless Controller
IP/Network Mask	10.10.110.1/24
Administrative Access	Ping (to assist with testing)
DHCP Server	Enable
Address Range	10.10.110.2 - 10.10.110.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
SSID	example_wifi
Security Mode	WPA2 Enterprise
Authentication	Local, select wlan_users user group.
Leave other settings at their default values.	

To configure the SSID - CLI

```
config wireless-controller vap
  edit example_wifi_if
    set ssid "example_wifi"
    set broadcast-ssid enable
    set security wpa-enterprise
    set auth usergroup
    set usergroup wlan_users
    set schedule always
  end
config system interface
  edit example_wifi_if
    set ip 10.10.110.1 255.255.255.0
  end
config system dhcp server
```

```
edit 0
    set default-gateway 10.10.110.1
    set dns-service default
    set interface "example_wifi_if"
    config ip-range
        edit 1
            set end-ip 10.10.110.199
            set start-ip 10.10.110.2
        end
    set netmask 255.255.255.0
end
```

Adding the SSID to the FortiAP Profile

The radio portion of the FortiAP configuration is contained in the FortiAP Profile. By default, there is a profile for each platform (FortiAP model). You can create additional profiles if needed. The SSID needs to be specified in the profile.

To add the SSID to the FortiAP Profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and edit the profile for your model of FortiAP unit.
2. In **Radio 1** and **Radio 2**, add example_wifi in **SSID**.
3. Select **OK**.

Configuring security policies

A security policy is needed to enable WiFi users to access the Internet on port1. First you create firewall address for the WiFi network, then you create the example_wifi to port1 policy.

To create a firewall address for WiFi users - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New > Address**, enter the following information and select **OK**.

Name	wlan_user_net
Type	IP/Netmask
Subnet / IP Range	10.10.110.0/24
Interface	example_wifi_if
Show in Address List	Enabled

To create a firewall address for WiFi users - CLI

```
config firewall address
    edit "wlan_user_net"
        set associated-interface "example_wifi_if"
        set subnet 10.10.110.0 255.255.255.0
    end
```

To create a security policy for WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_wifi_if
Source Address	wlan_user_net
Outgoing Interface	port1
Destination Address	All
Schedule	always
Service	ALL
Action	ACCEPT
NAT	ON. Select Use Destination Interface Address (default).
Leave other settings at their default values.	

To create a firewall policy for WiFi users - CLI

```
config firewall policy
edit 0
set srcintf "example_wifi"
set dstintf "port1"
set srcaddr "wlan_user_net"
set dstaddr "all"
set schedule always
set service ALL
set action accept
set nat enable
end
```

Connecting the FortiAP units

You need to connect each FortiAP unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Dedicated to Extension Device** and set the **IP/Network Mask** to 192.168.8.1/255.255.255.0.
3. Select **OK**.

This procedure automatically configures a DHCP server for the AP units.

To configure the interface for the AP unit - CLI

```
config system interface
edit port3
set mode static
set ip 192.168.8.1 255.255.255.0
end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
edit 0
set interface port3
config exclude-range
edit 1
set end-ip 192.168.8.1
set start-ip 192.168.8.1
end
config ip-range
edit 1
set end-ip 192.168.8.254
set start-ip 192.168.8.2
end
set netmask 255.255.255.0
set vci-match enable
set vci-string "FortiAP"
end
```

To connect a FortiAP unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
Recognition of the FortiAP unit can take up to two minutes.
If FortiAP units are connected but cannot be recognized, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize**.
6. In **FortiAP Profile**, select the default profile for the FortiAP model.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter

```
config wireless-controller wtp
```

3. Wait 30 seconds, then enter `get`.

Retry the `get` command every 15 seconds or so until the unit is listed, like this:

```
== [ FAP22B3U10600118 ]
wtp-id: FAP22B3U10600118
```

4. Edit the discovered FortiAP unit like this:

```
edit FAP22B3U10600118
  set admin enable
end
```

5. Repeat Steps 2 through 4 for each FortiAP unit.

A more complex example

This example creates multiple networks and uses custom AP profiles.

Scenario

In this example, Example Co. provides two wireless networks, one for its employees and the other for customers or other guests of its business. Guest users have access only to the Internet, not to the company's private network. The equipment for these WiFi networks consists of FortiAP-220B units controlled by a FortiGate unit.

The employee network operates in 802.11n mode on both the 2.4GHz and 5GHz bands. Client IP addresses are in the 10.10.120.0/24 subnet, with 10.10.120.1 the IP address of the WAP. The guest network also operates in 802.11n mode, but only on the 2.4GHz band. Client IP addresses are on the 10.10.115.0/24 subnet, with 10.10.115.1 the IP address of the WAP.

On FortiAP-220B units, the 802.11n mode also supports 802.11g and 802.11b clients on the 2.4GHz band and 802.11a clients on the 5GHz band.

The guest network WAP broadcasts its SSID, the employee network WAP does not.

The employees network uses WPA-Enterprise authentication through a FortiGate user group. The guest network features a captive portal. When a guest first tries to connect to the Internet, a login page requests logon credentials. Guests use numbered guest accounts authenticated by RADIUS. The captive portal for the guests includes a disclaimer page.

In this example, the FortiAP units connect to port 3 and are assigned addresses on the 192.168.8.0/24 subnet.

Configuration

To configure these wireless networks, you must:

- Configure authentication for wireless users
- Configure the SSIDs (network interfaces)
- Configure the AP profile
- Configure the WiFi LAN interface and a DHCP server
- Configure firewall policies

Configuring authentication for employee wireless users

Employees have user accounts on the FortiGate unit. This example shows creation of one user account, but you can create multiple accounts and add them as members to the user group.

To configure a WiFi user - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Select **Local User** and then click **Next**.
3. Enter a **User Name** and **Password** and then click **Next**.

4. Click **Next**.
5. Make sure that **Enable** is selected and then click **Create**.

To configure the user group for employee access - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	employee-group
Type	Firewall
Members	Add users.

To configure a WiFi user and the user group for employee access - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
config user group
  edit "employee-group"
    set member "user01"
  end
```

The user authentication setup will be complete when you select the employee-group in the SSID configuration.

Configuring authentication for guest wireless users

Guests are assigned temporary user accounts created on a RADIUS server. The RADIUS server stores each user's group name in the Fortinet-Group-Name attribute. Wireless users are in the group named "wireless".

The FortiGate unit must be configured to access the RADIUS server.

To configure the FortiGate unit to access the guest RADIUS server - web-based manager

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select OK:

Name	guestRADIUS
Primary Server IP/Name	10.11.102.100
Primary Server Secret	grikfwpfdfg
Secondary Server IP/Name	Optional
Secondary Server Secret	Optional
Authentication Scheme	Use default, unless server requires otherwise.
Leave other settings at their default values.	

To configure the FortiGate unit to access the guest RADIUS server - CLI

```

config user radius
  edit guestRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret grikfwpfdg
  end

```

To configure the user group for guest access - web-based manager

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	guest-group
Type	Firewall
Members	Leave empty.

3. Select **Create new**.
4. Enter:

Remote Server	Select guestRADIUS .
Groups	Select wireless

5. Select **OK**.

To configure the user group for guest access - CLI

```

config user group
  edit "guest-group"
    set member "guestRADIUS"
    config match
      edit 0
        set server-name "guestRADIUS"
        set group-name "wireless"
      end
    end
  end

```

The user authentication setup will be complete when you select the guest-group user group in the SSID configuration.

Configuring the SSIDs

First, establish the SSIDs (network interfaces) for the employee and guest networks. This is independent of the number of physical access points that will be deployed. Both networks assign IP addresses using DHCP.

To configure the employee SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New > SSID**.
2. Enter the following information and select **OK**:

Interface Name	example_inc
Traffic Mode	Tunnel to Wireless Controller
IP/Netmask	10.10.120.1/24
Administrative Access	Ping (to assist with testing)
Enable DHCP	Enable
Address Range	10.10.120.2 - 10.10.120.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
SSID	example_inc
Security Mode	WPA/WPA2-Enterprise
Authentication	Select Local , then select employee-group .
Leave other settings at their default values.	

To configure the employee SSID - CLI

```
config wireless-controller vap
  edit example_inc
    set ssid "example_inc"
    set security wpa-enterprise
    set auth usergroup
    set usergroup employee-group
    set schedule always
  end
config system interface
  edit example_inc
    set ip 10.10.120.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_inc
    config ip-range
      edit 1
        set end-ip 10.10.120.199
        set start-ip 10.10.120.2
      end
    set lease-time 7200
    set netmask 255.255.255.0
  end
```

To configure the example_guest SSID - web-based manager

1. Go to **WiFi & Switch Controller > SSID** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_guest
IP/Netmask	10.10.115.1/24
Administrative Access	Ping (to assist with testing)
Enable DHCP	Enable
Address Range	10.10.115.2 - 10.10.115.50
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
SSID	example_guest
Security Mode	Captive Portal
Portal Type	Authentication
Authentication Portal	Local
User Groups	Select guest-group
Leave other settings at their default values.	

To configure the example_guest SSID - CLI

```

config wireless-controller vap
  edit example_guest
    set ssid "example_guest"
    set security captive-portal
    set selected-usergroups guest-group
    set schedule always
  end
config system interface
  edit example_guest
    set ip 10.10.115.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.115.1
    set dns-service default
    set interface "example_guest"
    config ip-range
      edit 1
        set end-ip 10.10.115.50
        set start-ip 10.10.115.2
      end
    set lease-time 7200
  end
end

```

```
set netmask 255.255.255.0
end
```

Configuring the FortiAP profile

The FortiAP Profile defines the radio settings for the networks. The profile provides access to both Radio 1 (2.4GHz) and Radio 2 (5GHz) for the employee virtual AP, but provides access only to Radio 1 for the guest virtual AP.

To configure the FortiAP Profile - web-based manager

1. Go to **WiFi & Switch Controller > FortiAP Profiles** and select **Create New**.
2. Enter the following information and select **OK**:

Name	example_AP
Platform	FAP220B
Radio 1	
Mode	Access Point
Band	802.11n
Channel	Select 1, 6, and 11.
Tx Power	100%
SSID	Select SSIDs and select example_inc and example_guest .
Radio 2	
Mode	Access Point
Band	802.11n_5G
Channel	Select all.
Tx Power	100%
SSID	Select SSIDs and select example_inc .

To configure the AP Profile - CLI

```
config wireless-controller wtp-profile
  edit "example_AP"
    config platform
      set type 220B
    end
    config radio-1
      set ap-bgscan enable
      set band 802.11n
      set channel "1" "6" "11"
      set vaps "example_inc" "example_guest"
    end
    config radio-2
```

```

set ap-bgscan enable
set band 802.11n-5G
set channel "36" "40" "44" "48" "149" "153" "157" "161" "165"
set vaps "example_inc"
end

```

Configuring firewall policies

Identity-based firewall policies are needed to enable the WLAN users to access the Internet on Port1. First you create firewall addresses for employee and guest users, then you create the firewall policies.

To create firewall addresses for employee and guest WiFi users

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information and select **OK**.

Address Name	employee-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.120.0/24
Interface	example_inc

3. Select **Create New**, enter the following information and select **OK**.

Address Name	guest-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.115.0/24
Interface	example_guest

To create firewall policies for employee WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_inc
Source Address	employee-wifi-net
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select security profile for wireless users.
4. Select **OK**.
5. Repeat steps 1 through 4 but select Internal as the Destination Interface/Zone to provides access to the ExampleCo private network.

To create firewall policies for employee WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "employee_inc"
    set dstintf "port1"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
    set schedule "always"
  next
  edit 0
    set srcintf "employee_inc"
    set dstintf "internal"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
    set schedule "always"
end
```

To create a firewall policy for guest WiFi users - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**:

Incoming Interface	example_guest
Source Address	guest-wifi-net
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select **UTM** and set up UTM features for wireless users.
4. Select **OK**.

To create a firewall policy for guest WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_guest"
    set dstintf "port1"
    set srcaddr "guest-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP-220A unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to **Network > Interfaces** and edit the port3 interface.
2. Set the **Addressing mode** to **Dedicated to Extension Device** and set the **IP/Netmask** to 192.168.8.1/255.255.255.0.
This step automatically configures a DHCP server for the AP units.
3. Select **OK**.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
  end
```

To connect a FortiAP-220A unit - web-based manager

1. Go to **WiFi & Switch Controller > Managed FortiAPs**.
2. Connect the FortiAP unit to port 3.
3. Periodically select **Refresh** while waiting for the FortiAP unit to be listed.
Recognition of the FortiAP unit can take up to two minutes.
If there is persistent difficulty recognizing FortiAP units, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.
The **Edit Managed Access Point** window opens.
5. In **State**, select **Authorize**.
6. In the **AP Profile**, select **[Change]** and then select the **example_AP** profile.
7. Select **OK**.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP-220A unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter:

```
config wireless-controller wtp
```
3. Wait 30 seconds, then enter `get`.
Retry the `get` command every 15 seconds or so until the unit is listed, like this:

```
== [ FAP22A3U10600118 ]  
wtp-id: FAP22A3U10600118
```
4. Edit the discovered FortiAP unit like this:

```
edit FAP22A3U10600118  
    set admin enable  
    set wtp-profile example_AP  
end
```
5. Repeat Steps 2 through 4 for each FortiAP unit.

Managing a FortiAP with FortiCloud

This chapter provides a few FortiCloud-managed FortiAP configuration examples.

You can register for a free FortiCloud account at www.forticloud.com.

For a video tutorial of how to configure and manage a FortiAP-S device from FortiCloud, follow the link below:

- [How to configure and Manage FortiAP-S from FortiCloud](#)

FortiCloud-managed FortiAP WiFi

In this example, you use FortiCloud to configure a single FortiAP-221C, creating a working WiFi network without a FortiGate unit.

FortiCloud remote management is supported on FortiAP models 221C and 320C.

For this configuration, the FortiAP-221C unit is running version 5.2 firmware. You will create a simple network that uses WPA-Personal authentication.

You can register for a free FortiCloud account at www.forticloud.com.

To create the WiFi network without a FortiGate unit, you must:

- Add your FortiAP to FortiCloud
- Configure the SSID
- Configure the AP platform profile
- Deploy the AP with the profile

Adding your FortiAP to FortiCloud

You need to add the FortiAP unit to your FortiCloud account. This is done through a unique key that can be found under the FortiAP unit.

To add a FortiAP to FortiCloud

1. Connect the FortiAP Ethernet interface to a network that provides access to the Internet.
2. Open a web browser and navigate to the FortiCloud main page and select **+ AP Network**.
3. Enter an **AP Network Name** and **AP Password**. This password is used to locally log in to the AP as the administrator. It will be set to all APs in this AP network.
4. Set the correct **Time Zone** and select **Submit**.

Configuring the SSID

You must establish the SSID (network interface) for the WiFi network.

To configure the SSID

1. Select the FortiAP you just created from the home page. You will then be prompted to add an SSID for the AP Network.
In the interface, this is under **Configure > SSIDs**.

2. In **Access Control**, enter the name of your SSID, set **Authentication** to **WPA2-Personal**, enter the **Pre-shared Key**, and select **Next**.
3. In **Security**, enable security features as required (select from **AntiVirus**, **Intrusion Prevention**, **Block Botnet**, **Web Access**, and **Application Control**) and select **Next**.
4. In **Availability**, make sure to leave **5 GHz** enabled, configure a schedule as required, and select **Next**.
5. Review your SSID in **Preview**, then select **Apply**.

Configuring the AP platform profile

The radio portion of the FortiAP configuration is contained in the FortiAP platform profile. By default, there is a profile for each platform (FortiAP model). The SSID needs to be specified in the profile.

To configure the AP profile

1. Go to **Configure > AP Profile** and edit the AP Profile for your FortiAP model (mouse-over the AP Profile to reveal the **Edit** button).
2. Enable the SSID configured earlier for both **Radio 1** and **Radio 2**, for 5GHz coverage.

Deploying the AP with the platform profile

With the SSID and platform profile configured, you must deploy the AP by entering the FortiCloud key for the FortiAP.

To deploy the AP

1. Go to **Configure > Deploy APs**. Here you will be prompted to enter the FortiCloud key, which can be found on the same label as the FortiAP unit's serial number, and select **Submit**.

If you have a FortiAP model that does *not* include a FortiCloud key, you can still add the device to the network. To learn how, see the [FortiCloud-managed FortiAP WiFi without a key](#) configuration.

2. In **Set Platform Profiles**, select the platform profile you created earlier and select **Next**.
3. Follow the rest of the deployment wizard. Select **Submit** when completed.

You will now be able to connect to the wireless network and browse the Internet. On the FortiCloud website, go to **Monitor > Report** where you can view monitoring information such as **Traffic by Period**, **Client Count by Period**, and more.

FortiCloud-managed FortiAP WiFi without a key

You can manage your FortiAP-based wireless network with FortiCloud even if your FortiAP has no FortiCloud key.

For this example, you will need to have already pre-configured your FortiAP unit with your FortiCloud account credentials. For more information on how to do this, or if your FortiAP has a FortiCloud key (on the serial number label), see the [FortiCloud-managed FortiAP WiFi](#) configuration.

You can register for a free FortiCloud account at www.forticloud.com.

To create the WiFi network without a FortiCloud key, you must:

- Configure the FortiAP unit
- Add the FortiAP unit to your FortiCloud account
- Configure the FortiAP

Configuring the FortiAP unit

You need to connect and configure the FortiAP unit through the web-based manager of the FortiGate.

To configure the FortiAP unit - web-based manager

1. Connect your computer to the FortiAP Ethernet port. The FortiAP's default IP address is 192.168.1.2. The computer should have an address on the same subnet, 192.168.1.3 for example.
2. Using a browser, log in to the FortiAP as *admin*. Leave the password field empty.
3. In **WTP-Configuration**, select **FortiCloud** and enter your FortiCloud credentials. Select **Apply**.
The FortiAP is now ready to connect to FortiCloud via the Internet.

Adding the FortiAP unit to your FortiCloud account

The FortiAP must be added to the FortiCloud account that has a WiFi network already configured for it.

For an example of creating a WiFi network on FortiCloud, see [FortiCloud-managed FortiAP WiFi on page 1526](#).

To add the FortiAP to FortiCloud

1. Connect the FortiAP Ethernet cable to a network that connects to the Internet.
Restore your computer to its normal network configuration and log on to FortiCloud.
2. From the **Home** screen, go to **Inventory > AP Inventory**. Your FortiAP should be listed.
3. Then go back to the Home screen, select your AP network, and go to **Deploy APs**.
4. Select your listed FortiAP and select **Next**.
5. Make sure your platform profile is selected from the dropdown menu, and select **Next**.
6. In **Preview**, select **Deploy**.
The device will now appear listed under **Access Points**.

You will now be able to connect to the wireless network and browse the Internet. On the FortiCloud website, go to **Monitor > Report** where you can view monitoring information such as **Traffic by Period**, **Client Count by Period**, and more.

Using a FortiWiFi unit as a client

A FortiWiFi unit by default operates as a wireless access point. But a FortiWiFi unit can also operate as a wireless client, connecting the FortiGate unit to another wireless network.

Use of client mode

In client mode, the FortiWiFi unit connects to a remote WiFi access point to access other networks or the Internet. This is most useful when the FortiWiFi unit is in a location that does not have a wired infrastructure.

For example, in a warehouse where shipping and receiving are on opposite sides of the building, running cables might not be an option due to the warehouse environment. The FortiWiFi unit can support wired users using its Ethernet ports and can connect to another access point wirelessly as a client. This connects the wired users to the network using the 802.11 WiFi standard as a backbone.

Note that in client mode the FortiWiFi unit cannot operate as an AP. WiFi clients cannot see or connect to the FortiWiFi unit in Client mode.

FortiWiFi unit in Client mode

Configuring client mode

To set up the FortiAP unit as a WiFi client, you must use the CLI. Before you do this, be sure to remove any AP WiFi configurations such as SSIDs, DHCP servers, policies, and so on.

To configure wireless client mode

1. Change the WiFi mode to client.

In the CLI, enter the following commands:

```
config system global
    set wireless-mode client
end
```

Respond “y” when asked if you want to continue. The FortiWiFi unit will reboot.

2. Configure the WiFi interface settings.

For example, to configure the client for WPA-Personal authentication on the **our_wifi** SSID with passphrase **justforus**, enter the following in the CLI:

```
config system interface
    edit wifi
        set mode dhcp
        config wifi-networks
            edit 0
                set wifi-ssid our_wifi
                set wifi-security wpa-personal
                set wifi-passphrase "justforus"
            end
        end
    end
```

The WiFi interface client_wifi will receive an IP address using DHCP.

3. Configure a wifi to port1 policy.

You can use either CLI or web-based manager to do this. The important settings are:

Incoming Interface (srcintf)	wifi
Source Address (srcaddr)	all
Outgoing Interface (dstintf)	port1
Destination Address (dstaddr)	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Selected

Controlled AP selection support in FWF client mode

Use the following CLI commands to provide a more controlled AP selection method (supported in FortiWiFi client mode).

Syntax

```
config system interface
  edit {name}
    set wifi-ap-band {any | 5g-preferred | 5g-only}
  next
end
```

Support for location-based services

FortiOS supports location-based services by collecting information about WiFi devices near FortiGate-managed access points, even if the devices don't associate with the network.

Overview

WiFi devices broadcast packets as they search for available networks. The FortiGate WiFi controller can collect information about the interval, duration, and signal strength of these packets. The Euclid Analytics service uses this information to track the movements of the device owner. A typical application of this technology is to analyze shopper behavior in a shopping center. Which stores do people walk past? Which window displays do they stop to look at? Which stores do they enter and how long do they spend there? The shoppers are not personally identified, each is known only by the MAC address of their WiFi device.

After enabling location tracking on the FortiGate unit, you can confirm that the feature is working by using a specialized diagnostic command to view the raw tracking data. The Euclid Analytics service obtains the same data in its proprietary format using a JSON inquiry through the FortiGate unit's web-based manager interface.

Configuring location tracking

You can enable location tracking in any FortiAP profile, using the CLI. Location tracking is part of location-based services. Set the `station-locate` field to `enable`. For example:

```
config wireless-controller wtp-profile
  edit "FAP220B-locate"
    set ap-country US
    config platform
      set type 220B
    end
    config lbs
      set station-locate enable
    end
  end
```

Automatic deletion of outdated presence data

The FortiGate generates a log entry only the first time that `station-locate` detects a mobile client. No log is generated for clients that have been detected before. To log repeat client visits, previous station presence data must be deleted (flushed). The `sta-locate-timer` can flush this data periodically. The default period is 1800 seconds (30 minutes). The timer can be set to any value between 1 and 86400 seconds (24 hours). A setting of 0 disables the flush, meaning a client is logged only on the very first visit.

The timer is one of the wireless controller timers and it can be set in the CLI. For example:

```
config wireless-controller timers
  set sta-locate-timer 1800
end
```

The `sta-locate-timer` should not be set to less than the `sta-capability-timer` (default 30 seconds) because that could cause duplicate logs to be generated.

FortiPresence push REST API

When the FortiGate is located on a private IP network, the FortiPresence server cannot poll the FortiGate for information. Instead, the FortiGate must be configured to push the information to the FortiPresence server.

Enter the following command:

```
config wireless-controller wtp-profile
  edit "FP223B-GuestWiFi"
    config lbs
      set fortipresence {enable | disable}
      set fortipresence-server <ip-address> Default is 3000.
      set fortipresence-port <port>
      set fortipresence-secret <password>
      set fortipresence-project <name>
      set fortipresence-frequency <5-65535> Default is 30.
      set fortipresence-rogue {enable | disable} Enable/disable reporting of Rogue APs.
      set fortipresence-unassoc {enable | disable} Enable/disable reporting of unassociated devices.
    end
  end
end
```

Viewing device location data on the FortiGate unit

You can use the FortiGate CLI to list located devices. This is mainly useful to confirm that the location data feature is working. You can also reset device location data.

To list located devices

```
diag wireless-controller wlac -c sta-locate
```

To reset device location data

```
diag wireless-controller wlac -c sta-locate-reset
```

Example output

The following output shows data for three WiFi devices.

```
FWF60C3G11004319 # diagnose wireless-controller wlac -c sta-locate
sta_mac vfid rid base_mac freq_lst frm_cnt frm_fst frm_last intv_sum intv2_sum intv3_
sum intv_min intv_max signal_sum signal2_sum signal3_sum sig_min sig_max sig_fst
sig_last ap

00:0b:6b:22:82:61 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 257 708 56 651 1836 6441 0 12 -21832
1855438 -157758796 -88 -81 -84 -88 0

00:db:df:24:1a:67 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 42 1666 41 1625 97210 5831613 0 60 -3608
310072 -26658680 -90 -83 -85 -89 0

10:68:3f:50:22:29 0
FAP22B3U11005354 0 0 00:09:0f:f1:bb:e4 5745 102 1623 58 1565 94136 5664566 0 60 -8025
631703 -49751433 -84 -75 -78 -79 0
```

The output for each device appears on two lines. The first line contains only the device MAC address and the VLAN ID. The second line begins with the ID (serial number) of the FortiWiFi or FortiAP unit that detected the device, the AP's MAC address, and then the fields that the Euclid service uses. Because of its length, this line wraps around and displays as multiple lines.

Troubleshooting

In the following section, you will learn basic troubleshooting techniques for a secure Fortinet wireless LAN including:

- strategies for troubleshooting Fortinet wireless devices
- how to avoid common misconfigurations
- solutions to connectivity issues
- capturing and analyzing wireless traffic
- wireless debug commands

The goal of this document is to provide you with practical knowledge that you can use to troubleshoot the FortiOS wireless controller and FortiAP devices. This includes how to use tools and apply CLI commands for maintenance and troubleshooting of your wireless network infrastructure, analyze problems per OSI layer, explore diagnostics for commissioning issues regarding at-client and access point connectivity problems, and understand the packet sniffer technique as a strong troubleshooting tool.

The content is divided as follows:

FortiAP shell command through CAPWAP control tunnel

Very often, the FortiAP in the field is behind a NAT device, and access to the FortiAP through Telnet or SSH is not available. As a troubleshooting enhancement, this feature allows an AP shell command up to 127-bytes sent to the FAP, and FAP will run this command, and return the results to the controller using the CAPWAP tunnel.

The maximum output from a command is limited to 4M, and the default output size is set to 32K.

The FortiAP will only report running results to the controller after the command is finished. If a new command is sent to the AP before the previous command is finished, the previous command will be canceled.

Enter the following:

```
diag w-c wlap wtpcmd wtp_ip wtp_port cmd [cmd-to-ap] cmd: run,show,showhex,clr,r&h,r&sh
```

- **cmd-to-ap:** any shell commands, but AP will not report results until the command is finished on the AP
- **run:** controller sends the ap-cmd to the FAP to run
- **show:** show current results reported by the AP in text
- **showhex:** show current results reported by the AP in hex
- **clr:** clear reported results
- **r&s:** run/show
- **r&sh:** run/showhex

Signal strength issues

Poor signal strength is possibly the most common customer complaint. Below you will learn where to begin identifying and troubleshooting poor signal strength, and learn what information you can obtain from the customer to help resolve signal strength issues.

Asymmetric power issue

Asymmetric power issues are a typical problem. Wireless is two-way communication; high power access points (APs) can usually transmit a long distance, however, the client's ability to transmit is usually not equal to that of the AP and, as such, cannot return transmission if the distance is too far.

Measuring signal strength in both directions

To solve an asymmetric power issue, measure the signal strength in both directions. APs usually have enough power to transmit long distances, but sometimes battery-powered clients have a reply signal that has less power, and therefore the AP cannot detect their signal.

It is recommended that you match the transmission power of the AP to the least powerful wireless client—around 10 decibels per milliwatt (dBm) for iPhones and 14dBm for most laptops.

Even if the signal is strong enough, other devices may be emitting radiation as well, causing interference. To identify the difference, read the client Rx strength from the FortiGate GUI (under **Monitor > WiFi Client Monitor**) or CLI.

The **Signal Strength/Noise** value provides the received signal strength indicator (RSSI) of the wireless client. For example, A value of -85dBm to -95dBm is equal to about 10dB levels; this is not a desirable signal strength. In the following screenshot, one of the clients is at 18dB, which is getting close to the perimeter of its range.

SSID	FortiAP	IP	Device	Channel	Bandwidth Tx/Rx	Signal Strength/Noise	Signal
MavisF	FAP28C3X13000119 (1)	10.0.2.8	e8:91:20:90:6e:23	6	1 kbps	29 dB	<div><div></div></div>
MavisF	FP320C3X14000668 (1)	192.168.255.112	1c:69:a5:c8:e8:3e	11	80 bps	35 dB	<div><div></div></div>
MavisF	FP320C3X14000668 (2)	192.168.255.101	58:55:ca:36:28:7d	44	12 kbps	51 dB	<div><div></div></div>
MavisF	FAP28C3X13000119 (1)	10.0.2.9	Acer A1-830 Tablet	6	543 bps	18 dB	<div><div></div></div>
MavisF	FAP28C3X13000119 (1)	10.0.2.13	08:ed:b9:4f:98:ad	6	16 kbps	31 dB	<div><div></div></div>
MavisF	FP320C3X14000668 (1)	192.168.255.115	Ellas_Tablet	11	0 bps	35 dB	<div><div></div></div>

The Signal Strength/Noise value received from the FortiAP by clients, and vice versa, should be within the range of -20dBm to -65dBm.

You can also confirm the transmission (Tx) power of the controller on the AP profile (`wtp-profile`) and the FortiAP (`iwconfig`), and check the power management (auto-Tx) options.

Controller configured transmitting power - CLI:

```
config wireless-controller wtp-profile
config <radio>
show
```

(the following output is limited to power levels)

```
auto-power-level : enable
auto-power-high : 17
auto-power-low : 10
```

Actual FortiAP transmitting power - CLI:

```
iwconfig wlan00
```

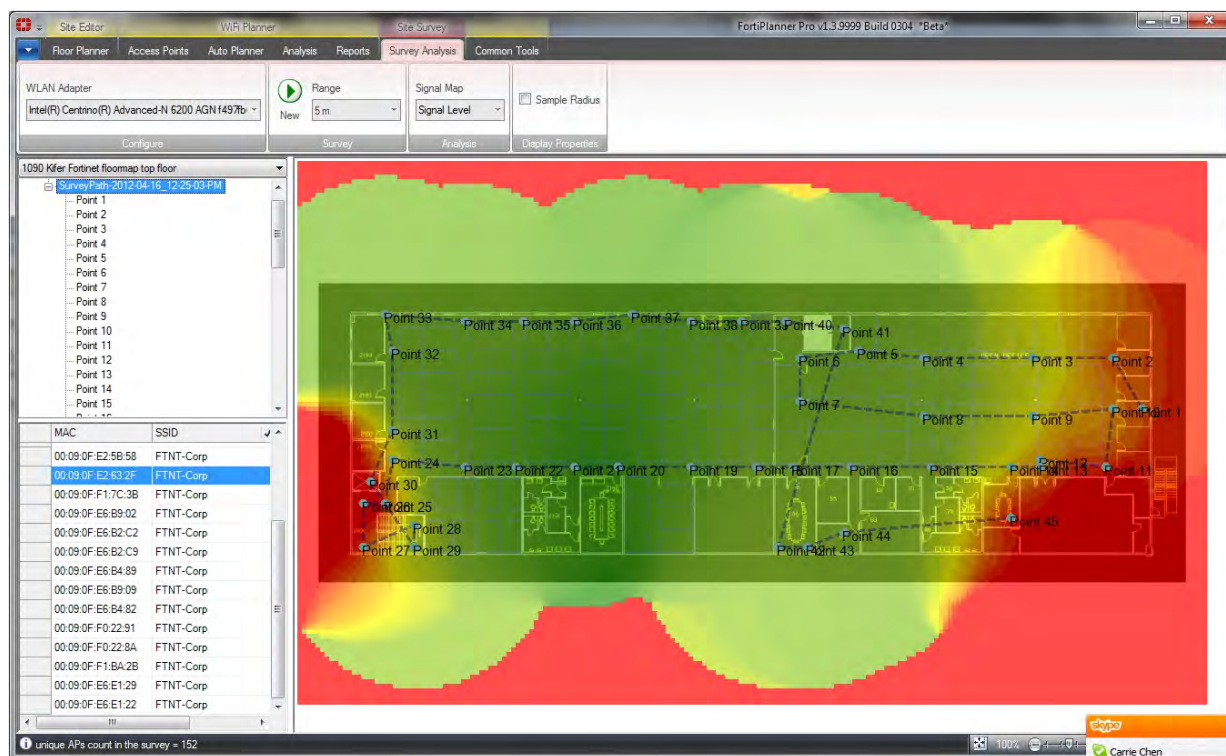

Result:

```
wlan00 IEEE 802.11ng ESSID:"signal-check"
Mode:Master Frequency:2.412 GHz Access Point:<MAC add>
Bit Rate:130 Mb/s Tx-Power=28 dBm
```

Using FortiPlanner PRO with a site survey

The most thorough method to solve signal strength issues is to perform a site survey. To this end, Fortinet offers the FortiPlanner, downloadable at http://www.fortinet.com/resource_center/product_downloads.html.

Sample depiction of a site survey using FortiPlanner

The site survey provides you with optimal placement for your APs based on the variables in your environment. You must provide the site survey detailed information including a floor plan (to scale), structural materials, and more. It will allow you to place the APs on the map and adjust the radio bands and power levels while providing you with visual wireless coverage.

Below is a list of mechanisms for gathering further information on the client for Rx strength. The goal is to see how well the client is receiving the signal from the AP. You can also verify FortiAP signal strength on the client

using WiFi client utilities, or third party utilities such as InSSIDer or MetaGeek Chanalyzer. You can get similar tools from the app stores on Android and iOS devices.

- Professional Site Survey software (Ekahau, Airmagnet survey Pro, FortiPlanner)
- InSSIDer
- On Windows: “*netsh wlan show networks mode=bssid*” (look for the BSSID, it's in % not in dBm!)
- On MacOS: Use the “*airport*” command:

```
"/System/Library/PrivateFrameworks/Apple80211.framework/Versions/A/Resources/airport" airport -s | grep <the_bssid>
```

 (live scan each time)
- On Droid: WiFiFoFum

Frequency interference

If the wireless signal seems to be strong but then periodically drops, this may be a symptom of frequency interference. Frequency interference is when another device also emits radio frequency using the same channel, co-channel, or adjacent channel, thereby overpowering or corrupting your signal. This is a common problem on a 2.4GHz network.

There are two types of interference: coherent and non-coherent.

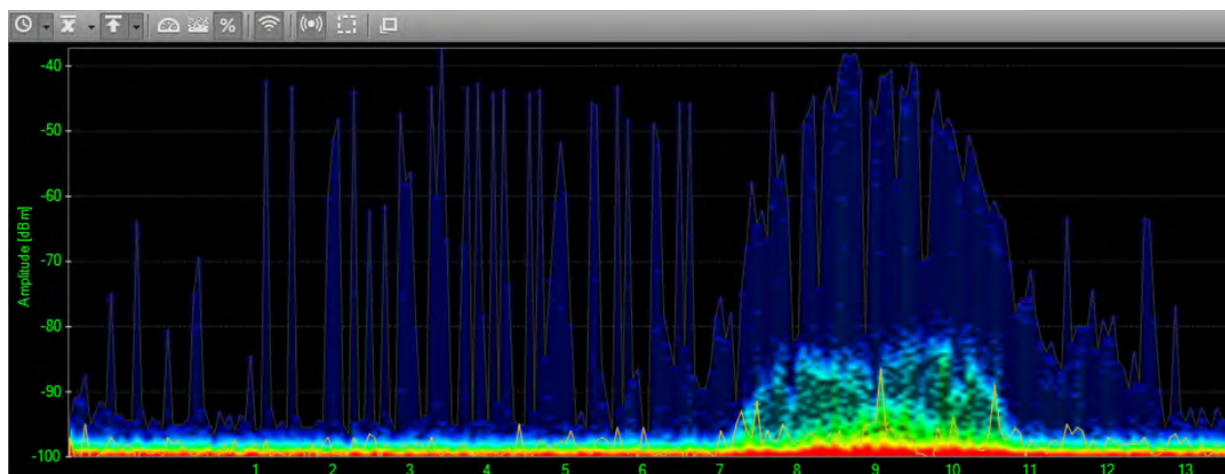

- **Coherent interference:** a result of another device using the same channel as your AP, or poor planning of a wireless infrastructure (perhaps the other nearby APs are using the same channel or the signal strength is too high).
- **Non-coherent interference:** a result of other radio signals such as bluetooth, microwave, cordless phone, or (as in medical environments) x-ray machines.

Most common and simple solution for frequency interference is to change your operation channel. Typically, the channel can be set from 1 to 11 for the broadcast frequency, although you should always use channels 1, 6, and 11 on the 2.4GHz band.

Another solution, if it's appropriate for your location, is to use the 5GHz band instead.

MetaGeek Chanalyzer

You can perform a site survey using spectrum analysis at various points in your environment looking for signal versus interference/noise. MetaGeek Chanalyzer is an example of a third party utility which shows a noise threshold.

Note that a signal of -95dBm or less will be ignored by Fortinet wireless adapters.

Throughput issues

Sometimes communication issues can be caused by low performance.

Testing the link

You can identify delays or lost packets by sending ping packets from your wireless client. If there is more than 10ms of delay, there may be a problem with your wireless deployment, such as:

- a weak transmit signal from the client (the host does not reach the AP)
- the AP utilization is too high (your AP could be saturated with connected clients)
- interference (third party signal could degrade your AP or client's ability to detect signals between them)
- weak transmit power from the AP (the AP does not reach the host) -- not common in a properly deployed network, unless the client is too far away

Keep in mind that water will also cause a reduction in radio signal strength for those making use out of outdoor APs or wireless on a boat.

Performance testing

If the FortiAP gives bad throughput to the client, the link may drop. The throughput or performance can be measured on your smartphone with third party applications tool such as iPerf and jPerf.

Measuring file transfer speed

Another way to get a sense of your throughput issues is to measure the speed of a file transfer on your network. Create a test file at a specific size and measure the speed at which Windows measures the transfer. The command below will create a 50MB file.

- `fsutil file createnew test.txt 52428800`

The following image shows a network transfer speed of just over 24Mbps. The theoretical speed of 802.11g is 54Mbps, which is what this client is using. A wireless client is never likely to see the theoretical speed.

TKIP limitation

If you find that throughput is a problem, avoid WPA security encrypted with Temporal Key Integrity Protocol (TKIP) as it supports communications only at 54Mbps. Use WPA-2 AES instead.

Speeds are very much based on what the client computer can handle as well. The maximum client connection rate of 130Mbps is for 2.4GHz on a 2x2, or 300Mbps for 5Ghz on a 2x2 (using shortguard and channel bonding enabled).

If you want to get more than 54Mbps with 802.11n, do not use legacy TKIP, use CCMP instead. This is standard for legacy compatibility.

Preventing IP fragmentation in CAPWAP

TKIP is not the only possible source of decreased throughput. When a wireless client sends jumbo frames using a CAPWAP tunnel, it can result in data loss, jitter, and decreased throughput.

Using the following commands you can customize the uplink rates and downlink rates in the CAPWAP tunnel to prevent fragmentation and avoid data loss.

```
config wireless-controller wtp
  edit new-wtp
    set ip-fragment-preventing [tcp-mss-adjust | icmp-unreachable]
    set tun-mtu-uplink [0 | 576 | 1500]
    set tun-mtu-downlink [0 | 576 | 1500]
  end
end
```

The default value is 0, however the recommended value will depend on the type of traffic. For example, IPsec in tunnel mode has 52 bytes of overhead, so you might use 1400 or less for uplink and downlink.

Slowness in the DTLS response

It's important to know all the elements involved in the CAPWAP association:

- Request
- Response
- DTLS
- Join
- Configuration

All of these are bidirectional. So if the DTLS response is slow, this might be the result of a configuration error. This issue can also be caused by a certificate during discovery response. You can read more about this in [RFC 5416](#).

Connection issues

If the client has a connectivity issue that is not due to signal strength, the solution varies by the symptom.

Client connection issues

1. If client is unable to connect to FortiAP:
 - Make sure the client's security and authentication settings match with FortiAP and check the certificates as well.

- Try upgrading the Wi-Fi adapter driver and FortiGate/FortiAP firmware.
 - If other clients can connect, it could be interoperability; run debug commands and sniffer packets.
 - Look for rogue suppression by sniffing the wireless traffic and looking for the disconnect in the output (using the AP or wireless packet sniffer).
 - Try changing the IEEE protocol from 802.11n to 802.11bg or 802.11a only.
2. If the client drops and reconnects:
 - The client might be de-authenticating periodically. Check the sleep mode on the client.
 - The issue could be related to power-saver settings. The client may need to update drivers.
 - The issue could also be caused by flapping between APs. Check the roaming sensitivity settings on the client or the preferred wireless network settings on the client—if another WiFi network is available, the client may connect to it if it is a preferred network. Also, check the DHCP configuration as it may be an IP conflict.
 3. If the client drops and never connects:
 - It could have roamed to another SSID, so check the standby and sleep modes.
 - You may need to bring the interface up and down.
 4. If the client connects, but no IP address is acquired by the client:
 - Check the DHCP configuration and the network.
 - It could be a broadcast issue, so check the WEP encryption key and set a static IP address and VLANs.

Debug

You should also enable client debug on the controller for problematic clients to see the stage at which the client fails to connect. Try to connect from the problematic client and run the following debug command, which allows you to see the four-way handshake of the client association:

```
diagnose wireless-controller wlac sta_filter <client MAC address> 2
```

Example of a successful client connection:

The following is a sample debug output for the above command, with successful association/DHCP phases and PSK key exchange (identified in color):

```

where:

- **orange** represents the association phase,
- **blue** represents the PSK exchange,
- and **green** represents the DHCP phase.

It is important to note the messages for a correct association phase, four-way handshake, and DHCP phase.

Checking WiFi password

Admins can view plain text passwords (captive-portal-radius-secret and passphrase) under config wireless-controller vap.

Note that security must be set as a WPA-personal setting.

FortiAP connection issues

Clients are not the only device that can fail to connect, of course. A communication problem could arise from the FortiAP.

Some examples include:

- The FortiAP is not connecting to the wireless controller.
- One FortiAP intermittently disconnects and re-connects.
- All FortiAPs intermittently disconnect and re-connect.
- Unable to Telnet to FortiAP from controller/administrator workstation.

In the above cases:

- Check networking on the distribution system for all related FortiAPs.
- Check the authorization status of managed APs from the wireless controller.
- Restart the `cw_acd` process (**Note:** All APs will drop if you do this, and you may be troubleshooting just one AP).
- Check the controller crash log for any wireless controller daemon crash using the following command:

```
diagnose debug crashlog read
```

Debug

For a quick assessment of the association communication between the controller and the FortiAP, run the following sniffer command to see if you can verify that the AP is communicating to the controller by identifying the CAPWAP communication:

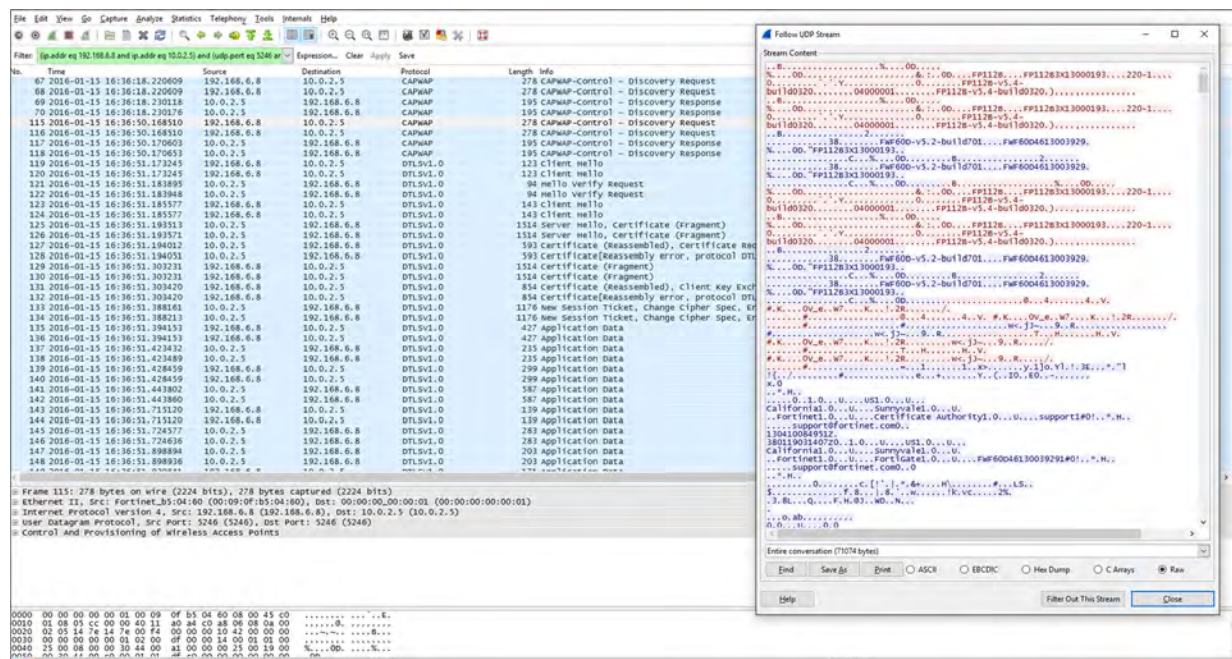

```
diagnose sniff packet <interface_name> "port 5246" 4
```

If you do not see this communication, then you can investigate the network or the settings on the AP to see why it is not reaching the controller.

The following command allows you to collect verbose output from the sniff that can be converted to a PCAP and viewed in Wireshark.

```
diagnose sniff packet <interface_name> "port 5246" 6 o 1
```

The image below shows the beginning of the AP's association to the controller. You can see the discovery Request and Response at the top.

Throughout debugging it is recommended to:

- Enable Telnet login to the FortiAP device so that you can log in and issue local debugging commands:

```
config wireless-controller wtp
edit "<FortiAP_serial_number>"
set override-allowaccess {disable|enable}
set allowaccess {telnet | http | https | ssh}
end
```

- Try to connect to the wireless controller from the problematic FortiAP to verify routes exist.
- Enable wtp (FortiAP) debugging on the wireless controller for problematic FortiAPs to determine the point at which the FortiAP fails to connect:

```
diag wireless-controller wlap wtp_filter FP112B3X13000193 0-192.168.6.8:5246 2
(replace the serial number and IP address of the FortiAP)
```

```
di de console timestamp en
di de application cw_acd 0x7ff
di de en
```

Example of a successful AP and controller association:

The previous debug command provides similar output to the sample debug message below for a successful association between the FortiAP and the wireless controller. This includes the elements of the CAPWAP protocol; the Request, Response, DTLS, Join, and Configuration (identified in color). All of these are bi-directional, so if the DTLS response is slow, it may be an example of a configuration error.

where:

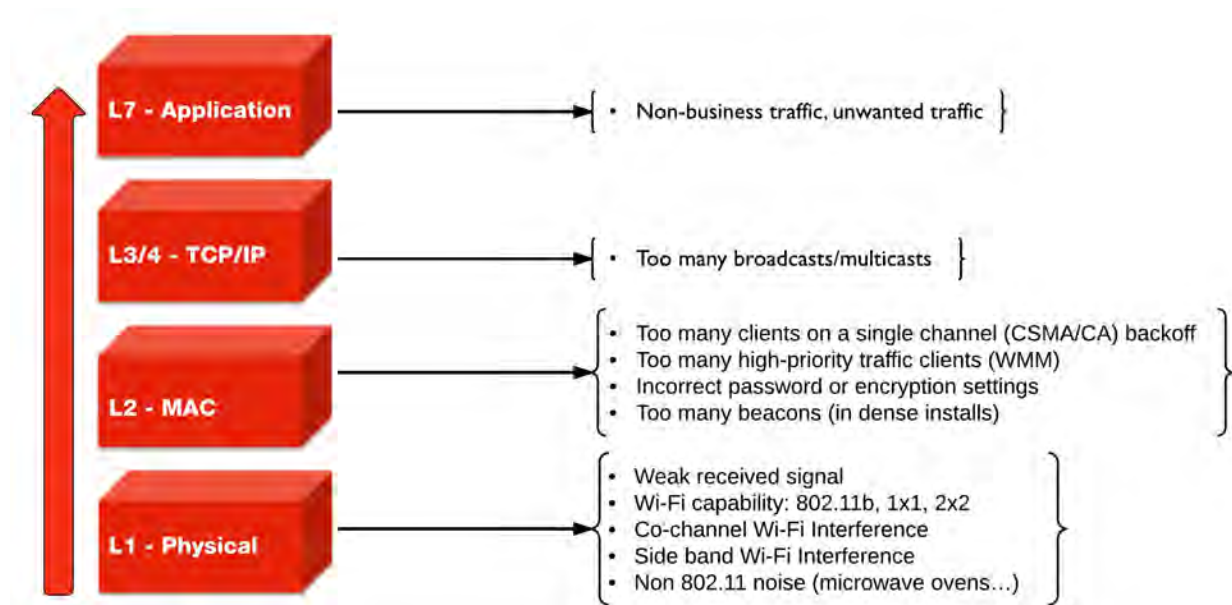

- **orange** represents the Discovery phase,
- **blue** indicates that the control channels have been established using DTLS,
- **green** represents the access point Discovery and Join phase,
- **purple** represents the Clear Text channel,
- and **pink** indicates that the FortiAP successfully connected to the wireless controller.

General problems

Not all WiFi problems are related to signal strength, interference, or misconfiguration. The following OSI model identifies some of the more common issues per layer.

Best practices for troubleshooting vary depending on the affected layer (see below).

Common sources of wireless issues

Best practices for Layer 1

Common physical layer issues include:

- Weak received signal,
- WiFi capability: 802.11b, 1x1, 2x2,
- Co-channel WiFi interference,
- Side band WiFi interference,
- Non 802.11 noise (microwave ovens...).

To avoid physical layer issues:

- Determine RST (Receiver Sensitivity Threshold) for your device, or use -70dBm as a rule of thumb.
- Match AP TX output power to the client TX output power.
 - Note:** iPhone TX power is only 10dBm.
- Use DFS (Dynamic Frequency Selection) for high performance data 20/40 MHz.
- Use 5GHz UNII-1 & 3 (Non-DFS) bands with static channel assignment for latency-sensitive applications.
- Do not use 40MHz channels in 2.4 GHz band (channel bonding is not allowed in FortiOS).

Best practices for Layer 2

Common data link (MAC) layer issues include:

- Too many clients on a single channel (CSMA/CA) backoff,
- Too many high-priority traffic clients (WMM),
- Incorrect password or encryption settings,
- Too many beacons (in dense installs).

To avoid data link layer issues:

- Only use CCMP/AES (WPA2) encryption (not TKIP).
- In high density deployments, turn off SSID broadcast or turn down SSID rates. Review and possibly reduce the beacon interval.
- Determine the best cell size for applications:
 - For few users and low bandwidth latency sensitive applications, use high transmit power to create larger cells.
 - For high performance/high capacity installations, use lower transmit power to create smaller cells (set FortiPlanner at 10dBm TX power), but bear in mind that this will require more roaming.

Cells and co-channel interference

In high density deployments, multiple APs are used, and each one services an area called a cell. However, these cells can cause interference with each other. This is a common problem. The radio signal from one AP interferes with, or cancels out, the radio signal from another AP.

In the following diagram, note the interference zone created by one radio, causing interference on its neighbouring APs.

The interference zone can be twice the radius of the signal, and the signal at its edge can be -67dBm.

Reducing co-channel interference

For best results, use a 'honeycomb' pattern as a deployment strategy. The idea is to *stagger* repeated channels furthest from each other to avoid interference.

Best practices for Layer 3 and above

For TCP/IP layers and above, a common source of latency, or slowness in the wireless traffic, is too many broadcasts or multicasts. These types of issues can result from non-business and/or unwanted traffic.

To resolve issues at the TCP/IP layer and above:

- Identify business-critical applications.
- Use Application Control, Web Filtering, Traffic Shaping, and QoS to prioritize applications.
 - Identify unwanted traffic, high-bandwidth web-related traffic, and use Security Profiles.
 - Use the traffic shaper on a policy to rate-limit this traffic.

These configurations are performed directly on the FortiGate.

Packet sniffer

Capturing the traffic between the controller and the FortiAP can help you identify most FortiAP and client connection issues.

This section describes the following recommended packet sniffing techniques:

- [CAPWAP packet sniffer](#)
- [Wireless traffic packet sniffer](#)

CAPWAP packet sniffer

The first recommended technique consists of sniffing the CAPWAP traffic.

- Enable plain control on the controller and on the FortiAP to capture clear control traffic on UDP port 5246.
 - On the controller:

```
diagnose wireless-controller wlac plain-ctl <FortiAP_serial_number> 1
```

Result:

```
WTP 0-FortiAP2223X11000107 Plain Control: enabled
```

- On the FortiAP:

```
cw_diag plain-ctl 1
```

Result:

```
Current Plain Control: enabled
```

Note that some issues are related to the keep-alive for control and data channel.

- Data traffic on UDP port 5247 is not encrypted. The data itself is encrypted by the wireless security mechanism.

Data traffic is helpful to troubleshoot most of the issues related to station association, EAP authentication, WPA key exchange, roaming, and FortiAP configuration.

You can also set up a host or server to which you can forward the CAPWAP traffic:

1. Configure the host/server to which CAPWAP traffic is forwarded:

```
diagnose wireless-controller wlac sniff-cfg <Host_IP_address> 88888
```

Result:

```
Current Sniff Server: 192.168.25.41, 23352
```

2. Choose which traffic to capture, the interface to which the FortiAP is connected, and the FortiAP's serial number:

```
diagnose wireless-controller wlac sniff <interface_name> <FortiAP_serial_number> 2
```

Result:

```
WTP 0-FortiAP2223X11000107 Sniff: intf port2 enabled (control and data message)
```

In the above syntax, the '2' captures the control and data message—'1' would capture only the control message, and '0' would disable it.

3. Run Wireshark on the host/server to capture CAPWAP traffic from the controller.
 - Decode the traffic as IP to check inner CAPWAP traffic.

Example CAPWAP packet capture

The following image shows an example of a CAPWAP packet capture, where you can see: the Layer 2 header; the sniffed traffic encapsulated into Internet Protocol for transport; CAPWAP encapsulated into UDP for sniffer purpose and encapsulated into IP; CAPWAP control traffic on UDP port 5246; and CAPWAP payload.

No.	Time	Source	Destination	Protocol	Info
1	0.000000	192.168.35.82	192.168.35.80	CAPWAP	Control Msg - Echo Request
2	0.000308	192.168.35.82	192.168.35.80	CAPWAP	Control Msg - Echo Request
3	0.000452	192.168.35.80	192.168.35.82	CAPWAP	Control Msg - Echo Response
4	0.000454	192.168.35.80	192.168.35.82	CAPWAP	Control Msg - Echo Response

Wireless traffic packet sniffer

The second recommended technique consists of sniffing the wireless traffic directly 'on the air' using your FortiAP.

Wireless traffic packet capture

Packet captures are useful for troubleshooting all wireless client related issues because you can verify data rate and 802.11 parameters, such as radio capabilities, and determine issues with wireless signal strength, interference, or congestion on the network.

A radio can only capture one frequency at a time; one of the radios is set to sniffer mode depending on the traffic or channel required. You must use two FortiAPs to capture both frequencies at the same time.

- Set a radio on the FortiAP to monitor mode.

```
iwconfig wlan10
```

Result:

```
wlan10 IEEE 802.11na ESSID:""
Mode:Monitor Frequency:5.18 GHz Access Point: Not-Associated
```

- The capture file is stored under the temp directory as *wl_sniff.pcap*

```
/tmp/wl_sniff.pcap
```

- Remember that the capture file is only stored temporarily. If you want to save it, upload it to a TFTP server before rebooting or changing the radio settings.
- The command `cp wl_sniff.pcap newname.pcap` allows you to rename the file.

- Rather than TFTP the file, you can also log in to the AP and retrieve the file via the web interface. Move the file using the command: `mv name /usr/www`

You can verify the file was moved using the command `cd/usr/www` and then browsing to: `<fortiAP_IP>/filename`

Syntax

The following syntax demonstrates how to set the radio to sniffer mode (configurable from the CLI only). Sniffer mode provides options to filter for specific traffic to capture. Notice that you can determine the buffer size, which channel to sniff, the AP's MAC address, and select if you want to sniff the beacons, probes, controls, and data channels.

```
configure wireless-controller wtp-profile
  edit <profile_name>
    configure <radio>
      set mode sniffer
      set ap-sniffer-bufsize 32
      set ap-sniffer-chan 1
      set ap-sniffer-addr 00:00:00:00:00:00
      set ap-sniffer-mgmt-beacon enable
      set ap-sniffer-mgmt-probe enable
      set ap-sniffer-mgmt-other enable
      set ap-sniffer-ctl enable
      set ap-sniffer-data enable
    end
  end
```

Once you've performed the previous CLI configuration, you'll be able to see the packet sniffer mode selected in the GUI dashboard under **WiFi & Switch Controller > FortiAP Profiles** and **WiFi & Switch Controller > Managed FortiAPs**. Bear in mind that if you change the mode from the GUI, you'll have to return to the CLI to re-enable the Sniffer mode.

To disable the sniffer profile in the CLI, use the following commands:

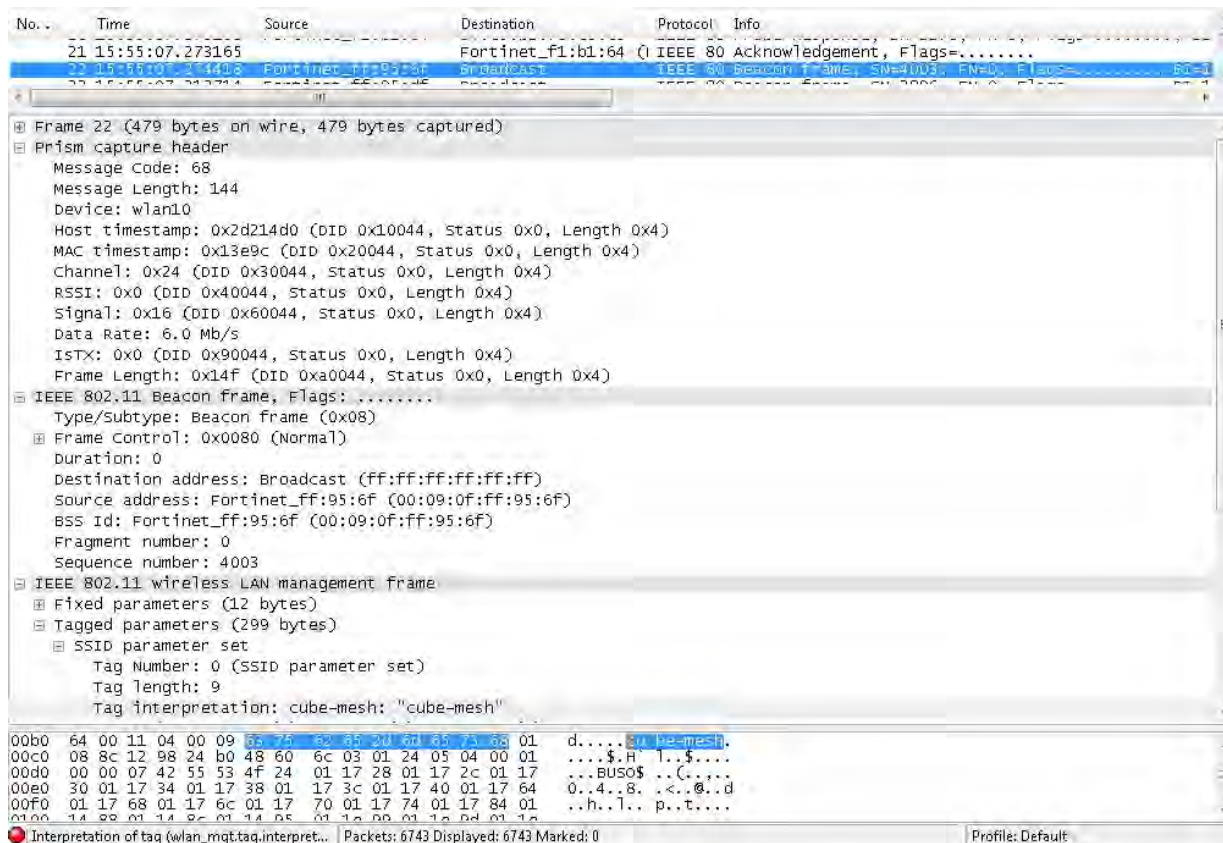

```
config wireless-controller wtp-profile
  edit <profile_name>
    config <radio>
      set ap-sniffer-mgmt-beacon disable
      set ap-sniffer-mgmt-probe disable
      set ap-sniffer-mgmt-other disable
      set ap-sniffer-ctl disable
      set ap-sniffer-data disable
    end
  end
```

If you change the radio mode before sending the file *wl_sniff.cap* to an external TFTP, the file will be deleted and you will lose your packet capture.

Example AP packet capture

The following image shows an example of the AP packet capture. Note the capture header showing channel 36; the beacon frame; the source, destination, and BSSID of the beacon frame; and the SSID of the beacon frame.

Useful debugging commands

For a comprehensive list of useful debug options you can use the following help commands on the controller:

```
diagnose wireless-controller wlac help
(this command lists the options available that pertain to the wireless controller)
```

```
diagnose wireless-controller wlwtp help
(this command lists the options available that pertain to the AP)
```

Sample outputs

Syntax

```
diagnose wireless-controller wlac -c vap
(this command lists the information about the virtual access point, including its MAC address, the BSSID, its SSID, the interface name, and the IP address of the APs that are broadcasting it)
```

Result:

```
bssid      ssid      intf      vfid:ip-port  rId  wId
00:09:0f:d6:cb:12 Office Office  ws (0-192.168.3.33:5246) 0 0
00:09:0f:e6:6b:12 Office Office  ws (0-192.168.1.61:5246) 0 0
06:0e:8e:27:dc:48 Office Office  ws (0-192.168.3.36:5246) 0 0
0a:09:0f:d6:cb:12 public publicAP ws (0-192.168.3.33:5246) 0 1
```

Syntax

```
diagnose wireless-controller wlac -c darrp
```

(this command lists the information pertaining to the radio resource provisioning statistics, including the AP serial number, the number of channels set to choose from, and the operation channel. Note that the 5GHz band is not available on these APs listed)

Result:

wtp_id	rId	base_mac	index	nr_chan	vfid	5G	oper_chan	age
FAP22A3U10600400	0	00:09:0f:d6:cb:12	0	3	0	No	1	87588

Reference

This chapter provides some reference information pertaining to wireless networks.

FortiAP web-based manager

You can access the FortiAP unit's built-in web-based manager. This is useful to adjust settings that are not available through the FortiGate unit's WiFi Controller. Logging into the FortiAP web-based manager is similar to logging into the FortiGate web-based manager.

System Information

Status

The **Status** section provides information about the FortiAP unit.

Host Name	FAP22B3U11005354 [Change]
Serial Number	FAP22B3U11005354
Region Code	A
Firmware Version	FortiAP-220B v5.0,build064,140117 (GA) [Update]
Network Status	0.0.0.0/0.0.0.0/0.0.0.0 (Mon Jun 2 12:50:05 2014)
System Time	Tue May 27 13:00:39 2014
Current Administrator	admin [Change Password]
System Configuration	Last Backup: N/A [Backup] [Restore]
Uptime	7 day(s) 2 hour(s) 4 min(s)
CPU Usage	<div><div></div></div> 1%
Memory Usage	<div><div></div></div> 35%
AC Discovery Status	Discovering AC ...

You can:

- Select **Change** to change the **Host Name**.
- Select **Update** in **Firmware Version** to upload a new FortiAP firmware file from your computer.
- Select **Change Password** to change the administrator password.
- Select **Backup** to save the current FortiAP configuration as a file on your computer.
- Select **Restore** to load a configuration into your FortiAP unit from a file on your computer.

Network Configuration

Select DHCP or select Static and specify the IP address, netmask, and gateway IP address. **Administrative Access** settings affect access after the FortiAP has been authorized. By default, **HTTP** access needed to access the FortiAP web-based manager is enabled, but **Telnet** access is not enabled.

Connectivity

These settings determine how the FortiAP unit connects to the FortiGate WiFi controller.

Uplink	Ethernet - wired connection to the FortiGate unit (default) Mesh - WiFi mesh connection Ethernet with mesh backup support
Mesh AP SSID	Enter the SSID of the mesh root. Default: fortinet.mesh.root
Mesh AP Password	Enter password for the mesh SSID.
Ethernet Bridge	Bridge the mesh SSID to the FortiAP Ethernet port. This is available only when Uplink is Mesh .

WTP Configuration

AC Discovery Type settings affect how the FortiAP unit discovers a FortiGate WiFi controller. By default, this is set to Auto which causes the FortiAP unit to cycle through all of the discovery methods until successful. For more information see Controller discovery methods.

AC Discovery Type	Static, DHCP, DNS, Broadcast, Multicast, Auto
AC Control Port	Default port is 5246.
AC IP Address 1 AC IP Address 2 AC IP Address 3	You enter up to three WiFi controller IP addresses for static discovery. Routing must be properly configured in both directions.
AC Host Name 1 AC Host Name 2 AC Host Name 3	As an alternative to AC IP addresses, you can enter their fully qualified domain names (FQDNs).
AC Discovery Multicast Address	224.0.1.140
AC Discovery DHCP Option Code	When using DHCP discovery, you can configure the DHCP server to provide the controller address. By default the FortiAP unit expects this in option 138.

AC Data Channel Security by default accepts either DTLS-encrypted or clear text data communication with the WiFi controller. You can change this setting to require encryption or to use clear text only.

Wireless Information

The Wireless Information page provides current information about the operation of the radios and the type Uplink in use.

Wireless radio channels

IEEE 802.11a/n channels

The following table lists the channels supported on FortiWiFi products that support the IEEE 802.11a and 802.11n wireless standards. 802.11a is available on FortiWiFi models 60B and higher. 802.11n is available on FortiWiFi models 80CM and higher.

All channels are restricted to indoor usage except in the Americas, where both indoor and outdoor use is permitted on channels 52 through 64 in the United States.

IEEE 802.11a/n (5-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas				
		Americas	Europe	Taiwan	Singapore	Japan
34	5170					•
36	5180	•	•		•	
38	5190					
40	5200	•	•		•	•
42	5210					
44	5220	•	•		•	•
46	5230					
48	5240	•	•		•	•
149	5745	•		•	•	
153	5765	•		•	•	
157	5785	•		•	•	
161	5805	•		•	•	
165	5825	•			•	

IEEE 802.11b/g/n channel numbers

The following table lists IEEE 802.11b/g/n channels. All FortiWiFi units support 802.11b and 802.11g. Newer models also support 802.11n.

Mexico is included in the Americas regulatory domain. Channels 1 through 8 are for indoor use only. Channels 9 through 11 can be used indoors and outdoors. You must make sure that the channel number complies with the regulatory standards of Mexico.

IEEE 802.11b/g/n (2.4-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas			
		Americas	EMEA	Israel	Japan
1	2412	•	•	indoor	•
2	2417	•	•	indoor	•
3	2422	•	•	indoor	•
4	2427	•	•	indoor	•
5	2432	•	•	•	•

View all Country & Regcodes/Regulatory Domains

The following CLI command can be entered to view a list of the Country & Regcodes/Regulatory Domains supported by Fortinet:

```
cw_diag -c all-countries
```

Below is a table showing a sample of the list displayed by entering this command:

Country-code	Region-code	Domain	ISO-name	Name
0	A	FCC3 & FCCA	NA	NO_COUNTRY_SET

Country-code	Region-code	Domain	ISO-name	Name
8	W	NULL1 & WORLD	AL	ALBANIA
12	W	NULL1 & WORLD	DZ	ALGERIA
16	A	FCC3 & FCCA	AS	AMERICAN SAMOA
...

WiFi event types

Event type	Description
rogue-ap-detected	A rogue AP has been detected (generic).
rogue-ap-off-air	A rogue AP is no longer detected on the RF side.
rogue-ap-on-wire	A rogue AP has been detected on wire side (connected to AP or controller L2 network).
rogue-ap-off-wire	A rogue AP is no longer detected on wire.
rogue-ap-on-air	A rogue AP has been detected on the RF side.
fake-ap-detected	A rogue AP broadcasting on the same SSIDs that you have in your managed APs has been detected.
fake-ap-on-air	The above fake AP was detected on the RF side.

FortiAP CLI

The FortiAP CLI controls radio and network operation through the use of variables manipulated with the `cfg` command. There are also diagnostic commands.

The `cfg` command include the following

<code>cfg -s</code>	List variables.
<code>cfg -a var=value</code>	Add or change a variable value.
<code>cfg -c</code>	Commit the change to flash.
<code>cfg -x</code>	Reset settings to factory defaults.
<code>cfg -r var</code>	Remove variable.

<code>cfg -e</code>	Export variables.
<code>cfg -h</code>	Display help for all commands.

The configuration variables are:

Var	Description and Values
<code>AC_CTL_PORT</code>	WiFi Controller control (CAPWAP) port. Default 5246.
<code>AC_DATA_CHAN_SEC</code>	Data channel security. 0 - Clear text 1 - DTLS (encrypted) 2 - Accept either DTLS or clear text (default)
<code>AC_DISCOVERY_TYPE</code>	1 - Static. Specify WiFi Controllers 2 - DHCP 3 - DNS 5 - Broadcast 6 - Multicast 0 - Cycle through all of the discovery types until successful.
<code>AP_IPADDR</code> <code>AP_NETMASK</code> <code>IPGW</code>	These variables set the FortiAP unit IP address, netmask and default gateway when ADDR_MODE is STATIC. Default 192.168.1.2 255.255.255.0, gateway 192.168.1.1.
<code>AC_HOSTNAME_1</code> <code>AC_HOSTNAME_2</code> <code>AC_HOSTNAME_3</code>	WiFi Controller host names for static discovery.
<code>AC_IPADDR_1</code> <code>AC_IPADDR_2</code> <code>AC_IPADDR_3</code>	WiFi Controller IP addresses for static discovery.
<code>AC_DISCOVERY_DHCP_OPTION_CODE</code>	Option code for DHCP server. Default 138.
<code>AC_DISCOVERY_MC_ADDR</code>	Multicast address for controller discovery. Default 224.0.1.140.

Var	Description and Values
ADDR_MODE	How the FortiAP unit obtains its IP address and netmask. DHCP - FortiGate interface assigns address. STATIC - Specify in AP_IPADDR and AP_NETMASK. Default is DHCP.
ADMIN_TIMEOUT	Administrative timeout in minutes. Applies to Telnet and web-based manager sessions. Default is 5 minutes.
AP_MGMT_VLAN_ID	Non-zero value applies VLAN ID for unit management. Default: 0.
AP_MODE	FortiAP operating mode. 0 - Thin AP (default) 2 - Unmanaged Site Survey mode. See SURVEY variables.
BAUD_RATE	Console data rate: 9600, 19200, 38400, 57600, or 115200 baud.
DNS_SERVER	DNS Server for clients. If ADDR_MODE is DHCP the DNS server is automatically assigned.
FIRMWARE_UPGRADE	Default is 0.
HTTP_ALLOW	Access to FortiAP web-based manager 1 - Yes (default), 0 - No.
LED_STATE	Enable/disable status LEDs. 0 - LEDs enabled, 1 - LEDs disabled, 2 - follow AC setting.
LOGIN_PASSWD	Administrator login password. By default this is empty.
STP_MODE	Spanning Tree Protocol. 0 is off. 1 is on.
TELNET_ALLOW	By default (value 0), Telnet access is closed when the FortiAP unit is authorized. Set value to 1 to keep Telnet always available.
WTP_LOCATION	Optional string describing AP location.
Mesh variables	

Var	Description and Values
MESH_AP_BGSCAN	Enable or disable background mesh root AP scan. 0 - Disabled 1 - Enabled
MESH_AP_BGSCAN_RSSI	If the root AP's signal is weak, and lower than the received signal strength indicator (RSSI) threshold, the WiFi driver will immediately start a new round scan and ignore the configured MESH_AP_BGSCAN_PERIOD delays. Set the value between 0-127. After the new round scan is finished, a scan done event is passed to wtp daemon to trigger roaming.
MESH_AP_BGSCAN_PERIOD	Time in seconds that a delay period occurs between scans. Set the value between 1-3600.
MESH_AP_BGSCAN_IDLE	Time in milliseconds. Set the value between 0-1000.
MESH_AP_BGSCAN_INTV	Time in milliseconds between channel scans. Set the value between 200-16000.
MESH_AP_BGSCAN_DUR	Time in milliseconds that the radio will continue scanning the channel. Set the value between 10-200.
MESH_AP_SCANCHANLIST	Specify those channels to be scanned.
MESH_AP_TYPE	Type of communication for backhaul to controller: 0 - Ethernet (default) 1 - WiFi mesh 2 - Ethernet with mesh backup support
MESH_AP_SSID	SSID for mesh backhaul. Default: fortinet.mesh.root
MESH_AP_BSSID	WiFi MAC address
MESH_AP_PASSWD	Pre-shared key for mesh backhaul.
MESH_ETH_BRIDGE	1 - Bridge mesh WiFi SSID to FortiAP Ethernet port. This can be used for point-to-point bridge configuration. This is available only when MESH_AP_TYPE =1. 0 - No WiFi-Ethernet bridge (default).

Var	Description and Values
MESH_MAX_HOPS	Maximum number of times packets can be passed from node to node on the mesh. Default is 4.
The following factors are summed and the FortiAP associates with the lowest scoring mesh AP.	
MESH_SCORE_HOP_WEIGHT	Multiplier for number of mesh hops from root. Default 50.
MESH_SCORE_CHAN_WEIGHT	AP total RSSI multiplier. Default 1.
MESH_SCORE_RATE_WEIGHT	Beacon data rate multiplier. Default 1.
MESH_SCORE_BAND_WEIGHT	Band weight (0 for 2.4GHz, 1 for 5GHz) multiplier. Default 100.
MESH_SCORE_RSSI_WEIGHT	AP channel RSSI multiplier. Default 100.
Survey variables	
SURVEY_SSID	SSID to broadcast in site survey mode (AP_MODE=2).
SURVEY_TX_POWER	Transmitter power in site survey mode (AP_MODE=2).
SURVEY_CH_24	Site survey transmit channel for the 2.4Ghz band (default 6).
SURVEY_CH_50	Site survey transmit channel for the 5Ghz band (default 36).
SURVEY_BEACON_INTV	Site survey beacon interval. Default 100msec.

Previously, FortiAP accepted Telnet and HTTP connection to any virtual interfaces that have an IP address. For security reasons, Telnet and HTTP access are now limited to br0 or br.vlan for AP_MGMT_VLAN_ID.

Diagnose commands include:

<code>cw_diag help</code>	Display help for all diagnose commands.
<code>cw_diag uptime</code>	Show daemon uptime.
<code>cw_diag --tlog <on off></code>	Turn on/off telnet log message.
<code>cw_diag --clog <on off></code>	Turn on/off console log message.
<code>cw_diag baudrate [9600 19200 38400 57600 115200]</code>	Set the console baud rate.

<code>cw_diag plain-ctl [0 1]</code>	Show or change current plain control setting.
<code>cw_diag sniff-cfg ip port</code>	Set sniff server ip and port.
<code>cw_diag sniff [0 1 2]</code>	Enable/disable sniff packet.
<code>cw_diag stats wl_intf</code>	Show wl_intf status.
<code>cw_diag admin-timeout [30]</code>	Set shell idle timeout in minutes.
<code>cw_diag -c wtp-cfg</code>	Show current wtp config parameters in control plane.
<code>cw_diag -c radio-cfg</code>	Show current radio config parameters in control plane.
<code>cw_diag -c vap-cfg</code>	Show current vaps in control plane.
<code>cw_diag -c ap-rogue</code>	Show rogue APs pushed by AC for on-wire scan.
<code>cw_diag -c sta-rogue</code>	Show rogue STAs pushed by AC for on-wire scan.
<code>cw_diag -c arp-req</code>	Show scanned arp requests.
<code>cw_diag -c ap-scan</code>	Show scanned APs.
<code>cw_diag -c sta-scan</code>	Show scanned STAs.
<code>cw_diag -c sta-cap</code>	Show scanned STA capabilities.
<code>cw_diag -c wids</code>	Show scanned WIDS detections.
<code>cw_diag -c darrp</code>	Show darrp radio channel.
<code>cw_diag -c mesh</code>	Show mesh status.
<code>cw_diag -c mesh-veth-acinfo</code>	Show mesh veth ac info, and mesh ether type.
<code>cw_diag -c mesh-veth-vap</code>	Show mesh veth vap.
<code>cw_diag -c mesh-veth-host</code>	Show mesh veth host.
<code>cw_diag -c mesh-ap</code>	Show mesh ap candidates.
<code>cw_diag -c scan-clr-all</code>	Flush all scanned AP/STA/ARPs.
<code>cw_diag -c ap-suppress</code>	Show suppressed APs.
<code>cw_diag -c sta-deauth</code>	De-authenticate an STA.

Link aggregation can also be set in the CLI. Link aggregation is used to combine multiple network connections in parallel in order to increase throughput beyond what a single connection could sustain.

- FortiAP 320B and 320C models are supported.
- FortiAP 112B and 112D models **cannot** support link aggregation.
- NPI FAP-S3xxCR and "wave2" FAP/FAP-S models will have link aggregation feature via synchronization with regular FortiAP trunk build.

Chapter 13 - Hardening

Hardening

This guide describes some of the techniques used to harden (improve the security of) FortiGate devices and FortiOS.

This document contains the following sections:

- [Building security into FortiOS](#)
- [FortiOS ports and protocols](#)
- [Security best practices](#)

Building security into FortiOS

The FortiOS operating system, FortiGate hardware devices, and FortiOS virtual machines (VMs) are built with security in mind, so many security features are built into the hardware and software. Fortinet maintains an ISO:9001 certified software and hardware development processes to ensure that FortiOS and FortiGate products are developed in a secure manner

Boot PROM and BIOS security

The boot PROM and BIOS in FortiGate hardware devices use Fortinet's own FortiBootLoader that is designed and controlled by Fortinet. FortiBootLoader is a secure, proprietary BIOS for all FortiGate appliances. FortiGate physical devices always boot from FortiBootLoader.

FortiOS kernel and user processes

FortiOS is a multi-process operating system with kernel and user processes. The FortiOS kernel runs in a privileged hardware mode while higher-level applications run in user mode. FortiOS is a closed system that does not allow the loading or execution of third-party code in the FortiOS user space. All non-essential services, packages, and applications are removed.

FortiGate appliances with SD drives are encrypted to prevent unauthorized access to data.

Administration access security

This section describes FortiOS and FortiGate administration access security features.

Admin administrator account

All FortiGate firewalls ship with a default administrator account called admin. By default, this account does not have a password. FortiOS allows administrators to add a password for this account or to remove the account and

create new custom super_admin administrator accounts.

For more information, see [Rename the admin administrator account on page 1578](#).

Secure password storage

User and administrator passwords are stored securely on the system in an encrypted format. The encryption hash used for admin account passwords is SHA256/SHA1. The value that is seen in the configuration file is the Base64 encoded hash value. For example:

```
config system admin
  edit "admin"
    set accprofile "super_admin"
    set vdom "root"
    set password ENC SH2nlSm9QL9tapcHPXIqAXvX7vBJuuqu22hpa0JX0sBuKIo7z2g0Kz/+0KyH4E=
  next
end
```

Pre-shared keys in IPSec phase-1 configurations are stored in plain text. In the configuration file these pre-shared keys are encoded. The encoding consists of encrypting the password with a fixed key using DES (AES in FIPS mode) and then Base64 encoding the result.

Maintainer account

Administrators with physical access to a FortiGate appliance can use a console cable and a special administrator account called maintainer to log into the CLI. When enabled, the maintainer account can be used to log in from the console after a hard reboot. The password for the maintainer account is bcpb followed by the FortiGate serial number. An administrator has 60-seconds to complete this login. See [Resetting a lost Admin password](#) on the Fortinet Cookbook for details.

The only action the maintainer account has permissions to perform is to reset the passwords of super_admin accounts. Logging in with the maintainer account requires rebooting the FortiGate. FortiOS generates event log messages when you login with the maintainer account and for each password reset.

The maintainer account is enabled by default; however, there is an option to disable this feature. The maintainer account can be disabled using the following command:

```
config system global
  set admin-maintainer disable
end
```

If you disable this feature and lose your administrator passwords you will no longer be able to log into your FortiGate.

Administrative access security

Secure administrative access features:

- SSH, Telnet, and SNMP are disabled by default. If required, these admin services must be explicitly enabled on each interface from the GUI or CLI.
- SSHv1 is disabled by default. SSHv2 is the default version.
- SSLv3 and TLS1.0 are disabled by default. TLSv1.1 and TLSv1.2 are the SSL versions enabled by default for HTTPS admin access.

- HTTP is disabled by default, except on dedicated MGMT, DMZ, and predefined LAN interfaces. HTTP redirect to HTTPS is enabled by default.
- The `strong-crypto` global setting is enabled by default and configures FortiOS to use strong ciphers (AES, 3DES) and digest (SHA1) for HTTPS/SSH/TLS/SSL functions.
- SCP is disabled by default. Enabling SCP allows downloading the configuration file from the FortiGate as an alternative method of backing up the configuration file. To enable SCP:

```
config system global
    set admin-scp enable
end
```

- DHCP is enabled by default on the dedicated MGMT interface and on the predefined LAN port (defined on some FortiGate models).
- On FortiGate models with dedicated MGMT interfaces, dedicated DMZ interfaces, dedicated WAN interfaces, and pre-defined LAN interfaces, the default management access on interfaces is shown below. Outside of the interfaces listed below, management access must be explicitly enabled on interfaces – management services are enabled on specific interfaces and not globally.
 - Dedicated Management Interface
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP
 - HTTPS
 - HTTP
 - Dedicated WAN1/WAN2 Ports
 - Ping
 - FMG-Access (fgfm)
 - Dedicated DMZ Port
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP
 - HTTPS
 - HTTP
 - Pre-Defined LAN Port
 - Ping
 - FMG-Access (fgfm)
 - CAPWAP
 - HTTPS
 - HTTP

Network security

This section describes FortiOS and FortiGate network security features.

Network interfaces

The following are disabled by default on each FortiGate interface:

- Broadcast forwarding
- STP forwarding

- VLAN forwarding
- L2 forwarding
- Netbios forwarding
- Ident accept

For more information, see [Disable unused protocols on interfaces on page 1581](#).

TCP sequence checking

FortiOS uses TCP sequence checking to ensure a packet is part of a TCP session. By default, anti-replay protection is strict, which means that if a packet is received with sequence numbers that fall out of the expected range, FortiOS drops the packet. Strict anti-replay checking performs packet sequence checking and ICMP anti-replay checking with the following criteria:

- The SYN, FIN, and RST bit cannot appear in the same packet.
- FortiOS does not allow more than 1 ICMP error packet to go through before it receives a normal TCP or UDP packet.
- If FortiOS receives an RST packet, FortiOS checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- For each new session, FortiOS checks to determine if the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value.

Reverse path forwarding

FortiOS implements a mechanism called Reverse Path Forwarding (RPF), or Anti Spoofing, to block an IP packet from being forwarded if its source IP does not:

- belong to a locally attached subnet (local interface), or
- be in the routing domain of the FortiGate from another source (static route, RIP, OSPF, BGP).

If those conditions are not met, FortiOS silently drops the packet.

FIPS and Common Criteria

FortiOS has received NDPP, EAL2+, and EAL4+ based FIPS and Common Criteria certifications. Common Criteria evaluations involve formal rigorous analysis and testing to examine security aspects of a product or system. Extensive testing activities involve a comprehensive and formally repeatable process, confirming that the security product functions as claimed by the manufacturer. Security weaknesses and potential vulnerabilities are specifically examined during an evaluation.

To see Fortinet's complete history of FIPS/CC certifications go to the following URL and add Fortinet to the Vendor field:

<https://csrc.nist.gov/projects/cryptographic-module-validation-program/validated-modules/search>

PSIRT advisories

The FortiGuard Labs Product Security Incident Response Team (PSIRT) continually tests and gathers information about Fortinet hardware and software products, looking for vulnerabilities and weaknesses. Any such findings are fed back to Fortinet's development teams and serious issues are described along with protective solutions. The PSIRT regulatory releases PSIRT advisories when issues are found and corrected. Advisories are listed at <https://www.fortiguards.com/psirt>.

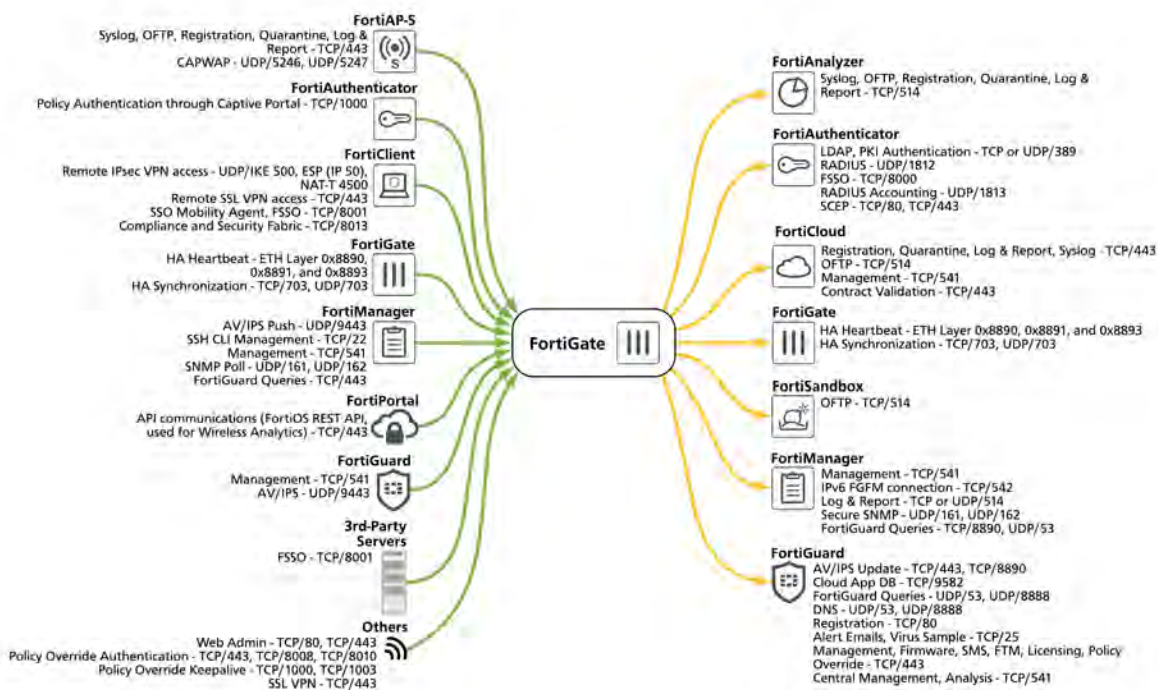

FortiOS ports and protocols

Communication to and from FortiOS is strictly controlled and only selected ports are opened for supported functionality such as administrator logins and communication with other Fortinet products or services.

Accessing FortiOS using an open port is protected by authentication, identification, and encryption requirements. As well, ports are only open if the feature using them is enabled.

FortiOS open ports

The following diagram and tables shows the incoming and outgoing ports that are potentially opened by FortiOS. For more details about open ports and the communication protocols that FortiOS uses, see the document [Fortinet Communication Ports and Protocols](#).

Incoming ports		
Purpose		Protocol/Port
FortiAP-S	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/443
	CAPWAP	UDP/5246, UDP/5247
FortiAuthenticator	RADIUS	UDP/1812
	FSSO	TCP/8000
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	Management	TCP/541
	AV/IPS	UDP/9443
FortiManager	AV/IPS Push	UDP/9443
	SSH CLI Management	TCP/22
	Management	TCP/541
	SNMP Poll	UDP/161, UDP/162
	FortiGuard Queries	TCP/443
FortiPortal	API communications (FortiOS REST API, used for Wireless Analytics)	TCP/443
Others	Web Admin	TCP/80, TCP/443
	FSSO	TCP/8000
	Policy Override Authentication	TCP/443, TCP/8008, TCP/8010
	FortiClient Portal	TCP/8009
	Policy Override Keepalive	TCP/1000, TCP/1003
	SSL VPN	TCP/10443
3rd-Party Servers	FSSO	TCP/8000

Outgoing ports		
Purpose		Protocol/Port
FortiAnalyzer	Syslog, OFTP, Registration, Quarantine, Log & Report	TCP/514
FortiAuthenticator	LDAP, PKI Authentication	TCP or UDP/389
FortiCloud	Registration, Quarantine, Log & Report, Syslog	TCP/443
	OFTP	TCP/514
	Management	TCP/541
	Contract Validation	TCP/443
FortiGate	HA Heartbeat	ETH Layer 0x8890, 0x8891, and 0x8893
	HA Synchronization	TCP/703, UDP/703
FortiGuard	AV/IPS Update	TCP/443, TCP/8890
	Cloud App DB	TCP/9582
	FortiGuard Queries	UDP/53, UDP/8888
	DNS	UDP/53, UDP/8888
	Registration	TCP/80
	Alert Email, Virus Sample	TCP/25
	Management, Firmware, SMS, FTM, Licensing, Policy Override	TCP/443
	Central Management, Analysis	TCP/541
FortiManager	Management	TCP/541
	IPv6 FGFM connection	TCP/542
	Log & Report	TCP or UDP/514
	Secure SNMP	UDP/161, UDP/162
	FortiGuard Queries	TCP/8890, UDP/53
FortiSandbox	OFTP	TCP/514

Note that, while a proxy is configured, FortiGate uses the following URLs to access the FortiGuard Distribution Network (FDN):

- **update.fortiguard.net**
- **service.fortiguard.net**
- **support.fortinet.com**

Closing open ports

You can close open ports by disabling the feature that opens them. For example, if FortiOS is not managing a FortiAP then the CAPWAP feature for managing FortiAPs can be disabled, closing the CAPWAP port.

The following sections of this document described a number of options for closing open ports:

- [Use local-in policies to close open ports or restrict access on page 1582](#)
- [Disable unused protocols on interfaces on page 1581](#)

Security best practices

This chapter describes some techniques and best practices that you can use to improve FortiOS security.

Install the FortiGate unit in a physically secure location

A good place to start with is physical security. Install your FortiGate in a secure location, such as a locked room or one with restricted access. A restricted location prevents unauthorized users from getting physical access to the device.

If unauthorized users have physical access, they can disrupt your entire network by disconnecting your FortiGate (either by accident or on purpose). They could also connect a console cable and attempt to log into the CLI. Also, when a FortiGate unit reboots, a person with physical access can interrupt the boot process and install different firmware.

Register your product with Fortinet Support

You need to register your Fortinet product with Fortinet Support to receive customer services, such as firmware updates and customer support. You must also register your product for FortiGuard services, such as up-to-date antivirus and IPS signatures. Register your product by visiting <https://support.fortinet.com>.

Keep your FortiOS firmware up to date

Always keep FortiOS up to date. The most recent version is the most stable and has the most bugs fixed and vulnerabilities removed.

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you register your FortiGate or FortiOS VM, download firmware updates from the support web site, <https://support.fortinet.com>.

Before you install any new firmware, be sure to follow these steps:

- Review the Release Notes for the latest firmware release.
- Review the [Supported Upgrade Paths](#) guide to determine the best path to take from your current version of FortiOS to the latest version.
- Back up the current configuration.

Only FortiGate administrators who have read and write privileges can upgrade the FortiOS firmware.

System administrator best practices

This section describes a collection of changes you can implement to make administrative access to the GUI and CLI more secure.

Disable administrative access to the external (Internet-facing) interface

When possible, don't allow administration access on the external (Internet-facing) interface.

To disable administrative access, go to **Network > Interfaces**, edit the external interface and disable HTTPS, PING, HTTP, SSH, and TELNET under **Administrative Access**.

From the CLI:

```
config system interface
  edit <external-interface-name>
    unset allowaccess
  end
```

Allow only HTTPS access to the GUI and SSH access to the CLI

For greater security never allow HTTP or Telnet administrative access to a FortiGate interface, only allow HTTPS and SSH access. You can change these settings for individual interfaces by going to **Network > Interfaces** and adjusting the administrative access to each interface.

From the CLI:

```
config system interface
  edit <interface-name>
    set allowaccess https ssh
  end
```

Require TLS 1.2 for HTTPS administrator access

Use the following command to require TLS 1.2 for HTTPS administrator access to the GUI:

```
config system global
  set admin-https-ssl-versions tlsv1-2
end
```

TLS 1.2 is currently the most secure SSL/TLS supported version for SSL-encrypted administrator access.

Re-direct HTTP GUI logins to HTTPS

Go to **System > Settings > Administrator Settings** and enable **Redirect to HTTPS** to make sure that all attempted HTTP login connections are redirected to HTTPS.

From the CLI:

```
config system global
    set admin-https-redirect enable
end
```

Change the HTTPS and SSH admin access ports to non-standard ports

Go to **System > Settings > Administrator Settings** and change the HTTPS and SSH ports.

You can change the default port configurations for HTTPS and SSH administrative access for added security. To connect to a non-standard port, the new port number must be included in the collection request. For example:

- If you change the HTTPS port to 7734, you would browse to `https://<ip-address>:7734`.
- If you change the SSH port to 2345, you would connect to `ssh admin@<ip-address>:2345`

To change the HTTPS and SSH login ports from the CLI:

```
config system global
    set admin-sport 7734
    set admin-ssh-port 2345
end
```

If you change to the HTTPS or SSH port numbers, make sure your changes do not conflict with ports used for other services.

Maintain short login timeouts

Set the idle timeout to a short time to avoid the possibility of an administrator walking away from their management computer and leaving it exposed to unauthorized personnel.

To set the administrator idle timeout, go to **System > Settings** and enter the amount of time for the **Idle timeout**. A best practice is to keep the default time of 5 minutes.

To set the administrator idle timeout from the CLI:

```
config system global
    set admintimeout 5
end
```

You can use the following command to adjust the grace time permitted between making an SSH connection and authenticating. The range can be between 10 and 3600 seconds, the default is 120 seconds (minutes). By shortening this time, you can decrease the chances of someone attempting a brute force attack from being successful. For example, you could set the time to 30 seconds.

```
config system global
    set admin-ssh-grace-time 30
end
```

Restrict logins from trusted hosts

Setting up trusted hosts for an administrator limits the addresses from where they can log into FortiOS. The trusted hosts configuration applies to all forms of administrative access including HTTPS, SSH, ping, and SNMP. When you identify a trusted host for an administrator account, FortiOS accepts that administrator's login only from one of the trusted hosts. A login, even with proper credentials, from a non-trusted host is dropped.

To identify trusted hosts, go to **System > Administrators**, edit the administrator account, enable **Restrict login to trusted hosts**, and add up to ten trusted host IP addresses.

To add two trusted hosts from the CLI:

```
config system admin
  edit <administrator-name>
    set trustedhost1 172.25.176.23 255.255.255.255
    set trustedhost2 172.25.177.0 255.255.255.0
  end
```

Trusted host IP addresses can identify individual hosts or subnets. Just like firewall policies, FortiOS searches through the list of trusted hosts in order and acts on the first match it finds. When you configure trusted hosts, start by adding specific addresses at the top of the list. Follow with more general IP addresses. You don't have to add addresses to all of the trusted hosts as long as all specific addresses are above all of the 0.0.0.0 0.0.0.0 addresses.

Set up two-factor authentication for administrators

FortiOS supports FortiToken and FortiToken Mobile 2-factor authentication. FortiToken Mobile is available for iOS and Android devices from their respective application stores.

Every registered FortiGate unit includes two trial tokens for free. You can purchase additional tokens from your reseller or from Fortinet.

To assign a token to an administrator, go to **System > Administrators** and select **Enable Two-factor Authentication** for each administrator.

Create multiple administrator accounts

Rather than allowing all administrators to access FortiOS with the same administrator account, you can create accounts for each person or each role that requires administrative access. This configuration allows you to track the activities of each administrator or administrative role.

If you want administrators to have different functions you can add different administrator profiles. Go to **System > Admin Profiles** and select **Create New**.

Modify administrator account lockout duration and threshold values

By default, the FortiGate sets the number of password retries at three, allowing the administrator a maximum of three attempts to log into their account before locking the account for a set amount of time.

Both the number of attempts (`admin-lockout-threshold`) and the wait time before the administrator can try to enter a password again (`admin-lockout-duration`) can be configured within the CLI.

To configure the lockout options:

```
config system global
  set admin-lockout-threshold <failed_attempts>
  set admin-lockout-duration <seconds>
end
```

The default value of `admin-lockout-threshold` is 3 and the range of values is between 1 and 10. The `admin-lockout-duration` is set to 60 seconds by default and the range of values is between 1 and 4294967295 seconds.

Keep in mind that the higher the lockout threshold, the higher the risk that someone may be able to break into the FortiGate unit.

Example:

To set the `admin-lockout-threshold` to one attempt and the `admin-lockout-duration` to a five minute duration before the administrator can try to log in again, enter the commands:

```
config system global
  set admin-lockout-threshold 1
  set admin-lockout-duration 300
end
```

If the time span between the first failed login attempt and the `admin-lockout-threshold` failed login attempt is less than `admin-lockout-duration`, the lockout will be triggered.

Rename the admin administrator account

You can improve security by renaming the admin account. To do this, create a new administrator account with the `super_admin` admin profile and log in as that administrator. Then go to **System > Administrators** and edit the admin administrator and change the **User Name**. Renaming the admin account makes it more difficult for an attacker to log into FortiOS.

Add administrator disclaimers

FortiOS can display a disclaimer before or after logging into the GUI or CLI (or both). In either case the administrator must read and accept the disclaimer before they can proceed.

Use the following command to display a disclaimer before logging in:

```
config system global
  set pre-login-banner enable
end
```

Use the following command to display a disclaimer after logging in:

```
config system global
  set post-login-banner enable
end
```

You can customize the replacement messages for these disclaimers by going to **System > Replacement Messages**. Select **Extended View** to view and edit the **Administrator** replacement messages.

From the CLI:

```
config system replacemsg admin pre_admin-disclaimer-text
config system replacemsg admin post_admin-disclaimer-text
```

Global commands for stronger and more secure encryption

This section describes some best practices for employing stronger and more secure encryption.

Turn on global strong encryption

Enter the following command to configure FortiOS to use only strong encryption and allow only strong ciphers (AES, 3DES) and digest (SHA1) for HTTPS, SSH, TLS, and SSL functions.

```
config sys global
    set strong-crypto enable
end
```

Disable MD5 and CBC for SSH

In some cases, you may not be able to enable strong encryption. For example, your FortiGate may be communicating with a system that does not support strong encryption. With `strong-crypto` disabled you can use the following options to prevent SSH sessions with the FortiGate from using less secure MD5 and CBC algorithms:

```
config sys global
    set ssh-hmac-md5 disable
    set ssh-cbc-cipher disable
end
```

Disable static keys for TLS

You can use the following command to prevent TLS sessions from using static keys (AES128-SHA, AES256-SHA, AES128-SHA256, AES256-SHA256):

```
config sys global
    set ssl-static-key-ciphers disable
end
```

Require larger values for Diffie-Hellman exchanges

Larger Diffie-Hellman values result in stronger encryption. Use the following command to force Diffie-Hellman exchanges to use 8192 bit values (the highest configurable DH value).

```
config sys global
    set dh-params 8192
end
```

Disable sending Malware statistics to FortiGuard

By default FortiOS periodically sends encrypted Malware statistics to FortiGuard. The Malware statistics record Antivirus, IPS, or Application Control events. This data is used to improved FortiGuard services. The Malware statistics that are sent do not include any personal or sensitive customer data. The information is not shared with any external parties and is used in accordance with Fortinet's [Privacy Policy](#).

To disable sending Malware statistics to FortiGuard, enter the following command:

```
config system global
    set fds-statistics disable
end
```

Disable auto USB installation

If USB installation is enabled, an attacker with physical access to a FortiGate could load a new configuration or firmware on the FortiGate using the USB port. You can disable USB installation by entering the following from the

CLI:

```
config system auto-install
    set auto-install-config disable
    set auto-install-image disable
end
```

Set system time by synchronizing with an NTP server

For accurate time, use an NTP server to set system time. Synchronized time facilitates auditing and consistency between expiry dates used in expiration of certificates and security protocols.

From the GUI go to **System > Settings > System Time** and select **Synchronize with NTP Server**. By default, this causes FortiOS to synchronize with Fortinet's FortiGuard secure NTP server.

From the CLI you can use one or more different NTP servers:

```
config system ntp
    set type custom
    set ntpsync enable
    config ntpserver
        edit 1
            set server <ntp-server-ip>
        next
        edit 2
            set server <other-ntp-server-ip>
    end
```

Enable password policies

Go to **System > Settings > Password Policy**, to create a password policy that all administrators must follow. Using the available options you can define the required length of the password, what it must contain (numbers, upper and lower case, and so on) and an expiry time.

Use the password policy feature to make sure all administrators use secure passwords that meet your organization's requirements.

Configure auditing and logging

For optimum security go to **Log & Report > Log Settings** enable **Event Logging**. For best results send log messages to FortiAnalyzer or FortiCloud.

From FortiAnalyzer or FortiCloud, you can view reports or system event log messages to look for system events that may indicate potential problems. You can also view system events by going to **FortiView > System Events**.

Establish an auditing schedule to routinely inspect logs for signs of intrusion and probing.

Encrypt logs sent to FortiAnalyzer/FortiManager

To keep information in log messages sent to FortiAnalyzer private, go to **Log & Report > Log Settings** and when you configure Remote Logging to FortiAnalyzer/FortiManager select **Encrypt log transmission**.

From the CLI.

```
config log {fortianalyzer | fortianalyzer2 | fortianalyzer3} setting
    set enc-algorithm high
```

```
end
```

Disable interfaces that not used

To disable an interface from the GUI, go to **Network > Interfaces**. Edit the interface to be disabled and set **Interface State** to **Disabled**.

From the CLI, to disable the port21 interface:

```
config system interface
  edit port21
    set status down
  end
```

Disable unused protocols on interfaces

You can use the `config system interface` command to disable unused protocols that attackers may attempt to use to gather information about a FortiGate unit. Many of these protocols are disabled by default. Using the `config system interface` command you can see the current configuration of each of these options for the selected interface and then choose to disable them if required.

```
config system interface
  edit <interface-name>
    set dhcp-relay-service disable
    set ptp-client disable
    set arpforward disable
    set broadcast-forward disable
    set l2forward disable
    set icmp-redirect disable
    set vlanforward disable
    set stpforward disable
    set ident-accept disable
    set ipmac disable
    set netbios-forward disable
    set security-mode none
    set device-identification disable
    set lldp-transmission disable
  end
```

Option	Description
dhcp-relay-service	Disable the DHCP relay service.
pttp-client	Disable operating the interface as a PPTP client.
arpforward	Disable ARP forwarding.
broadcast-forward	Disable forwarding broadcast packets.
l2forward	Disable layer 2 forwarding.
icmp-redirect	Disable ICMP redirect.

Option	Description
vlanforward	Disable VLAN forwarding.
stpforward	Disable STP forwarding.
ident-accept	Disable authentication for this interface. The interface will not respond to a connection with an authentication prompt.
ipmac	Disable IP/MAC binding.
netbios-forward	Disable NETBIOS forwarding.
security-mode	Set to <code>none</code> to disable captive portal authentication. The interface will not respond to a connection with a captive portal.
device-identification	Disable device identification.
lldp-transmission	Disable link layer discovery (LLDP).

Use local-in policies to close open ports or restrict access

You can also use local-in policies to close open ports or otherwise restrict access to FortiOS.

Close ICMP ports

Use the following command to close all ICMP ports on the WAN1 interface. The following example blocks traffic that matches the ALL_ICMP firewall service.

```
config firewall local-in-policy
edit 1
set intf wan1
set scraddr all
set dstaddr all
set action deny
set service ALL_ICMP
set schedule always
end
```

Close the BGP port

Use the following command to close the BGP port on the wan1 interface. The following example blocks traffic that matches the BGP firewall service.

```
config firewall local-in-policy
edit 1
set intf wan1
set scraddr all
set dstaddr all
set action deny
set service BGP
set schedule always
```

end

Chapter 14 - Hardware Acceleration

Hardware acceleration

This document describes the Security Processing Unit (SPU) hardware that Fortinet builds into FortiGate devices to accelerate traffic through FortiGate units. Three types of SPUs are described:

- Content processors (CPs) that accelerate a wide range of security functions
- Security processors (SPs) that accelerate specific security functions
- Network processors (NPs and NPLites) that offload network traffic to specialized hardware that is optimized to provide high levels of network throughput.

This FortiOS Handbook chapter contains the following sections:

[Hardware acceleration overview](#) describes the capabilities of FortiGate content processors (CPs), security processors (SPs) and network processors (NPs). This chapter also describes how to determine the hardware acceleration components installed in your FortiGate unit and contains some configuration details and examples.

[NP6 and NP6lite Acceleration](#) describes the FortiGate NP6 network processor.

[FortiGate NP6 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP6 processors.

[FortiGate NP6lite architectures on page 1682](#) contains details about the network processing architectures of FortiGate units that contain NP6Lite processors.

[NP4 and NP4Lite Acceleration](#) describes the FortiGate NP4 network processor.

[FortiGate NP4 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP4 processors.

Whats New in Hardware Acceleration for FortiOS 5.6

The following new hardware acceleration feature has been added to FortiOS 5.6.4.

- Per-session accounting is supported for FortiGates with NP6lite processors, [Enabling per-session accounting for offloaded NP6 or NP6lite sessions on page 1620](#).

Bandwidth control between the ISF and NP6 XAUI ports (437911)

In some cases, the Internal Switch Fabric (ISF) buffer size may be larger than the buffer size of an NP6 XAUI port that receives traffic from the ISF. If this happens, burst traffic from the ISF may exceed the capacity of an XAUI port and sessions may be dropped.

You can use the following command to configure bandwidth control between the ISF and XAUI ports. Enabling bandwidth control can smooth burst traffic and keep the XAUI ports from getting overwhelmed and dropping sessions.

Use the following command to enable bandwidth control:

```
config system npu
  set sw-np-bandwidth {0G | 2G | 4G | 5G | 6G}
```

end

The default setting is 0G which means no bandwidth control. The other options limit the bandwidth to 2Gbps, 4Gbps and so on.

SNMP/CLI monitoring capabilities of NP6 session table and session drift (441532)

In some cases sessions processed by NP6 processors may fail to be deleted leading to a large number of idle sessions. This is called session drift. New monitoring capabilities have been added to allow you to use SNMP to be alerted when the number of idle sessions becomes high. The SNMP fields allow you to see which NP6 processor has the abnormal number of idle sessions and you can use a diagnose command to delete them.

You can use the following diagnose command to determine if drift is occurring:

```
diagnose npu np6 sse-drift-summary
NPU    drv-drift
-----
np6_0  0
np6_1  0
-----
Sum    0
-----
```

The command output shows a drift summary for all the NP6 processors in the system, and shows the total drift. Normally the sum is 0. The previous command output, from a FortiGate-1500D, shows that the 1500D's two NP6 processors are not experiencing any drift.

If the sum is not zero, then extra idle sessions may be accumulating. You can use the following command to delete those sessions:

```
diagnose npu np6 sse-purge-drift <np6_id> [<time>]
```

Where <np6_id> is the number (starting with NP6_0 with a np6_id of 0) of the NP6 processor for which to delete idle sessions. <time> is the age in seconds of the idle sessions to be deleted. All idle sessions this age and older are deleted. The default time is 300 seconds.

The `diagnose npu np6 sse-stats <np6_id>` command output also includes a `drv-drift` field that shows the total drift for one NP6 processor.

For SNMP monitoring, the following MIB fields have been added. These fields allow you to use SNMP to monitor more session table information for NP6 processors including drift for each NP6 processor.

```
FORTINET-FORTIGATE-MIB::fgNPUNumber.0 = INTEGER: 2
FORTINET-FORTIGATE-MIB::fgNPUName.0 = STRING: NP6
FORTINET-FORTIGATE-MIB::fgNPUDrvDriftSum.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.1 = INTEGER: 1
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.0 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.1 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.0 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.1 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.1 = INTEGER: 0
```

NP6 Host Protection Engine (HPE) adds protection for DDoS attacks (363398)

NP6 processors now include HPE functionality that can protect networks from DoS attacks by categorizing incoming packets based on packet rate and processing cost and applying packet shaping to packets that can

cause DoS attacks. You can use the options in the following CLI command to limit the number packets per second received for various packet types by each NP6 processor. This rate limiting is applied very efficiently because it is done in hardware by the NP6 processor.

HPE protection is disable by default. You can use the following command to enable HPE protection for the NP6_0 NP6 processor:

```
config system np6
  edit np6_0
    config hpe
      set enable-shaper enable
    end
```

HPE can be enabled and configured separately for each NP6 processor. When enabled, the default configuration is designed to provide basic DoS protection. You can use the following command to adjust the HPE settings in real time if you network is experiencing an attack. For example, the following command allows you to configure HPE settings for np6_0.

```
config system np6
  edit np6_0
    config hpe
      set tcpsyn-max
      set tcp-max
      set udp-max
      set icmp-max
      set sctp-max
      set esp-max
      set ip-frag-max
      set ip-others-max
      set arp-max
      set l2-others-max
      set enable-shaper {disable | enable}
    end
```

Where:

tcpsyn-max applies shaping based on the maximum number of TCP SYN packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.

tcp-max applies shaping based on the maximum number of TCP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 5,000,000 pps.

udp-max applies shaping based on the maximum number of UDP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 5,000,000 pps.

icmp-max applies shaping based on the maximum number of ICMP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 1,000,000 pps.

sctp-max applies shaping based on the maximum number of SCTP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

esp-max NPU HPE shaping based on the maximum number of IPsec ESP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

ip-frag-max applies shaping based on the maximum number of fragmented IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

ip-others-max applies shaping based on the maximum number of other IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

`arp-max` applies shaping based on the maximum number of ARP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 1,000,000 pps.

`l2-others-max` applies shaping based on the maximum number of other layer 2 packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

Improved visibility of SPU and nTurbo hardware acceleration (389711)

All hardware acceleration hardware has been renamed Security Processing Units (SPUs). This includes NPx and CPx processors.

SPU and nTurbo data is now visible in a number of places on the GUI. For example, the Active Sessions column pop-up in the firewall policy list and the Sessions dashboard widget.

The following example shows the Sessions dashboard widget tracking SPU and nTurbo sessions. **Current sessions** shows the total number of sessions, **SPU** shows the percentage of these sessions that are SPU sessions and **Nturbo** shows the percentage that are nTurbo sessions.

You can also add SPU filters to many FortiView pages.

NP4Lite option to disable offloading ICMP traffic in IPsec tunnels (383939)

In some cases ICMP traffic in IPsec VPN tunnels may be dropped by the NP4Lite processor due to a bug with the NP4Lite firmware. You can use the following command to avoid this problem by preventing the NP4Lite processor from offloading ICMP sessions in IPsec VPN tunnels. This command is only available on FortiGate models with NP4Lite processors, such as the FortiGate/FortiWiFi-60D.

```
config system npu
    set process-icmp-by-host {disable | enable}
end
```

The option is disabled by default and all ICMP traffic in IPsec VPN tunnels is offloaded where possible. If you are noticing that ICMP packets in IPsec VPN tunnels are being dropped you can disable this option and have all ICMP traffic processed by the CPU and not offloaded to the NP4Lite.

NP6 IPv4 invalid checksum anomaly checking (387675)

The following new options have been added to NP6 processors to check for IPv4 checksum errors in IPv4, TCP, UDP, and ICMP packets.

```
config system np6
  edit {np6_0 | np6_1 | ...}
    config fp-anomaly
      set ipv4-csum-err {drop | trap-to-host}
      set tcp-csum-err {drop | trap-to-host}
      set udp-csum-err {drop | trap-to-host}
      set icmp-csum-err {drop | trap-to-host}
    end
```

You can use the new options to either drop packets with checksum errors (the default) or send them to the CPU for processing. Normally you would want to drop these packets.

As well, note that when configuring NP6 anomaly protection, the separate options `config fp-anomaly-v4` and `config fp-anomaly-v6` have been combined under `config fp-anomaly`.

Stripping clear text padding and IPsec session ESP padding (416950)

In some situations, when clear text or ESP packets in IPsec sessions may have large amounts of layer 2 padding, the NP6 IPsec engine may not be able to process them and the session may be blocked.

If you notice dropped IPsec sessions, you could try using the following CLI options to cause the NP6 processor to strip clear text padding and ESP padding before sending the packets to the IPsec engine. With padding stripped, the session can be processed normally by the IPsec engine.

Use the following command to strip ESP padding:

```
config system npu
  set strip-esp-padding enable
  set strip-clear-text-padding enable
end
```

Stripping clear text and ESP padding are both disabled by default.

Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces (392436)

Due to NP6 internal packet buffer limitations, some offloaded packets received at a 10Gbps interface and destined for a 1Gbps interface can be dropped, reducing performance for TCP and IP tunnel traffic. If you experience this performance reduction, you can use the following command to disable offloading sessions passing from 10Gbps interfaces to 1Gbps interfaces:

```
config system npu
  set host-shortcut-mode host-shortcut
end
```

Select `host-shortcut` to stop offloading TCP and IP tunnel packets passing from 10Gbps interfaces to 1Gbps interfaces. TCP and IP tunnel packets passing from 1Gbps interfaces to 10Gbps interfaces are still offloaded as normal.

If `host-shortcut` is set to the default `bi-directional` setting, packets in both directions are offloaded.

Hardware acceleration overview

Most FortiGate models have specialized acceleration hardware, (called Security Processing Units (SPUs)) that can offload resource intensive processing from main processing (CPU) resources. Most FortiGate units include specialized content processors (CPs) that accelerate a wide range of important security processes such as virus scanning, attack detection, encryption and decryption. (Only selected entry-level FortiGate models do not include a CP processor.) Many FortiGate models also contain security processors (SPs) that accelerate processing for specific security features such as IPS and network processors (NPs) that offload processing of high volume network traffic.

Content processors (CP4, CP5, CP6, CP8, and CP9)

Most FortiGate models contain FortiASIC Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 and CP9 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

CP9 capabilities

The CP9 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration with over 10Gbps throughput
 - IPS pre-scan
 - IPS signature correlation
 - Full match processors
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES128/192/256 in accordance with FIPS46-3/FIPS81/FIPS197
 - MD5/SHA-1/SHA256/384/512-96/128/192/256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
 - ESN mode
 - GCM support for NSA "Suite B" (RFC6379/RFC6460) including GCM-128/256; GMAC-128/256
- Key Exchange Processor that supports high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primary checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - True Random Number generator
 - Elliptic Curve support for NSA "Suite B"
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly (4k for DH and 8k for RSA with CRT)
- DLP fingerprint support
 - TTTD (Two-Thresholds-Two-Divisors) content chunking
 - Two thresholds and two divisors are configurable

CP8 capabilities

The CP8 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
 - ARC4 in compliance with RC4
 - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primarily checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - Random Number generator compliance with ANSI X9.31
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

CP6 capabilities

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor
- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

CP5 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPSEC Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

CP4 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC
- IPSEC protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
get hardware status
Model name: FortiGate-100D
ASIC version: CP8
ASIC SRAM: 64M
CPU: Intel(R) Atom(TM) CPU D525 @ 1.80GHz
Number of CPUs: 4
RAM: 1977 MB
Compact Flash: 15331 MB /dev/sda
Hard disk: 15272 MB /dev/sda
USB Flash: not available
Network Card chipset: Intel(R) PRO/1000 Network Connection (rev.0000)
Network Card chipset: bcm-sw Ethernet driver 1.0 (rev.)
```

The ASIC version line lists the content processor model number.

Viewing SSL acceleration status

You can view the status of SSL acceleration using the following command:

```
get vpn status ssl hw-acceleration-status
Acceleration hardware detected: kxp=on cipher=on
```

Where kxp means key exchange acceleration.

Disabling CP offloading for firewall policies

If you want to completely disable offloading to CP processors for test purposes or other reasons, you can do so in security policies. Here are some examples:

For IPv4 security policies.

```
config firewall policy
edit 1
set auto-asic-offload disable
end
```

For IPv6 security policies.

```
config firewall policy6
edit 1
set auto-asic-offload disable
end
```

For multicast security policies.

```
config firewall multicast-policy
edit 1
set auto-asic-offload disable
end
```

Disabling `auto-asic-offload` also disables NP offloading.

Security processors (SPs)

FortiGate Security Processing (SP) modules, such as the SP3 but also including the XLP, XG2, XE2, FE8, and CE4, work at both the interface and system level to increase overall system performance by accelerating specialized security processing. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments.

SP processors include their own IPS engine which is similar to the FortiOS IPS engine but with the following limitations:

- The SP IPS engine does not support SSL deep inspection. When you have SSL deep inspection enabled for a security policy that includes flow-based inspection or IPS, offloading to the SP is disabled and traffic is processed by the FortiGate CPU and CP processors.
- The SP IPS engine does not support FortiGuard Web Filtering. When you enable flow-based FortiGuard Web Filtering on a FortiGate unit with an SP processor, the SP processor cannot perform FortiGuard lookups and web pages fail to load.

The following security processors are available:

- The SP3 (XLP) is built into the FortiGate-5101B and provides IPS acceleration. No special configuration is required. All IPS processing, including traffic accepted by IPv4 and IPv6 traffic policies and IPv4 and IPv6 DoS policies is accelerated by the built-in SP3 processors.
- The FMC-XG2 is an FMC module with two 10Gb/s SPF+ interfaces that can be used on FortiGate-3950B and FortiGate-3951B units.
- The FortiGate-3140B also contains a built-in XG2 using ports 19 and 20.
- The ADM-XE2 is a dual-width AMC module with two 10Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.
- The ADM-FE8 is a dual-width AMC module with eight 1Gb/s interfaces that can be used with the FortiGate-3810A.
- The ASM-CE4 is a single-width AMC module with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an SP processor. If you disable SP offloading, traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for those policies. You can also use the following command to disable all IPS offloading:

```
config ips global
set np-accel-mode none
set cp-accel-mode none
end
```

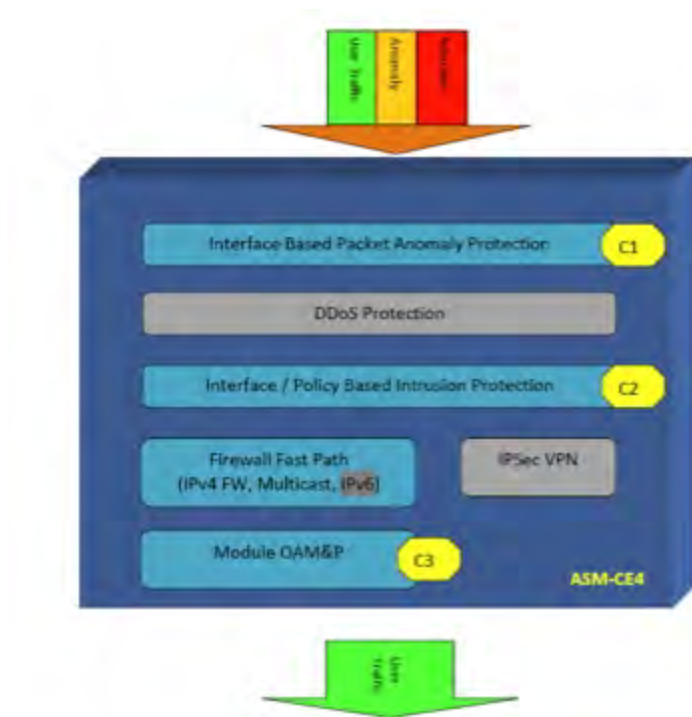

SP Processing Flow

SP processors provide an integrated high performance fast path multilayer solution for both intrusion protection and firewall functions. The multilayered protection starts from anomaly checking at packet level to ensure each packet is sound and reasonable. Immediately after that, a sophisticated set of interface based packet anomaly protection, DDoS protection, policy based intrusion protection, firewall fast path, and behavior based methods are employed to prevent DDoS attacks from the rest of system.

Then the packets enter an interface/policy based intrusion protection system,

where each packet is evaluated against a set of signatures. The end result is streams of user packets that are free of anomaly and attacks, entering the fast path system for unicast or multicast fast path forwarding.

SP processing flow

Displaying information about security processing modules

You can display information about installed SP modules using the CLI command

```
diagnose npu spm
```

For example, for the FortiGate-5101C:

```
FG-5101C # diagnose npu spm list
Available SP Modules:
```

ID	Model	Slot	Interface
0	xh0	built-in	port1, port2, port3, port4, base1, base2, fabric1, fabric2 eth10, eth11, eth12, eth13 eth14, eth15, eth16, eth17 eth18, eth19

You can also use this command to get more info about SP processing. This example shows how to display details about how the module is processing sessions using the syn proxy.

```
diagnose npu spm dos synproxy <sp_id>
```

This is a partial output of the command:

```
Number of proxied TCP connections : 0
Number of working proxied TCP connections : 0
Number of retired TCP connections : 0
Number of valid TCP connections : 0
Number of attacks, no ACK from client : 0
Number of no SYN-ACK from server : 0
Number of reset by server (service not supported): 0
Number of established session timeout : 0
Client timeout setting : 3 Seconds
Server timeout setting : 3 Seconds
```

Network processors (NP1, NP2, NP3, NP4, NP4Lite, NP6 and NP6Lite)

FortiASIC network processors work at the interface level to accelerate traffic by offloading traffic from the main CPU. Current models contain NP4, NP4Lite, NP6, and NP6lite network processors. Older FortiGate models include NP1 network processors (also known as FortiAccel, or FA2) and NP2 network processors.

The traffic that can be offloaded, maximum throughput, and number of network interfaces supported by each varies by processor model:

- NP6 supports offloading of most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a maximum throughput of 40 Gbps using 4 x 10 Gbps XAUI or Quad Serial Gigabit Media Independent Interface (QSGMII) interfaces or 3 x 10 Gbps and 16 x 1 Gbps XAUI or QSGMII interfaces. For details about the NP6 processor, see [NP6 and NP6lite Acceleration on page 1603](#) and for information about FortiGate models with NP6 processors, see [FortiGate NP6 architectures on page 1625](#).
- NP6lite is similar to the NP6 but with a lower throughput and some functional limitations (for example, the NP6lite does not offload CAPWAP traffic). The NP6lite has a maximum throughput of 10 Gbps using 2x QSGMII and 2x Reduced gigabit media-independent interface (RGMII) interfaces. For details about the NP6 processor, see [NP6Lite processors on page 1605](#) and for information about FortiGate models with NP6 processors, see [FortiGate NP6lite architectures on page 1682](#).
- NP4 supports offloading of most IPv4 firewall traffic and IPsec VPN encryption. The NP4 has a capacity of 20 Gbps through 2 x 10 Gbps interfaces. For details about NP4 processors, see [NP4 and NP4Lite Acceleration on page 1685](#) and for information about FortiGate models with NP4 processors, see [FortiGate NP4 architectures on page 1696](#).
- NP4lite is similar to the NP4 but with a lower throughput (but with about half the performance) and some functional limitations.
- NP2 supports IPv4 firewall and IPsec VPN acceleration. The NP2 has a capacity of 2 Gbps through 2 x 10 Gbps interfaces or 4 x 1 Gbps interfaces.
- NP1 supports IPv4 firewall and IPsec VPN acceleration with 2 Gbps capacity. The NP1 has a capacity of 2 Gbps through 2 x 1 Gbps interfaces.
 - The NP1 does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1 ports. Maximum frame size for NP2, NP4, and NP6 processors is 9216 bytes.
 - For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Sessions that require proxy-based security features (for example, virus scanning, IPS, application control and so on) are not fast pathed and must be processed by the CPU. Sessions that require flow-based security features can be offloaded to NP4 or NP6 network processors if the FortiGate supports NTurbo.

Determining the network processors installed on your FortiGate unit

Use either of the following command to list the NP6 processors in your FortiGate unit:

```
get hardware npu np6 port-list
diagnose npu np6 port-list
```

Use either of the following command to list the NP6lite processors in your FortiGate unit:

```
get hardware npu np6lite port-list
diagnose npu np6lite port-list
```

To list other network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
<model> can be legacy, np1, np2 or np4.
```

The output lists the interfaces that have the specified processor. For example, for a FortiGate-5001B:

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board          port1 port2 port3 port4
        fabric1 base1 npu0-vlink0 npu0-vlink1
1       On-board          port5 port6 port7 port8
        fabric2 base2 npu1-vlink0 npu1-vlink1
```

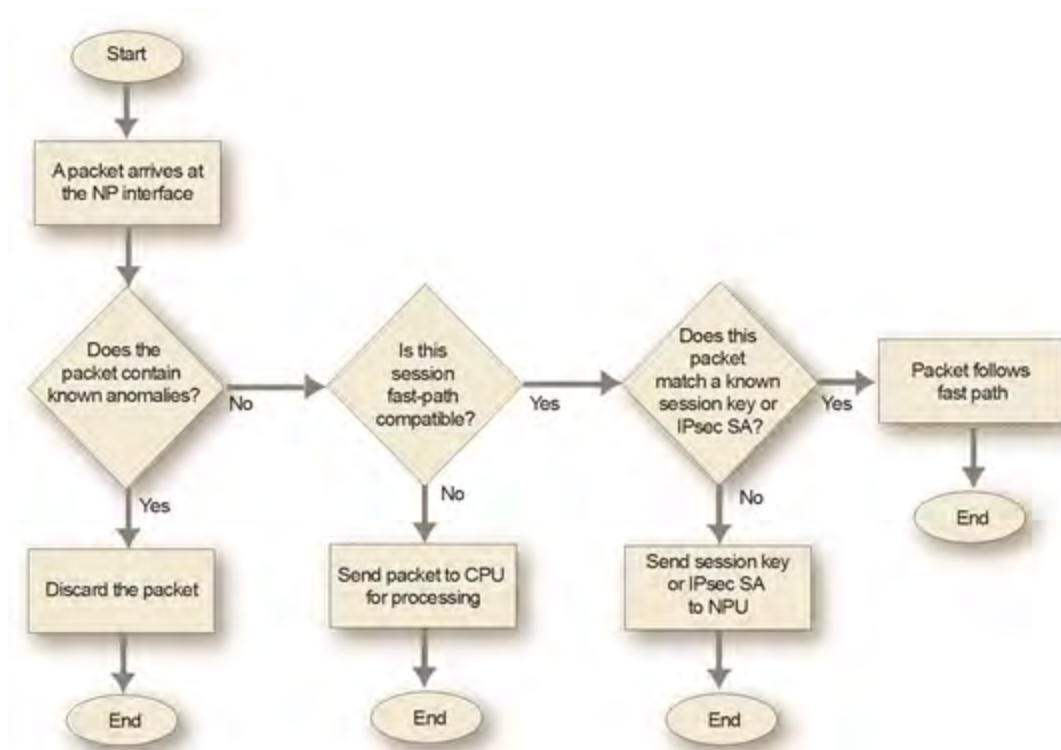

The npu0-vlink0, npu1-vlink1 etc interfaces are used for accelerating inter-VDOM links.

How NP hardware acceleration alters packet flow

NP hardware acceleration generally alters packet flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources (CPU).
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements. To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. The list of requirements depends on the processor, see [NP6 session fast path requirements on page 1603](#) or [NP4 session fast path requirements on page 1686](#). If the session can be fast pathed, the FortiGate unit sends the session key or IPsec security association (SA) and configured firewall processing action to the appropriate network processor.
3. Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received.
 - If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets that match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See [Offloading NP4 anomaly detection on page 1693](#).
 - The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. This is the actual offloading step. Performing this processing on the NP processor improves overall performance because the NP processor is optimized for this task. As well, overall FortiGate performance is improved because the CPU has fewer sessions to process.

NP network processor packet flow

- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the packet cannot be offloaded. The network processor sends the data to the FortiGate unit's CPU, which processes the packet.

Encryption and decryption of IPsec traffic originating from the FortiGate can utilize network processor encryption capabilities.

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

NP processors and traffic logging and monitoring

Except for the NP6, network processors do not count offloaded packets, and offloaded packets are not logged by traffic logging and are not included in traffic statistics and traffic log reports.

NP6 processors support per-session traffic and byte counters, Ethernet MIB matching, and reporting through messages resulting in traffic statistics and traffic log reporting.

Accelerated sessions on FortiView All Sessions page

When viewing sessions in the FortiView All Sessions console, NP4/ NP6 accelerated sessions are highlighted with an NP4 or NP6 icon. The tooltip for the icon includes the NP processor type and the total number of accelerated sessions.

You can also configure filtering to display FortiASIC sessions.

NP session offloading in HA active-active configuration

Network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

Configuring NP HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks offloaded to network processors by default. You can enter the following command to disable this feature:

```
configure system global
    set ipsec-hmac-offload disable
end
```

Software switch interfaces and NP processors

FortiOS supports creating a software switch by grouping two or more FortiGate physical interfaces into a single virtual or software switch interface. All of the interfaces in this virtual switch act like interfaces in a hardware switch in that they all have the same IP address and can be connected to the same network. You create a software switch interface from the CLI using the command `config system switch-interface`.

The software switch is a bridge group of several interfaces, and the FortiGate CPU maintains the mac-port table for this bridge. As a result of this CPU involvement, traffic processed by a software switch interface is not offloaded to network processors.

Disabling NP acceleration for individual IPsec VPN phase 1s

Use the following command to disable NP offloading for an interface-based IPsec VPN phase 1:

```
config vpn ipsec phase1-interface
    edit phase-1-name
        set npu-offload disable
    end
```

Use the following command to disable NP offloading for a policy-based IPsec VPN phase 1:

```
config vpn ipsec phase1
    edit phase-1-name
        set npu-offload disable
    end
```

The `npu-offload` option is enabled by default.

Disabling NP offloading for unsupported IPsec encryption or authentication algorithms

In general, more recent IPsec VPN encryption and authentication algorithms may not be supported by older NP processors. For example, NP4 network processors do not support SHA-256, SHA-384, and SHA-512. IPsec traffic with unsupported algorithms is not offloaded and instead is processed by the FortiGate CPU. In addition, this

configuration may cause packet loss and other performance issues. If you experience packet loss or performance problems you should set the `npu-offload` option to `disable`. Future FortiOS versions should prevent selecting algorithms not supported by the hardware.

Disabling NP offloading for firewall policies

Use the following options to disable NP offloading for specific security policies:

For IPv4 security policies.

```
config firewall policy
  edit 1
    set auto-asic-offload disable
  end
```

For IPv6 security policies.

```
config firewall policy6
  edit 1
    set auto-asic-offload disable
  end
```

For multicast security policies.

```
config firewall multicast-policy
  edit 1
    set auto-asic-offload disable
  end
```

Enabling strict protocol header checking disables all hardware acceleration

You can use the following command to cause the FortiGate to apply strict header checking to verify that a packet is part of a session that should be processed. Strict header checking includes verifying the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options, and verifying that ESP packets have the correct sequence number, SPI, and data length. If the packet fails header checking it is dropped by the FortiGate unit.

```
config system global
  check-protocol-header strict
end
```

Enabling strict header checking disables all hardware acceleration. This includes NP, SP, and CP processing.

sFlow and NetFlow and hardware acceleration

NP6 offloading is supported when you configure NetFlow for interfaces connected to NP6 processors.

Configuring sFlow on any interface disables all NP4 and NP6 offloading for all traffic on that interface. As well, configuring NetFlow on any interface disables NP4 offloading for all traffic on that interface.

Checking that traffic is offloaded by NP processors

A number of diagnose commands can be used to verify that traffic is being offloaded.

Using the packet sniffer

Use the packet sniffer to verify that traffic is offloaded. Offloaded traffic is not picked up by the packet sniffer so if you are sending traffic through the FortiGate unit and it is not showing up on the packet sniffer you can conclude

that it is offloaded.

```
diag sniffer packet port1 <option>
```

If you want the packet sniffer to be able to see offloaded traffic you can temporarily disable offloading the traffic, run the packet sniffer to view it and then re-enable offloading. As an example, you may want to sniff the traffic that is accepted by a specific firewall policy. You can edit the policy and set the `auto-asic-offload` option to `disable` to disable offloading this traffic. You can also disable offloading for IPsec VPN traffic, see [Disabling NP acceleration for individual IPsec VPN phase 1s on page 1597](#).

Checking the firewall session offload tag

Use the `diagnose sys session list` command to display sessions. If the output for a session includes the `npu info` field you should see information about session being offloaded. If the output doesn't contain an `npu info` field then the session has not been offloaded.

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=34 expire=3565 timeout=3600
              flags=00000000 sockflag=00000000 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 policy_dir=0 tunnel=/
state=may_dirty npu
statistic(bytes/packets/allow_err): org=295/3/1 reply=60/1/1 tuples=2

          vlan=32779/0
```

Verifying IPsec VPN traffic offloading

The following commands can be used to verify IPsec VPN traffic offloading to NP processors.

```
diagnose vpn ipsec status
NP1/NP2/NP4_0/sp_0_0:
  null: 0 0
  des: 0 0
    3des: 4075 4074
  aes: 0 0

```

Dedicated Management CPU

The web-based manager and CLI of FortiGate units with NP6 and NP4 processors may become unresponsive when the system is under heavy processing load because NP6 or NP4 interrupts overload the CPUs preventing CPU cycles from being used for management tasks. You can resolve this issue by using the following command to dedicate CPU core 0 to management tasks.

```

config system npu
  set dedicated-management-cpu {enable | disable}
end

```

All management tasks are then processed by CPU 0 and NP6 or NP4 interrupts are handled by the remaining CPU cores.

Offloading flow-based content inspection with NTurbo and IPSA

You can use the following command to configure NTurbo and IPA Advanced (IPSA) offloading and acceleration of firewall sessions that have flow-based security profiles. This includes firewall sessions with IPS, application control, CASI, flow-based antivirus and flow-based web filtering.

```
config ips global
  set np-accel-mode {none | basic}
  set cp-accel-mode {none | basic | advanced}
end
```

NTurbo offloads firewall sessions with flow-based security profiles to NPx processors

NTurbo offloads firewall sessions that include flow-based security profiles to NP4 or NP6 network processors. Without NTurbo, or with NTurbo disabled, all firewall sessions that include flow-based security profiles are processed by the FortiGate CPU.

NTurbo can only offload firewall sessions containing flow-based security profiles if the session could otherwise have been offloaded except for the presence of the flow-based security profiles. If something else prevents the session from being offloaded, NTurbo will not offload that session.

Firewall sessions that include proxy-based security profiles are never offloaded to network processors and are always processed by the FortiGate CPU.

NTurbo creates a special data path to redirect traffic from the ingress interface to IPS, and from IPS to the egress interface. NTurbo allows firewall operations to be offloaded along this path, and still allows IPS to behave as a stage in the processing pipeline, reducing the workload on the FortiGate CPU and improving overall throughput.

NTurbo sessions still offload pattern matching and other processes to CP processors, just like normal flow-based sessions.

If NTurbo is supported by your FortiGate unit, you can use the following command to configure it:

```
config ips global
  set np-accel-mode {basic | none}
end
```

`basic` enables NTurbo and is the default setting for FortiGate models that support NTurbo. `none` disables NTurbo. If the `np-accel-mode` option is not available, then your FortiGate does not support NTurbo.

There are some special cases where sessions may not be offloaded by NTurbo, even when NTurbo is explicitly enabled. In these cases the sessions are handled by the FortiGate CPU.

- NP acceleration is disabled. For example, `auto-asic-offload` is disabled in the firewall policy configuration.
- The firewall policy includes proxy-based security profiles.
- The sessions require FortiOS session-helpers. For example, FTP sessions can not be offloaded to NP processors because FTP sessions use the FTP session helper.

- Interface policies or DoS policies have been added to the ingress or egress interface.
- Tunneling is enabled. Any traffic to or from a tunneled interface (IPSec, IPinIP, SSL VPN, GRE, CAPWAP, etc.) cannot be offloaded by NTurbo.

IPSA offloads flow-based advanced pattern matching to CPx processors

IPSA offloads advanced or enhanced pattern matching operations required for flow-based content processing to CP8 and CP9 Content Processors. IPSA offloads enhanced pattern matching for NTurbo firewall sessions and firewall sessions that are not offloaded to NP processors. When IPSA is turned on, flow-based pattern databases are compiled and downloaded to the content processors from the IPS engine and IPS database. Flow-based pattern matching requests are redirected to the CP hardware reducing the load on the FortiGate CPU and accelerating pattern matching.

IF IPSA is supported on your FortiGate unit, you can use the following command to configure it:

```
config ips global
    set cp-accel-mode {advanced | basic | none}
end
```

`basic` offloads basic pattern matching. `advanced` offloads more types of pattern matching resulting in higher throughput than basic mode. `advanced` is only available on FortiGate models with two or more CP8s or one or more CP9s. If the `cp-accel-mode` option is not available, then your FortiGate does not support IPSA.

On FortiGates with one CP8, the default `cp-accel-mode` is `basic`. Setting the mode to `advanced` does not change the types of pattern matching that are offloaded.

On FortiGates with two or more CP8s or one or more CP9s the default `cp-accel-mode` is `advanced`. You can set the mode to `basic` to offload fewer types of pattern matching.

Preventing packet ordering problems with NP4, NP6 and NP6lite FortiGates under heavy load

In some cases when FortiGate units with NP4, NP6, or NP6lite processors are under heavy load the packets used in the TCP 3-way handshake of some sessions may be transmitted by the FortiGate in the wrong order resulting in the TCP sessions failing.

If you notice TCP sessions failing when a FortiGate with NP4, NP6, or NP6lite processors is very busy you can enable `delay-tcp-npu-session` in the firewall policy receiving the traffic. This option resolves the problem by delaying the session to make sure that there is time for all of the handshake packets to reach the destination before the session begins transmitting data.

```
config firewall policy
    set delay-tcp-npu-session enable
end
```

NP6 and NP6lite Acceleration

NP6 and NP6lite network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

NP6lite processors have the same architecture and function in the same way as NP6 processors. See [NP6Lite processors on page 1605](#). All of the descriptions of NP6 processors in this document can be applied to NP6lite processors except where noted.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6.

The key to making this possible is an Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. Many FortiGate units with NP6 processors also have an ISF. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF. There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF.

Some FortiGate units, such as the FortiGate-1000D include multiple NP6 processors that are not connected by an ISF. Because the ISF is not present fast path acceleration is supported only between interfaces connected to the same NP6 processor. Since the ISF introduces some latency, models with no ISF provide low-latency network acceleration between network interfaces connected to the same NP6 processor.

Each NP6 has a maximum throughput of 40 Gbps using 4 x 10 Gbps XAUI or Quad Serial Gigabit Media Independent Interface (QSGMII) interfaces or 3 x 10 Gbps and 16 x 1 Gbps XAUI or QSGMII interfaces.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.
- The NP6 processors in some FortiGate units employ NP direct technology that removes the ISF. The result is very low latency but no inter-processor connectivity requiring you to make sure that traffic to be offloaded enters and exits the FortiGate through interfaces connected to the same NP processor.

NP6 session fast path requirements

NP6 processors can offload the following traffic and services:

- IPv4 and IPv6 traffic and NAT64 and NAT46 traffic (as well as IPv4 and IPv6 versions of the following traffic types where appropriate).
- Link aggregation (LAG) (IEEE 802.3ad) traffic and traffic from static redundant interfaces (see [Increasing NP6 offloading capacity using link aggregation groups \(LAGs\) on page 1609](#)).
- TCP, UDP, ICMP and SCTP traffic.
- IPsec VPN traffic, and offloading of IPsec encryption/decryption (including SHA2-256 and SHA2-512)
- NP6 processor IPsec engines support null, DES, 3DES, AES128, AES192, and AES256 encryption algorithms
- NP6 processor IPsec engines support null, MD5, SHA1, SHA256, SHA 384, and SHA512 authentication algorithms
- IPsec traffic that passes through a FortiGate without being unencrypted.
- Anomaly-based intrusion prevention, checksum offload and packet defragmentation .
- IPIP tunneling (also called IP in IP tunneling), SIT tunneling, and IPv6 tunneling sessions.
- Multicast traffic (including Multicast over IPsec).
- CAPWAP and wireless bridge traffic tunnel encapsulation to enable line rate wireless forwarding from FortiAP devices (not supported by the NP6lite).
- Traffic shaping and priority queuing for both shared and per IP traffic shaping.
- Syn proxying (not supported by the NP6lite).
- DNS session helper (not supported by the NP6lite).
- Inter-VDOM link traffic.

Sessions that are offloaded must be fast path ready. For a session to be fast path ready it must meet the following criteria:

- Layer 2 type/length must be 0x0800 for IPv4 or 0x86dd for IPv6 (IEEE 802.1q VLAN specification is supported)
- Layer 3 protocol can be IPv4 or IPv6
- Layer 4 protocol can be UDP, TCP, ICMP, or SCTP
- In most cases, Layer 3 / Layer 4 header or content modification sessions that require a session helper can be offloaded.
- Local host traffic (originated by the FortiGate unit) can be offloaded
- If the FortiGate supports, NTurbo sessions can be offloaded if they are accepted by firewall policies that include IPS, Application Control, CASI, flow-based antivirus, or flow-based web filtering.

Offloading Application layer content modification is not supported. This means that sessions are not offloaded if they are accepted by firewall policies that include proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, Anti-Spam, VoIP, ICAP, Web Application Firewall, or Proxy options.

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [Configuring individual NP6 processors on page 1614](#).

If a session is not fast path ready, the FortiGate unit will not send the session key or IPsec SA key to the NP6 processor. Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key or IPsec SA key to the network processor. Session key or IPsec SA key lookups then succeed for subsequent packets from the known session or IPsec SA.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for a network processor's network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP6.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

NP6Lite processors

The NP6Lite works the same way as the NP6. Being a lighter version, the NP6Lite has a lower capacity than the NP6. The NP6lite max throughput is 10 Gbps using 2x QSGMII and 2x Reduced gigabit media-independent interface (RGMII) interfaces.

Also, the NP6lite does not offload the following types of sessions:

- CAPWAP
- Syn proxy
- DNS session helper

NP6 and NP6Lite processors and sFlow and NetFlow

NP6 and NP6Lite offloading is supported when you configure NetFlow for interfaces connected to NP6 or NP6Lite processors. Offloading of other sessions is not affected by configuring NetFlow.

Configuring sFlow on any interface disables all NP6 and NP6Lite offloading for all traffic on that interface.

NP6 processors and traffic shaping

NP6-offloaded sessions support most types of traffic shaping. However, in bandwidth and out bandwidth traffic shaping, set using the following command, is not supported:

```
config system interface
  edit port1
    set outbandwidth <value>
    set inbandwidth <value>
  end
```

Configuring in bandwidth traffic shaping has no effect. Configuring out bandwidth traffic shaping imposes more limiting than configured, potentially reducing throughput more than expected.

NP Direct

On FortiGate devices with more than one NP6 processor, removing the Internal Switch Fabric (ISF) for NP Direct architecture provides direct access to the NP6 processors for the lowest latency forwarding. Because the NP6 processors are not connected, care must be taken with network design to make sure that all traffic to be offloaded enters and exits the FortiGate through interfaces connected to the same NP6 processor. As well Link Aggregation (LAG) interfaces should only include interfaces all connected to the same NP6 processor.

Example NP direct hardware with more than one NP6 processor includes:

- Ports 25 to 32 of the FortiGate-3700D in low latency mode.
- FortiGate-2000E
- FortiGate-2500E

Viewing your FortiGate NP6 processor configuration

Use either of the following commands to view the NP6 processor hardware configuration of your FortiGate unit:

```
get hardware npu np6 port-list
diagnose npu np6 port-list
```

If your FortiGate has NP6lite processors, you can use either of the following commands:

```
get hardware npu np6lite port-list
diagnose npu np6lite port-list
```

For example, for the FortiGate-5001D the output would be:

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading
np6_0	0	port3	10G	Yes
	1			
	2	base1	1G	Yes
	3			
	0-3	port1	40G	Yes
	0-3	fabric1	40G	Yes
	0-3	fabric3	40G	Yes
	0-3	fabric5	40G	Yes
np6_1	0			
	1	port4	10G	Yes
	2			
	3	base2	1G	Yes
	0-3	port2	40G	Yes
	0-3	fabric2	40G	Yes
	0-3	fabric4	40G	Yes

For more example output for different FortiGate models, see [FortiGate NP6 architectures on page 1625](#) and [FortiGate NP6lite architectures on page 1682](#).

You can also use the following command to view the offloading features enabled or disabled on each of the NP6 processors in your FortiGate unit:

```

diagnose npu npu-feature
-----
np_0      np_1
-----
Fastpath      Enabled    Enabled
Low-latency-mode Disabled  Disabled
Low-latency-cap No         No
IPv4 firewall Yes       Yes
IPv6 firewall Yes       Yes
IPv4 IPSec    Yes       Yes
IPv6 IPSec    Yes       Yes
IPv4 tunnel   Yes       Yes
IPv6 tunnel   Yes       Yes
GRE tunnel    No        No
IPv4 Multicast Yes       Yes
IPv6 Multicast Yes       Yes
CAPWAP        Yes       Yes

```

Optimizing NP6 performance by distributing traffic to XAUI links

On most FortiGate units with NP6 processors, the FortiGate interfaces are switch ports that connect to the NP6 processors with XAUI links. Packets pass from the interfaces to the NP6 processor over the XAUI links. Each NP6 processor has a 40 Gigabit bandwidth capacity. The four XAUI links each have a 10 Gigabit capacity for a total of 40 Gigabits.

On many FortiGate units with NP6 processors, the NP6 processors and the XAUI links are over-subscribed. Since the NP6 processors are connected by an Integrated Switch Fabric, you do not have control over how traffic is distributed to them. In fact traffic is distributed evenly by the ISF.

However, you can control how traffic is distributed to the XAUI links and you can optimize performance by distributing traffic evenly among the XAUI links. For example, if you have a very high amount of traffic passing between two networks, you can connect each network to interfaces connected to different XAUI links to distribute the traffic for each network to a different XAUI link.

For example, on a FortiGate-3200D (See [FortiGate-3200D fast path architecture on page 1649](#)), there are 48 10-Gigabit interfaces that send and receive traffic for two NP6 processors over a total of eight 10-Gigabit XAUI links. Each XAUI link gets traffic from six 10-Gigabit FortiGate interfaces. The amount of traffic that the FortiGate-3200D can offload is limited by the number of NP6 processors and the number of XAUI links. You can optimize the amount of traffic that the FortiGate-3200D can process by distributing it evenly amount the XAUI links and the NP6 processors.

You can see the Ethernet interface, XAUI link, and NP6 configuration by entering the `get hardware npu np6 port-list` command. For the FortiGate-3200D the output is:

```

get hardware npu np6 port-list
Chip   XAUI  Ports  Max   Cross-chip
       Ports  Speed  offloading
-----
np6_0  0      port1   10G   Yes
       0      port5   10G   Yes
       0      port10  10G   Yes
       0      port13  10G   Yes
       0      port17  10G   Yes
       0      port22  10G   Yes

```

	1	port2	10G	Yes
	1	port6	10G	Yes
	1	port9	10G	Yes
	1	port14	10G	Yes
	1	port18	10G	Yes
	1	port21	10G	Yes
	2	port3	10G	Yes
	2	port7	10G	Yes
	2	port12	10G	Yes
	2	port15	10G	Yes
	2	port19	10G	Yes
	2	port24	10G	Yes
	3	port4	10G	Yes
	3	port8	10G	Yes
	3	port11	10G	Yes
	3	port16	10G	Yes
	3	port20	10G	Yes
	3	port23	10G	Yes

np6_1	0	port26	10G	Yes
	0	port29	10G	Yes
	0	port33	10G	Yes
	0	port37	10G	Yes
	0	port41	10G	Yes
	0	port45	10G	Yes
	1	port25	10G	Yes
	1	port30	10G	Yes
	1	port34	10G	Yes
	1	port38	10G	Yes
	1	port42	10G	Yes
	1	port46	10G	Yes
	2	port28	10G	Yes
	2	port31	10G	Yes
	2	port35	10G	Yes
	2	port39	10G	Yes
	2	port43	10G	Yes
	2	port47	10G	Yes
	3	port27	10G	Yes
	3	port32	10G	Yes
	3	port36	10G	Yes
	3	port40	10G	Yes
	3	port44	10G	Yes
	3	port48	10G	Yes

In this command output you can see that each NP6 has for four XAUI links (0 to 3) and that each XAUI link is connected to six 10-gigabit Ethernet interfaces. To optimize throughput you should keep the amount of traffic being processed by each XAUI port to under 10 Gbps. So for example, if you want to offload traffic from four 10-gigabit networks you can connect these networks to Ethernet interfaces 1, 2, 3 and 4. This distributes the traffic from each 10-Gigabit network to a different XAUI link. Also, if you wanted to offload traffic from four more 10-Gigabit networks you could connect them to Ethernet ports 26, 25, 28, and 27. As a result each 10-Gigabit network would be connected to a different XAUI link.

Increasing NP6 offloading capacity using link aggregation groups (LAGs)

NP6 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A 802.3ad Link Aggregation and its management protocol, Link Aggregation Control Protocol (LACP) LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 30 Gbps link by adding three 10-Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP6 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP6 processor, traffic received by that LAG is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

If a FortiGate has two or more NP6 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP6 processors. You do this by adding physical interfaces connected to different NP6 processors to the same LAG.

Adding a second NP6 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP6 or tripled by adding a third. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP6s is supported by the integrated switch fabric (ISF) that allows multiple NP6 processors to share session information. Most FortiGate units with multiple NP6 processors also have an ISF. However, FortiGate modules such as the 1000D, 2000E, and 2500E do not have an ISF. If you attempt to add interfaces connected to different NP6 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP6 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPsec is configured on a LAG that has interfaces connected to multiple NP6 processors.
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP6 LAG group to 10Gbps.

NP6 processors and redundant interfaces

NP6 processors can offload sessions received by interfaces that are part of a redundant interface. You can combine two or more physical interfaces into a redundant interface to provide link redundancy. Redundant interfaces ensure connectivity if one physical interface, or the equipment on that interface, fails. In a redundant interface, traffic travels only over one interface at a time. This differs from an aggregated interface where traffic travels over all interfaces for distribution of increased bandwidth.

All offloaded traffic types are supported by redundant interfaces, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a redundant interface is offloaded by the NP6 processor connected to the interfaces in the redundant interface that receive the traffic to be offloaded. If all interfaces in a redundant interface are connected to the same NP6 processor, traffic received by that redundant interface is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

If a FortiGate has two or more NP6 processors connected by an integrated switch fabric (ISF), you can create redundant interfaces that include physical interfaces connected to different NP6 processors. However, with a redundant interface, only one of the physical interfaces is processing traffic at any given time. So you cannot use redundant interfaces to increase performance in the same way as you can with aggregate interfaces.

The ability to add redundant interfaces connected to multiple NP6s is supported by the integrated switch fabric (ISF) that allows multiple NP6 processors to share session information. Most FortiGate units with multiple NP6 processors also have an ISF. However, FortiGate models such as the 1000D, 2000E, and 2500E do not have an ISF. If you attempt to add interfaces connected to different NP6 processors to a redundant interface the system displays an error message.

Configuring Inter-VDOM link acceleration with NP6 processors

FortiGate units with NP6 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP6 processors there are two accelerated inter-VDOM links, each with two interfaces:
 - **npu0_vlink:**
 - npu0_vlink0
 - npu0_vlink1
 - **npu1_vlink:**
 - npu1_vlink0
 - npu1_vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP6 interfaces, enter the following CLI command to display the NP6-accelerated inter-VDOM links:

```
get system interface
...
== [ npu0_vlink0 ]
name: npu0_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu0_vlink1 ]
name: npu0_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu1_vlink0 ]
name: npu1_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable

== [ npu1_vlink1 ]
name: npu1_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
fragment: disable
...
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in the pair to the VDOMs that you want to offload traffic

between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**. This results in an accelerated inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
  end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0_vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0_vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0_vlink0
```

```

    set vlanid 100
next
edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0_vlink1
    set vlanid 100

```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP6 processor.

diagnose ip address list

```

IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1

Disabling offloading IPsec Diffie-Hellman key exchange

You can use the following command to disable using ASIC offloading to accelerate IPsec Diffie-Hellman key exchange for IPsec ESP traffic. By default hardware offloading is used. For debugging purposes or other reasons you may want this function to be processed by software.

Use the following command to disable using ASIC offloading for IPsec Diffie Hellman key exchange:

```
config system global
    set ipsec-asic-offload disable
end
```

Access control lists (ACLs)

Access Control Lists (ACLs) use NP6 offloading to drop IPv4 or IPv6 packets at the physical network interface before the packets are analyzed by the CPU. On a busy appliance this can really help the performance. This feature is available on FortiGates with NP6 processors and is not supported by FortiGates with NP6lite processors.

The ACL feature is available only on FortiGates with NP6-accelerated interfaces. ACL checking is one of the first things that happens to the packet and checking is done by the NP6 processor. The result is very efficient protection that does not use CPU or memory resources.

Use the following command to configure IPv4 ACL lists:

```
config firewall acl
    edit 0
        set status enable
        set interface <interface-name>
        set scraddr <firewall-address>
        set dstaddr <firewall-address>
        set service <firewall-service>
    end
```

Use the following command to configure IPv6 ACL lists:

```
config firewall acl6
    edit 0
        set status enable
        set interface <interface-name>
        set scraddr <firewall-address6>
        set dstaddr <firewall-address6>
        set service <firewall-service>
    end
```

Where:

<interface-name> is the interface on which to apply the ACL. There is a hardware limitation that needs to be taken into account. The ACL is a Layer 2 function and is offloaded to the ISF hardware, therefore no CPU resources are used in the processing of the ACL. It is handled by the inside switch chip which can do hardware acceleration, increasing the performance of the FortiGate. The ACL function is only supported on switch fabric driven interfaces.

<firewall-address> <firewall-address6> can be any of the address types used by the FortiGate, including address ranges. The traffic is blocked not on an either or basis of these addresses but the combination of the two, so that they both have to be correct for the traffic to be denied. To block all of the traffic from a specific address all you have to do is make the destination address ALL.

Because the blocking takes place at the interface based on the information in the packet header and before any processing such as NAT can take place, a slightly different approach may be required. For instance, if you are trying to protect a VIP which has an external address of x.x.x.x and is forwarded to an internal address of y.y.y.y, the destination address that should be used is x.x.x.x, because that is the address that will be in the packet's header when it hits the incoming interface.

<firewall-service> the firewall service to block. Use ALL to block all services.

Configuring individual NP6 processors

You can use the `config system np6` command to configure a wide range of settings for each of the NP6 processors in your FortiGate unit including enabling/disabling fastpath and low latency, enabling session accounting and adjusting session timeouts. As well you can set anomaly checking for IPv4 and IPv6 traffic.

You can also enable and adjust Host Protection Engine (HPE) to protect networks from DoS attacks by categorizing incoming packets based on packet rate and processing cost and applying packet shaping to packets that can cause DoS attacks.

The settings that you configure for an NP6 processor with the `config system np6` command apply to traffic processed by all interfaces connected to that NP6 processor. This includes the physical interfaces connected to the NP6 processor as well as all subinterfaces, VLAN interfaces, IPsec interfaces, LAGs and so on associated with the physical interfaces connected to the NP6 processor.

Some of the options for this command apply anomaly checking for NP6 sessions in the same way as the command described in [Offloading NP4 anomaly detection on page 1693](#) applies anomaly checking for NP4 sessions.

```
config system np6
  edit <np6-processor-name>
    set fastpath {disable | enable}
    set low-latency-mode {disable | enable}
    set per-session-accounting {all-enable | disable | enable-by-log}
    set session-timeout-random-range <range>
    set garbage-session-collector {disable | enable}
    set session-collector-interval <range>
    set session-timeout-interval <range>
    set session-timeout-random-range <range>
    set session-timeout-fixed {disable | enable}
    config hpe
      set tcpsyn-max <packets-per-second>
      set tcp-max <packets-per-second>
      set udp-max <packets-per-second>
      set icmp-max <packets-per-second>
      set sctp-max <packets-per-second>
      set esp-max <packets-per-second>
      set ip-frag-max <packets-per-second>
      set ip-others-max <packets-per-second>
      set arp-max <packets-per-second>
      set l2-others-max <packets-per-second>
```

```

    set enable-shaper {disable | enable}
config fp-anomaly
    set tcp-syn-fin {allow | drop | trap-to-host}
    set tcp_fin_noack {allow | drop | trap-to-host}
    set tcp_fin_only {allow | drop | trap-to-host}
    set tcp_no_flag {allow | drop | trap-to-host}
    set tcp_syn_data {allow | drop | trap-to-host}
    set tcp-winnuke {allow | drop | trap-to-host}
    set tcp-land {allow | drop | trap-to-host}
    set udp-land {allow | drop | trap-to-host}
    set icmp-land {allow | drop | trap-to-host}
    set icmp-frag {allow | drop | trap-to-host}
    set ipv4-land {allow | drop | trap-to-host}
    set ipv4-proto-err {allow | drop | trap-to-host}
    set ipv4-unknopt {allow | drop | trap-to-host}

    set ipv6-optjumbo {allow | drop | trap-to-host}
    set ipv6-opttunnel {allow | drop | trap-to-host}
    set ipv6-opthomeaddr {allow | drop | trap-to-host}
    set ipv6-optnsap {allow | drop | trap-to-host}
    set ipv6-optendpid {allow | drop | trap-to-host}
    set ipv6-optinvld {allow | drop | trap-to-host}
end

```

Command syntax

Command	Description	Default
fastpath {disable enable}	Enable fastpath acceleration to offload sessions to the NP6 processor. You can disable fastpath if you don't want the NP6 processor to offload sessions.	enable
low-latency-mode {disable enable}	Enable low-latency mode. In low latency mode the integrated switch fabric is bypassed. Low latency mode requires that packet enter and exit using the same NP6 processor. This option is only available for NP6 processors that can operate in low-latency mode, currently only np6_0 and np6_1 on the FortiGate-3700D and DX.	disable

Command	Description	Default
<code>per-session-accounting</code> { <code>all-enable</code> <code>disable</code> <code>enable-by-log</code> }	Disable NP6 per-session accounting or enable it and control how it works. If set to <code>enable-by-log</code> (the default) NP6 per-session accounting is only enabled if firewall policies accepting offloaded traffic have traffic logging enabled. If set to <code>all-enable</code> , NP6 per-session accounting is always enabled for all traffic offloaded by the NP6 processor. Enabling per-session accounting can affect performance.	<code>enable-by-log</code>
<code>garbage-session-collector</code> { <code>disable</code> <code>enable</code> }	Enable deleting expired or garbage sessions.	<code>disable</code>
<code>session-collector-interval</code> <range>	Set the expired or garbage session collector time interval in seconds. The range is 1 to 100 seconds.	64
<code>session-timeout-interval</code> <range>	Set the timeout for checking for and removing inactive NP6 sessions. The range is 0 to 1000 seconds.	40
<code>session-timeout-random-range</code> <range>	Set the random timeout for checking and removing inactive NP6 sessions. The range is 0 to 1000 seconds.	8
<code>session-timeout-fixed</code> { <code>disable</code> <code>enable</code> }	Enable to force checking for and removing inactive NP6 sessions at the <code>session-timeout-interval</code> time interval. Set to <code>disable</code> (the default) to check for and remove inactive NP6 sessions at random time intervals.	<code>disable</code>
config hpe		
<code>hpe</code>	Use the following options to use HPE to apply DDoS protection at the NP6 processor by limiting the number packets per second received for various packet types by each NP6 processor. This rate limiting is applied very efficiently because it is done in hardware by the NP6 processor.	
<code>enable-shaper</code> { <code>disable</code> <code>enable</code> }	Enable or disable HPE DDoS protection.	<code>disable</code>
<code>tcpsyn-max</code>	Limit the maximum number of TCP SYN packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000

Command	Description	Default
<code>tcp-max</code>	Limit the maximum number of TCP packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000
<code>udp-max</code>	Limit the maximum number of UDP packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.	5000000
<code>icmp-max</code>	Limit the maximum number of ICMP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>sctp-max</code>	Limit the maximum number of SCTP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>esp-max</code>	Limit the maximum number of ESP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>ip-frag-max</code>	Limit the maximum number of fragmented IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>ip-others-max</code>	Limit the maximum number of other types of IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>arp-max</code>	Limit the maximum number of ARP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
<code>l2-others-max</code>	Limit the maximum number of other layer-2 packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.	100000
config fp-anomaly		
<code>fp-anomaly</code>	Configure how the NP6 processor does traffic anomaly protection. In most cases you can configure the NP6 processor to allow or drop the packets associated with an attack or forward the packets that are associated with the attack to FortiOS (called <code>trap-to-host</code>). Selecting <code>trap-to-host</code> turns off NP6 anomaly protection for that anomaly. If you require anomaly protection but don't want to use the NP6 processor, you can select <code>trap-to-host</code> and enable anomaly protection with a DoS policy.	

Command	Description	Default
<code>tcp-syn-fin {allow drop trap-to-host}</code>	Detects TCP SYN flood SYN/FIN flag set anomalies.	allow
<code>tcp_fin_noack {allow drop trap-to-host}</code>	Detects TCP SYN flood with FIN flag set without ACK setting anomalies.	trap-to-host
<code>tcp_fin_only {allow drop trap-to-host}</code>	Detects TCP SYN flood with only FIN flag set anomalies.	trap-to-host
<code>tcp_no_flag {allow drop trap-to-host}</code>	Detects TCP SYN flood with no flag set anomalies.	allow
<code>tcp_syn_data {allow drop trap-to-host}</code>	Detects TCP SYN flood packets with data anomalies.	allow
<code>tcp-winnuke {allow drop trap-to-host}</code>	Detects TCP WinNuke anomalies.	trap-to-host
<code>tcp-land {allow drop trap-to-host}</code>	Detects TCP land anomalies.	trap-to-host
<code>udp-land {allow drop trap-to-host}</code>	Detects UDP land anomalies.	trap-to-host
<code>icmp-land {allow drop trap-to-host}</code>	Detects ICMP land anomalies.	trap-to-host
<code>icmp-frag {allow drop trap-to-host}</code>	Detects Layer 3 fragmented packets that could be part of a layer 4 ICMP anomalies.	allow
<code>ipv4-land {allow drop trap-to-host}</code>	Detects IPv4 land anomalies.	trap-to-host
<code>ipv4-proto-err {allow drop trap-to-host}</code>	Detects invalid layer 4 protocol anomalies.	trap-to-host
<code>ipv4-unknopt {allow drop trap-to-host}</code>	Detects unknown option anomalies.	trap-to-host
<code>ipv4-optrr {allow drop trap-to-host}</code>	Detects IPv4 with record route option anomalies.	trap-to-host
<code>ipv4-optssrr {allow drop trap-to-host}</code>	Detects IPv4 with strict source record route option anomalies.	trap-to-host
<code>ipv4-optlsrr {allow drop trap-to-host}</code>	Detects IPv4 with loose source record route option anomalies.	trap-to-host

Command	Description	Default
ipv4-optstream {allow drop trap-to-host}	Detects stream option anomalies.	trap-to-host
ipv4-optsecurity {allow drop trap-to-host}	Detects security option anomalies.	trap-to-host
ipv4-opttimestamp {allow drop trap-to-host}	Detects timestamp option anomalies.	trap-to-host
ipv4-csum-err {drop trap-to-host}	Detects IPv4 checksum errors.	drop
tcp-csum-err {drop trap-to-host}	Detects TCP checksum errors.	drop
udp-csum-err {drop trap-to-host}	Detects UDP checksum errors.	drop
icmp-csum-err {drop trap-to-host}	Detects ICMP checksum errors.	drop
ipv6-land {allow drop trap-to-host}	Detects IPv6 land anomalies	trap-to-host
ipv6-unknopt {allow drop trap-to-host}	Detects unknown option anomalies.	trap-to-host
ipv6-saddr-err {allow drop trap-to-host}	Detects source address as multicast anomalies.	trap-to-host
ipv6-daddr_err {allow drop trap-to-host}	Detects destination address as unspecified or loopback address anomalies.	trap-to-host
ipv6-optralert {allow drop trap-to-host}	Detects router alert option anomalies.	trap-to-host
ipv6-optjumbo {allow drop trap-to-host}	Detects jumbo options anomalies.	trap-to-host
ipv6-opttunnel {allow drop trap-to-host}	Detects tunnel encapsulation limit option anomalies.	trap-to-host
ipv6-opthomeaddr {allow drop trap-to-host}	Detects home address option anomalies.	trap-to-host
ipv6-optnsap {allow drop trap-to-host}	Detects network service access point address option anomalies.	trap-to-host

Command	Description	Default
<code>ipv6-optendpid {allow drop trap-to-host}</code>	Detects end point identification anomalies.	trap-to-host
<code>ipv6-optinvld {allow drop trap-to-host}</code>	Detects invalid option anomalies.	trap-to-host

Enabling per-session accounting for offloaded NP6 or NP6lite sessions

Per-session accounting is a logging feature that allows the FortiGate to report the correct bytes/pkt numbers per session for sessions offloaded to an NP6 or NP6lite processor. This information appears in traffic log messages as well as in FortiView. The following example shows the Sessions dashboard widget tracking SPU and nTurbo sessions. **Current sessions** shows the total number of sessions, **SPU** shows the percentage of these sessions that are SPU sessions and **Nturbo** shows the percentage that are nTurbo sessions.

You can hover over the SPU icon to see some information about the offloaded sessions.

You configure per-session accounting for each NP6 processor. For example, use the following command to enable per-session accounting for NP6_0 and NP6_1:

```
config system np6
  edit np6_0
    set per-session-accounting enable-by-log
  next
  edit np6_1
    set per-session-accounting enable-by-log
  end
```

If your FortiGate has NP6lite processors, you can use the following command to enable per-session accounting for all of the NP6lite processors in the FortiGate unit:

```
config system npu
  set per-session-accounting enable-by-log
end
```

The option, `enable-by-log` enables per-session accounting for offloaded sessions with traffic logging enabled and `all-enable` enables per-session accounting for all offloaded sessions.

By default, `per-session-accounting` is set to `enable-by-log`, which results in per-session accounting being turned on when you enable traffic logging in a policy.

Per-session accounting can affect offloading performance. So you should only enable per-session accounting if you need the accounting information.

Enabling per-session accounting does not provide traffic flow data for sFlow or NetFlow.

Configuring NP6 session timeouts

For NP6 traffic, FortiOS refreshes an NP6 session's lifetime when it receives a session update message from the NP6 processor. To avoid session update message congestion, these NP6 session checks are performed all at once after a random time interval and all of the update messages are sent from the NP6 processor to FortiOS at once. This can result in fewer messages being sent because they are only sent at random time intervals instead of every time a session times out.

In fact, if your NP6 processor is processing a lot of short lived sessions, it is recommended that you use the default setting of random checking every 8 seconds to avoid very bursty session updates. If the time between session updates is very long and very many sessions have been expired between updates a large number of updates will need to be done all at once.

You can use the following command to set the random time range.

```
config system np6
  edit <np6-processor-name>
    set session-timeout-fixed disable
    set session-timeout-random-range 8
  end
```

This is the default configuration. The random timeout range is 1 to 1000 seconds and the default range is 8. So, by default, NP6 sessions are checked at random time intervals of between 1 and 8 seconds. So sessions can be inactive for up to 8 seconds before they are removed from the FortiOS session table.

If you want to reduce the amount of checking you can increase the `session-timeout-random-range`. This could result in inactive sessions being kept in the session table longer. But if most of your NP6 sessions are relatively long this shouldn't be a problem.

You can also change this session checking to a fixed time interval and set a fixed timeout:

```
config system np6
  edit <np6-processor-name>
    set session-timeout-fixed enable
    set session-timeout-fixed 40
  end
```

The fixed timeout default is every 40 seconds and the range is 1 to 1000 seconds. Using a fixed interval further reduces the amount of checking that occurs.

You can select random or fixed updates and adjust the time intervals to minimize the refreshing that occurs while still making sure inactive sessions are deleted regularly. For example, if an NP6 processor is processing sessions with long lifetimes you can reduce checking by setting a relatively long fixed timeout.

Configure the number of IPsec engines NP6 processors use

NP6 processors use multiple IPsec engines to accelerate IPsec encryption and decryption. In some cases out of order ESP packets can cause problems if multiple IPsec engines are running. To resolve this problem you can configure all of the NP6 processors to use fewer IPsec engines.

Use the following command to change the number of IPsec engines used for decryption (`ipsec-dec-subengine-mask`) and encryption (`ipsec-enc-subengine-mask`). These settings are applied to all of the NP6 processors in the FortiGate unit.

```
config system npu
    set ipsec-dec-subengine-mask <engine-mask>
    set ipsec-enc-subengine-mask <engine-mask>
end
```

`<engine-mask>` is a hexadecimal number in the range 0x01 to 0xff where each bit represents one IPsec engine. The default `<engine-mask>` for both options is 0xff which means all IPsec engines are used. Add a lower `<engine-mask>` to use fewer engines. You can configure different engine masks for encryption and decryption.

Stripping clear text padding and IPsec session ESP padding

In some situations, when clear text or ESP packets in IPsec sessions may have large amounts of layer 2 padding, the NP6 IPsec engine may not be able to process them and the session may be blocked.

If you notice dropped IPsec sessions, you could try using the following CLI options to cause the NP6 processor to strip clear text padding and ESP padding before send the packets to the IPsec engine. With padding stripped, the session can be processed normally by the IPsec engine.

Use the following command to strip ESP padding:

```
config system npu
    set strip-esp-padding enable
    set strip-clear-text-padding enable
end
```

Stripping clear text and ESP padding are both disabled by default.

Disable NP6 CAPWAP offloading

By default and where possible, managed FortiAP and FortiLink CAPWAP sessions are offloaded to NP6 processors. You can use the following command to disable CAWAP session offloading:

```
config system npu
    set capwap-offload disable
end
```

Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces

Due to NP6 internal packet buffer limitations, some offloaded packets received at a 10Gbps interface and destined for a 1Gbps interface can be dropped, reducing performance for TCP and IP tunnel traffic. If you experience this performance reduction, you can use the following command to disable offloading sessions passing from 10Gbps interfaces to 1Gbps interfaces:

```
config system npu
    set host-shortcut-mode host-shortcut
```

end

Select `host-shortcut` to stop offloading TCP and IP tunnel packets passing from 10Gbps interfaces to 1Gbps interfaces. TCP and IP tunnel packets passing from 1Gbps interfaces to 10Gbps interfaces are still offloaded as normal.

If `host-shortcut` is set to the default `bi-directional` setting, packets in both directions are offloaded.

This option is only available if your FortiGate has 10G and 1G interfaces accelerated by NP6 processors.

Enabling bandwidth control between the ISF and NP6 XAUI ports

In some cases, the Internal Switch Fabric (ISF) buffer size may be larger than the buffer size of an NP6 XAUI port that receives traffic from the ISF. If this happens, burst traffic from the ISF may exceed the capacity of an XAUI port and sessions may be dropped.

You can use the following command to configure bandwidth control between the ISF and XAUI ports. Enabling bandwidth control can smooth burst traffic and keep the XAUI ports from getting overwhelmed and dropping sessions.

Use the following command to enable bandwidth control:

```
config system npu
  set sw-np-bandwidth {0G | 2G | 4G | 5G | 6G}
end
```

The default setting is `0G` which means no bandwidth control. The other options limit the bandwidth to 2Gbps, 4Gbps and so on.

NP6 session drift

In some cases, sessions processed by NP6 processors may fail to be deleted leading to a large number of idle sessions. This is called session drift. You can use SNMP to be alerted when the number of idle sessions becomes high. SNMP also allows you to see which NP6 processor has the abnormal number of idle sessions and you can use a `diagnose` command to delete them.

The following MIB fields allow you to use SNMP to monitor session table information for NP6 processors including drift for each NP6 processor:

```
FORTINET-FORTIGATE-MIB::fgNPUNumber.0 = INTEGER: 2
FORTINET-FORTIGATE-MIB::fgNPUName.0 = STRING: NP6
FORTINET-FORTIGATE-MIB::fgNPUDrvDriftSum.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIndex.1 = INTEGER: 1
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.0 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.1 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.0 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.1 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.1 = INTEGER: 0
```

You can also use the following `diagnose` command to determine if drift is occurring:

```
diagnose npu np6 sse-drift-summary
NPU   drv-drift
-----
np6_0 0
```

```
np6_1 0
-----
Sum    0
-----
```

The command output shows a drift summary for all the NP6 processors in the system, and shows the total drift. Normally the sum is 0. The previous command output, from a FortiGate-1500D, shows that the 1500D's two NP6 processors are not experiencing any drift.

If the sum is not zero, then extra idle sessions may be accumulating. You can use the following command to delete those sessions:

```
diagnose npu np6 sse-purge-drift <np6_id> [<time>]
```

Where **<np6_id>** is the number (starting with NP6_0 with a np6_id of 0) of the NP6 processor for which to delete idle sessions in. **<time>** is the age in seconds of the idle sessions to be deleted. All idle sessions this age and older are deleted. The default time is 300 seconds.

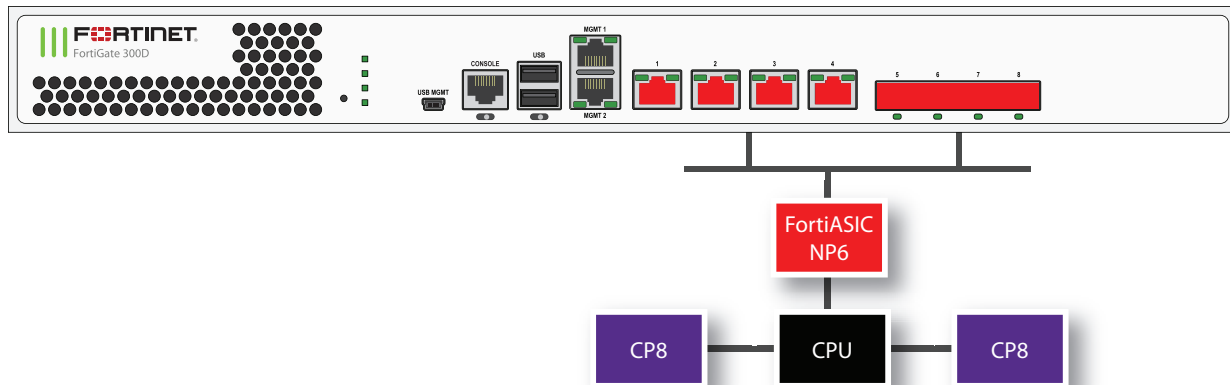

The `diagnose npu np6 sse-stats <np6_id>` command output also includes a `drv-drift` field that shows the total drift for one NP6 processor.

FortiGate NP6 architectures

This chapter shows the NP6 architecture for the all FortiGate models that include NP6 processors.

FortiGate-300D fast path architecture

The FortiGate-300D includes one NP6 processor connected to four 1Gb RJ-45 Ethernet ports (port1-4) and four 1Gb SFP interfaces (port5-port8).

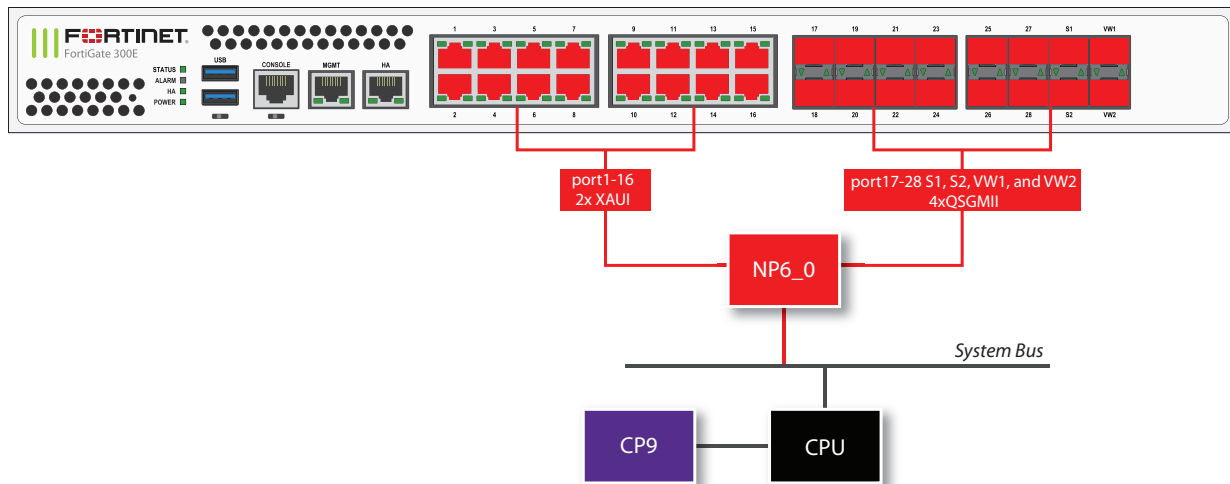

You can use the following `get` command to display the FortiGate-300D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
Chip  XAUI Ports  Max  Cross-chip
      Speed offloading
-----
np6_0  0
      1  port5  1G   Yes
      1  port7  1G   Yes
      1  port8  1G   Yes
      1  port6  1G   Yes
      1  port3  1G   Yes
      1  port4  1G   Yes
      1  port1  1G   Yes
      1  port2  1G   Yes
      2
      3

```

FortiGate-300E and 301E fast path architecture

The FortiGate-300E and 301E each include one NP6 processor. All front panel data interfaces (port1 to 28, S1, S2, VW1, and VW2) connect to the NP6 processor. So all supported traffic passing between any two data interfaces can be offloaded.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processor and the front panel interfaces.

You can use the following `get` command to display the FortiGate-300E or 301E NP6 configuration. You can also use the `diagnose npu np6 port-list` command to display this information.

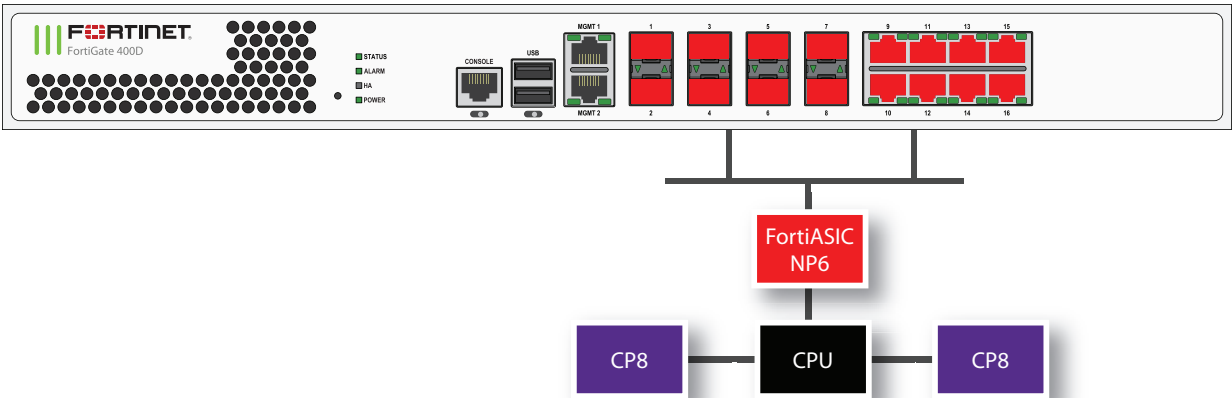

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading
np6_0	0	port1	1G	Yes

	3	s2	1G	Yes

3	vw1	1G	Yes
3	vw2	1G	Yes

FortiGate-400D fast path architecture

The FortiGate-400D includes one NP6 processor connected to eight 1Gb SFP interfaces (port1-port8) and eight 1Gb RJ-45 Ethernet ports (port9-16).

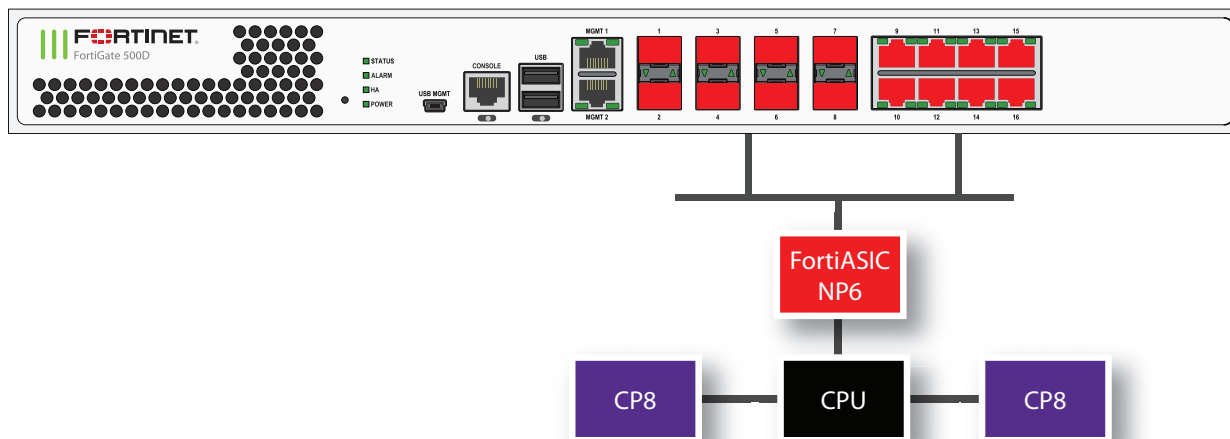

You can use the following get command to display the FortiGate-400D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list

FortiGate-500E and 501E fast path architecture

The FortiGate-500E and 501E each include one NP6 processor. All front panel data interfaces (port1 to 212, S1, S2, VW1, VW2, X1 and X2) connect to the NP6 processor. So all supported traffic passing between any two data

interfaces can be offloaded.

The following diagram also shows the QSGMII and XAUI port connections between the NP6 processor and the front panel interfaces.

You can use the following get command to display the FortiGate-500E or 501E NP6 configuration. You can also use the diagnose npu np6 port-list command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-800D fast path architecture

The FortiGate-800D includes one NP6 processor connected through an integrated switch fabric to all of the FortiGate-800D network interfaces. This hardware configuration supports NP6-accelerated fast path offloading for sessions between any of the FortiGate-800D interfaces.

You can use the following `get` command to display the FortiGate-800D NP6 configuration. The command output shows one NP6 named NP6_0. The output also shows all of the FortiGate-800D interfaces (ports) connected to NP6_0. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

	3	port32	10G	Yes

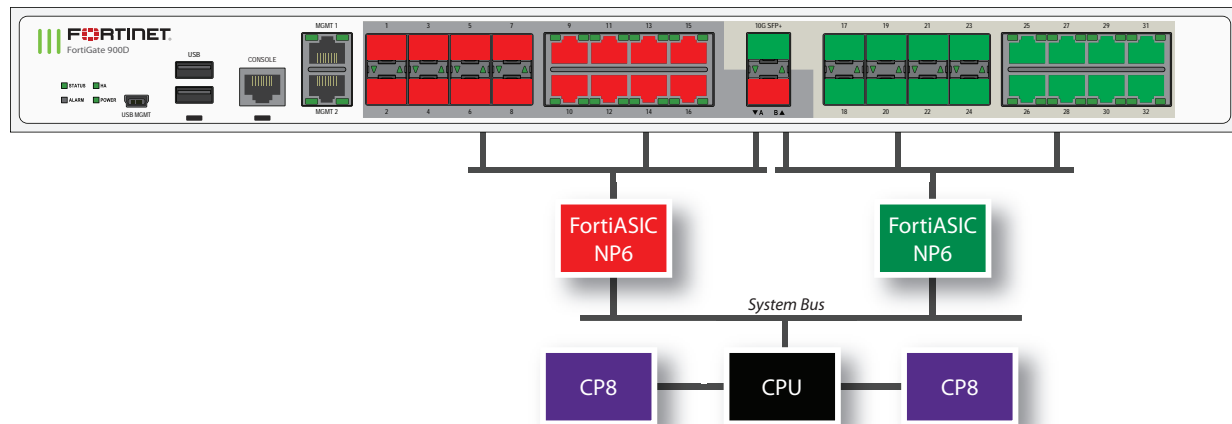

FortiGate-900D fast path architecture

The FortiGate-900D includes two NP6 processors that are not connected by an integrated switch fabric (ISF). Without an ISF, traffic through a FortiGate-900D could experience lower latency than traffic through similar hardware with an ISF. The NP6 processors are connected to network interfaces as follows:

Because the FortiGate-900D does not have an ISF you cannot create Link Aggregation Groups (LAGs) that include interfaces connected to both NP6 processors.

- Eight 1Gb SFP interfaces (port17-port24), eight 1Gb RJ-45 Ethernet interfaces (port25-32) and one 10Gb SFP+ interface (portB) share connections to the first NP6 processor.
- Eight 1Gb SFP interfaces (port1-port8), eight RJ-45 Ethernet interfaces (port9-16) and one 10Gb SFP+ interface (portA) share connections to the second NP6 processor.

You can use the following get command to display the FortiGate-900D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```

get hardware npu np6 port-list

FortiGate-1000D fast path architecture

The FortiGate-1000D includes two NP6 processors that are not connected by an integrated switch fabric (ISF). The NP6 processors are connected to network interfaces as follows:

Because the FortiGate-1000D does not have an ISF you cannot create Link Aggregation Groups (LAGs) or redundant interfaces that include interfaces connected to both NP6 processors.

- Eight 1Gb SFP interfaces (port17-port24), eight 1Gb RJ-45 Ethernet interfaces (port25-32) and one 10Gb SFP+ interface (portB) share connections to the first NP6 processor.
- Eight 1Gb SFP interfaces (port1-port8), eight RJ-45 Ethernet interfaces (port9-16) and one 10Gb SFP+ interface (portA) share connections to the second NP6 processor.

You can use the following `get` command to display the FortiGate-1000D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```

FortiGate-1500DT fast path architecture

The FortiGate-1500DT features two NP6 processors both connected to an integrated switch fabric. The FortiGate-1500DT has the same hardware configuration as the FortiGate-1500D, but with the addition of newer CPUs and a slightly different interface configuration.

The FortiGate-1500DT includes the following interfaces and NP6 processors:

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 1Gb Ethernet interfaces (port17-24) and four RJ-45 10Gb Ethernet interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 1Gb Ethernet ports (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.

You can use the following get command to display the FortiGate-1500DT NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-2000E fast path architecture

The FortiGate-2000E includes three NP6 processors in an NP Direct configuration. The NP6 processors connected to the 10GigE ports are also in a low latency NP Direct configuration. Because of NP Direct, you cannot create Link Aggregation Groups (LAGs) or redundant interfaces between interfaces connected to different NP6s. As well, traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to four 10GigE SFP+ interfaces (port33 to port36) in a low latency configuration.
- NP6_1 is connected to thirty-two 10/100/1000BASE-T interfaces (port1 to port32).
- NP6_2 is connected to two 10GigE SFP+ (port37 and port38) in a low latency configuration.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processors and the front panel interfaces and the aggregate switch for the thirty-two 10/100/1000BASE-T interfaces.

You can use the following get command to display the FortiGate-2000E NP6 configuration. You can also use the diagnose npu np6 port-list command to display this information.

```

get hardware npu np6 port-list
Chip    XAUI Ports    Max    Cross-chip

FortiGate-2500E fast path architecture

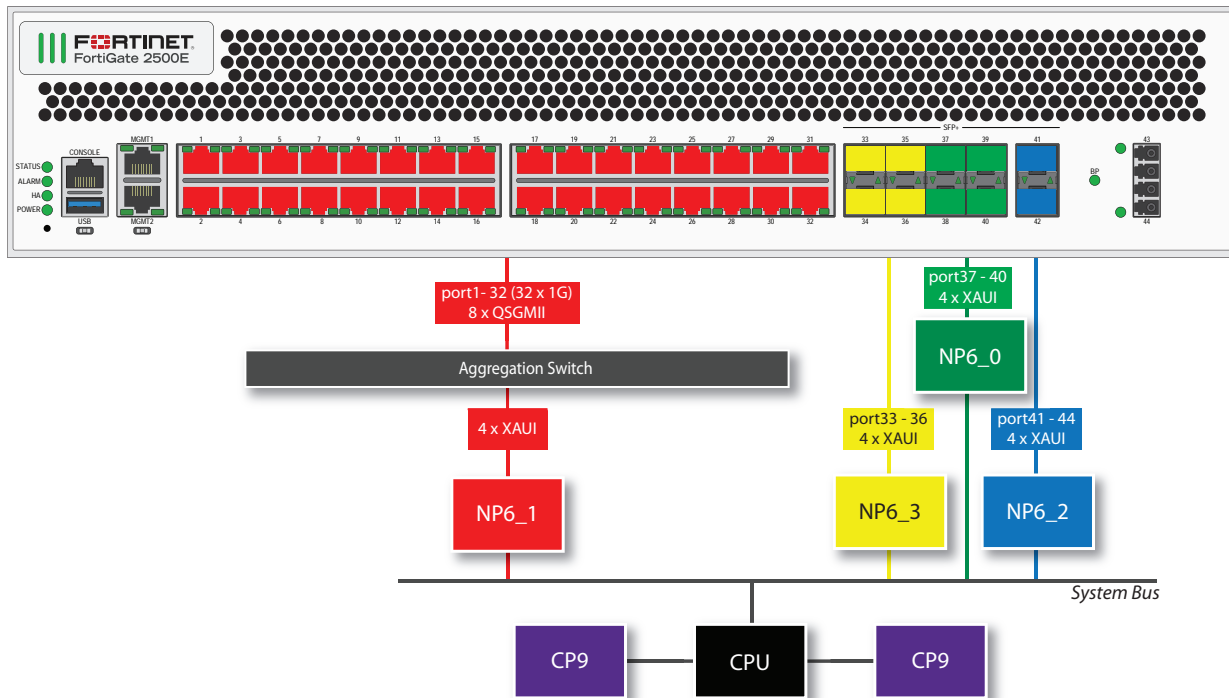

The FortiGate-2500E includes four NP6 processors in an NP Direct configuration. The NP6 processors connected to the 10GigE ports are also in a low latency NP Direct configuration. Because of NP Direct, you cannot create

Link Aggregation Groups (LAGs) or redundant interfaces between interfaces connected to different NP6s. As well, traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to four 10GigE SFP+ interfaces (port37 to port40) in a low latency configuration.
- NP6_1 is connected to thirty-two 10/100/1000BASE-T interfaces (port1 to port32).
- NP6_2 is connected to two 10GigE SFP+ interfaces (port41 and port42) and two 10 Gig fiber bypass interfaces (port43 and port44) in a low latency configuration.
- NP6_3 is connected to four 10GigE SFP+ interfaces (port33 to port36) in a low latency configuration.

The following diagram also shows the XAUI and QSGMII port connections between the NP6 processors and the front panel interfaces and the aggregate switch for the thirty-two 10/100/1000BASE-T interfaces.

You can use the following get command to display the FortiGate-2500E NP6 configuration. You can also use the diagnose npu np6 port-list command to display this information.

```

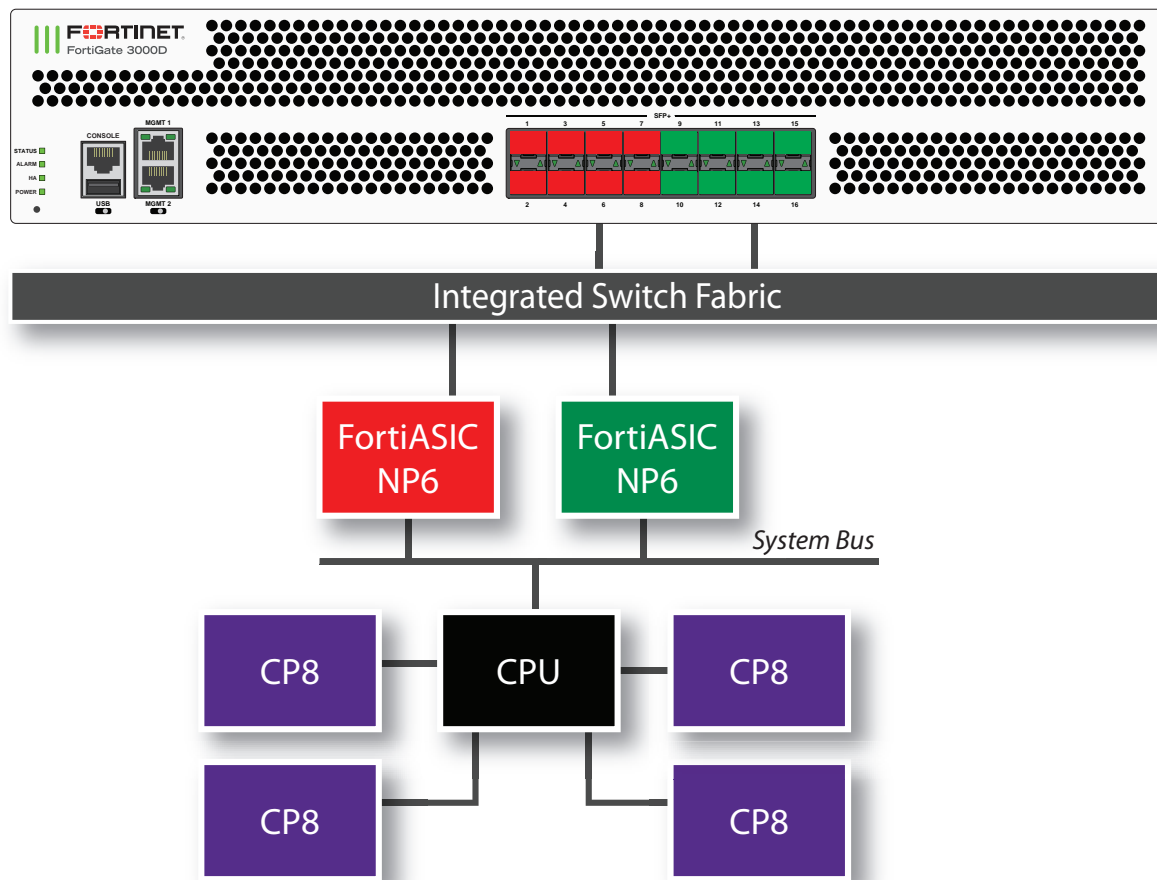

get hardware npu np6 port-list

FortiGate-3000D fast path architecture

The FortiGate-3000D features 16 front panel SFP+ 10Gb interfaces connected to two NP6 processors through an Integrated Switch Fabric (ISF). The FortiGate-3000D has the following fastpath architecture:

- 8 SFP+ 10Gb interfaces, port1 through port8 share connections to the first NP6 processor (np6_0).
- 8 SFP+ 10Gb interfaces, port9 through port16 share connections to the second NP6 processor (np6_1).

You can use the following get command to display the FortiGate-3000D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1 and the interfaces (ports) connected to each NP6. You can also use the diagnose npu np6 port-list command to display this information.

```
get hardware npu np6 port-list
```

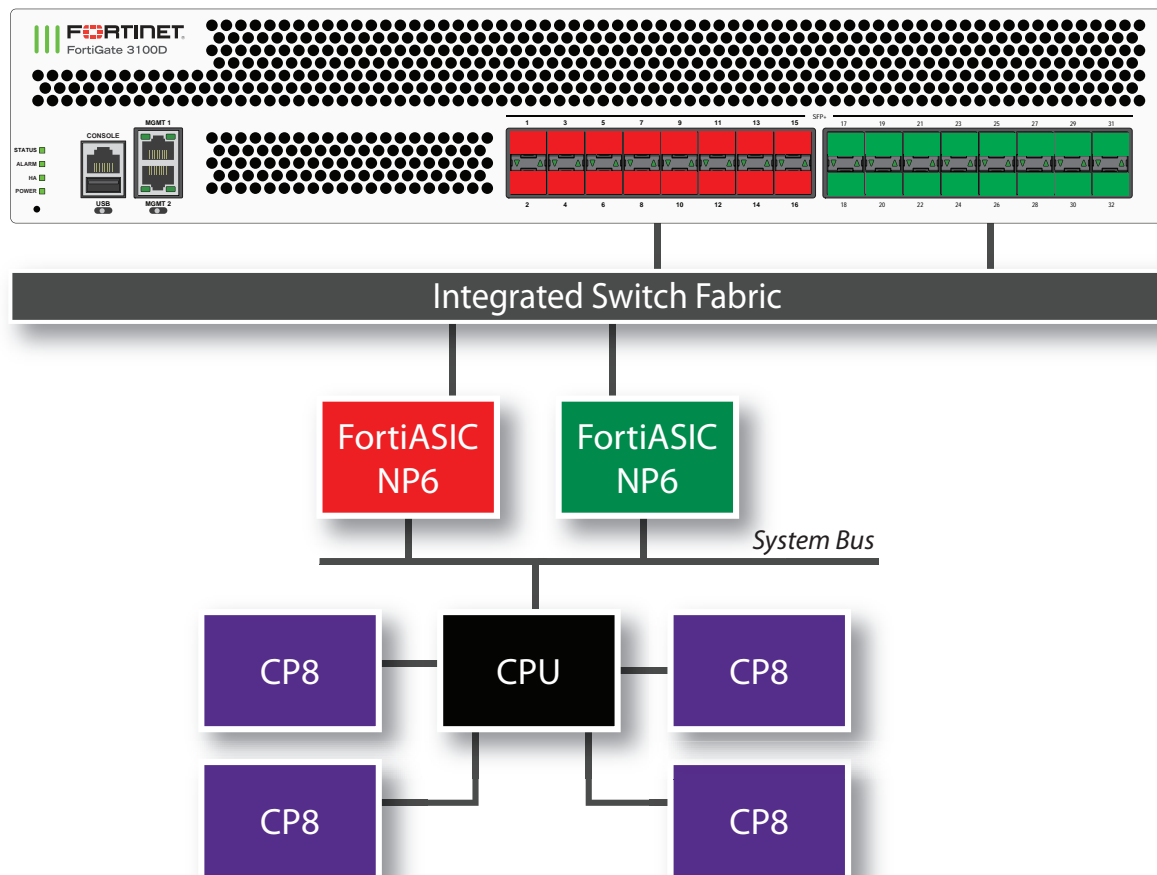

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

FortiGate-3700D fast path architecture

The FortiGate-3700D features four NP6 processors. The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700D fast path architecture.

FortiGate-3700D low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency than other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

You can use the following command to turn on low latency mode for np6_0 and np6_1:

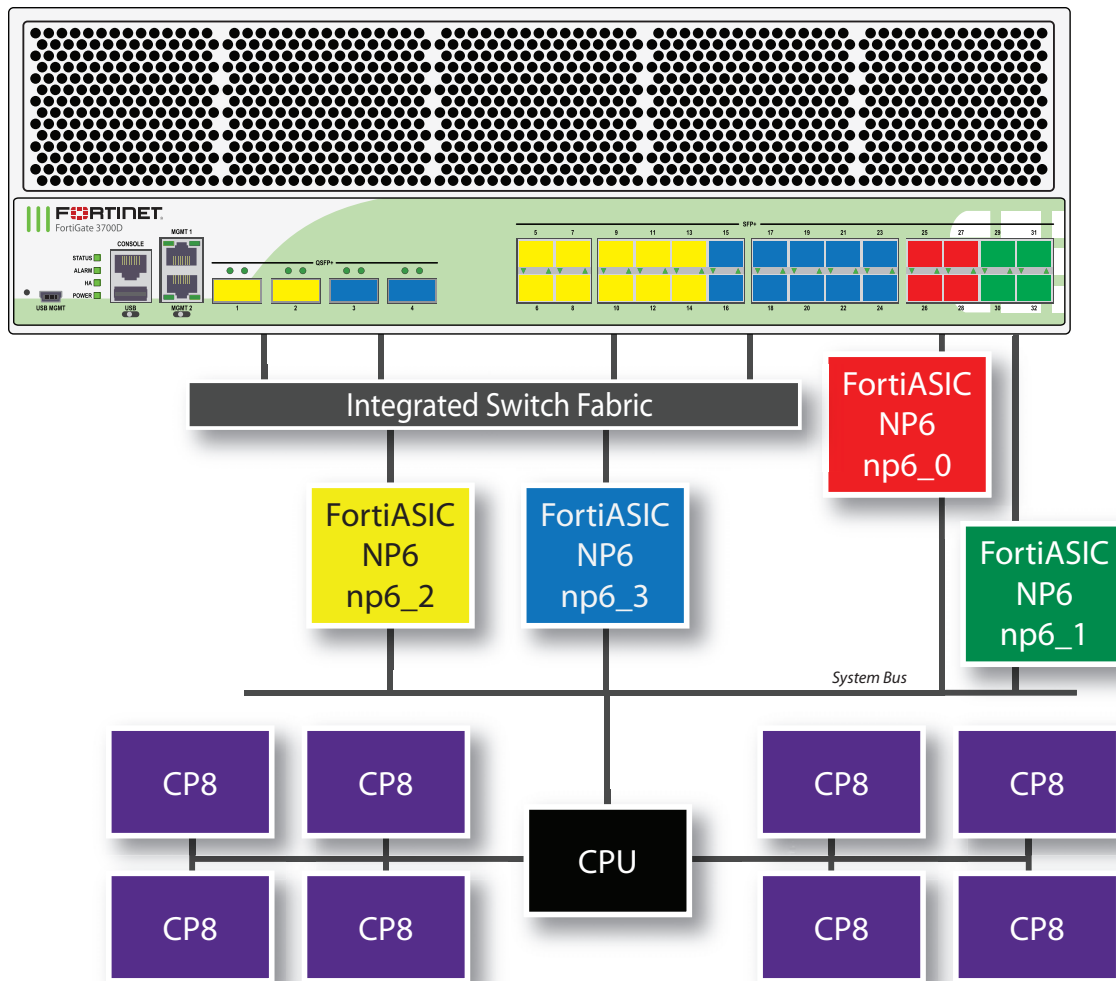

```
config system np6
  edit np6_0
    set low-latency-mode enable
  next
  edit np6_1
    set low-latency-mode enable
end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700D has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
Chip  XAUI Ports  Max  Cross-chip
      Speed    offloading
-----
np6_2  0      port5    10G  Yes
      0      port9    10G  Yes
      0      port13   10G  Yes
      1      port6    10G  Yes
      1      port10   10G  Yes
      1      port14   10G  Yes
      2      port7    10G  Yes
      2      port11   10G  Yes
      3      port8    10G  Yes
      3      port12   10G  Yes
      0-3    port1    40G  Yes
```

	0-3	port2	40G	Yes

np6_3	0	port15	10G	Yes
	0	port19	10G	Yes
	0	port23	10G	Yes
	1	port16	10G	Yes
	1	port20	10G	Yes
	1	port24	10G	Yes
	2	port17	10G	Yes
	2	port21	10G	Yes
	3	port18	10G	Yes
	3	port22	10G	Yes
	0-3	port3	40G	Yes
	0-3	port4	40G	Yes

np6_0	0	port26	10G	No
	1	port25	10G	No
	2	port28	10G	No
	3	port27	10G	No

np6_1	0	port30	10G	No
	1	port29	10G	No
	2	port32	10G	No
	3	port31	10G	No

FortiGate-3700D normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

```
config system np6
edit np6_0
set low-latency-mode disable
next
edit np6_1
set low-latency-mode disable
end
```

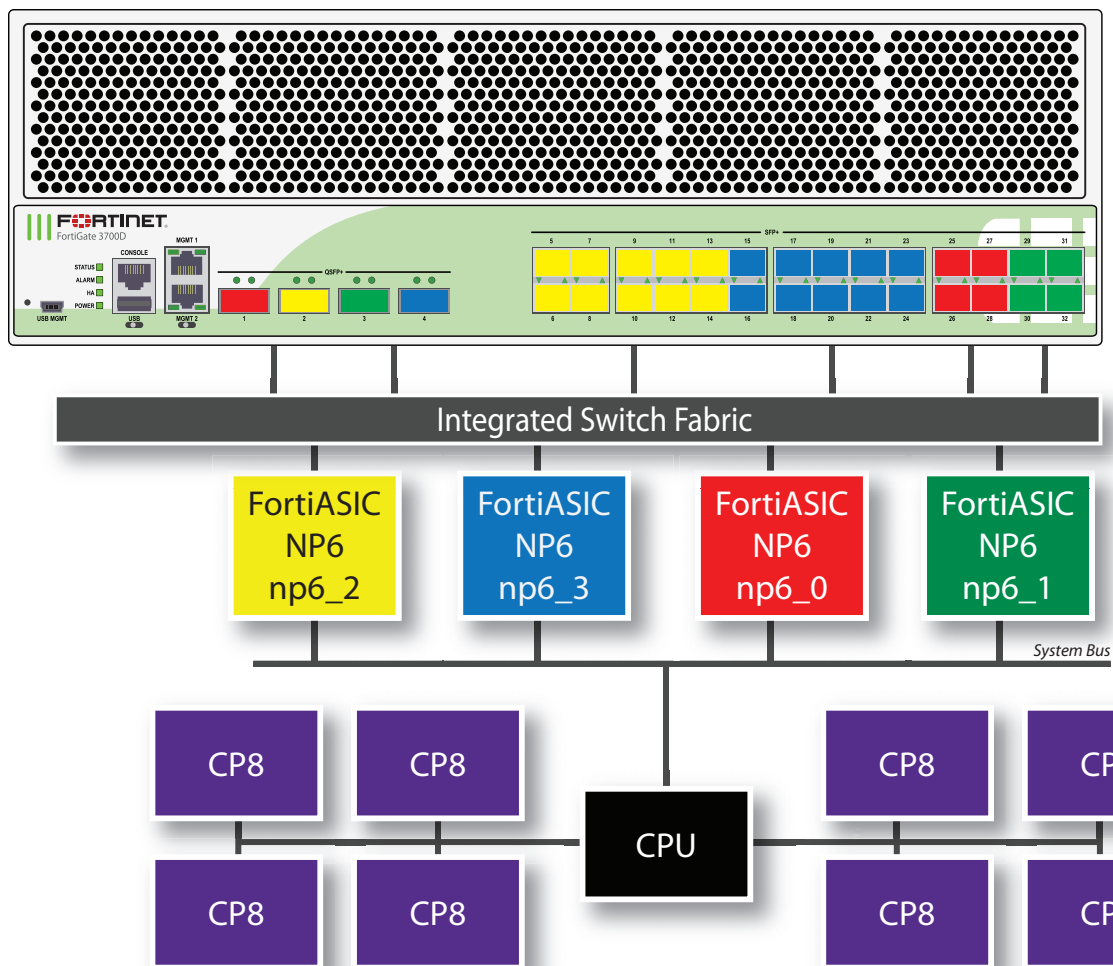

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700D has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).

- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-3700DX fast path architecture

The FortiGate-3700DX features four NP6 processors. The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700D fast path architecture. The FortiGate-3700DX also includes two TP2 cards that offload GTPu sessions.

FortiGate-3700DX low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency than other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

You can use the following command to turn on low latency mode for np6_0 and np6_1:

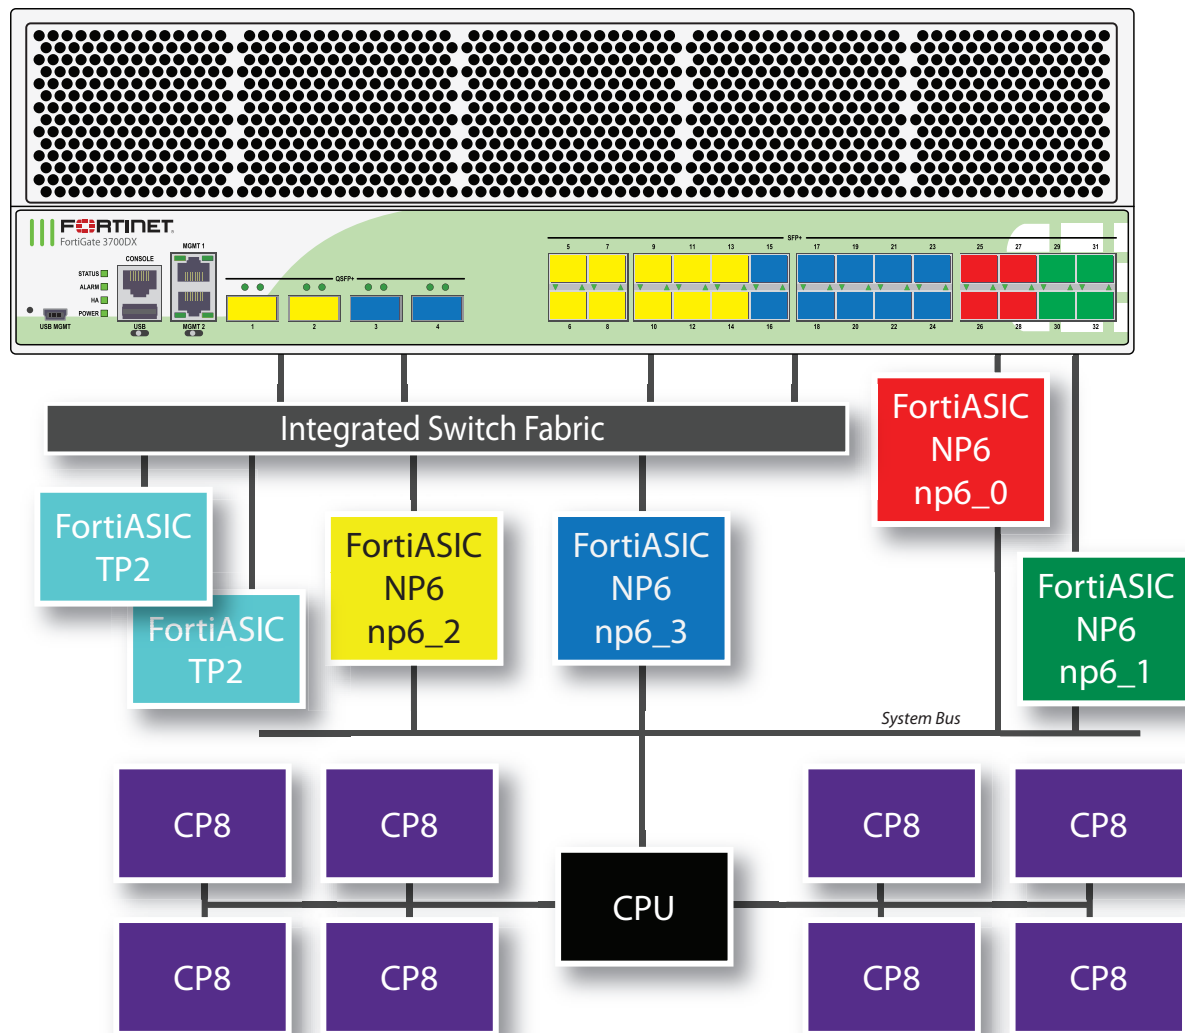

```
config system np6
  edit np6_0
    set low-latency-mode enable
  next
  edit np6_1
    set low-latency-mode enable
end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700D has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four

NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

np6_2	0	port5	10G	Yes
	0	port9	10G	Yes
	0	port13	10G	Yes
	1	port6	10G	Yes
	1	port10	10G	Yes
	1	port14	10G	Yes
	2	port7	10G	Yes
	2	port11	10G	Yes
	3	port8	10G	Yes
	3	port12	10G	Yes
	0-3	port1	40G	Yes
	0-3	port2	40G	Yes

np6_3	0	port15	10G	Yes
	0	port19	10G	Yes
	0	port23	10G	Yes
	1	port16	10G	Yes
	1	port20	10G	Yes
	1	port24	10G	Yes
	2	port17	10G	Yes
	2	port21	10G	Yes
	3	port18	10G	Yes
	3	port22	10G	Yes
	0-3	port3	40G	Yes
	0-3	port4	40G	Yes

np6_0	0	port26	10G	No
	1	port25	10G	No
	2	port28	10G	No
	3	port27	10G	No

np6_1	0	port30	10G	No
	1	port29	10G	No
	2	port32	10G	No
	3	port31	10G	No

FortiGate-3700D normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

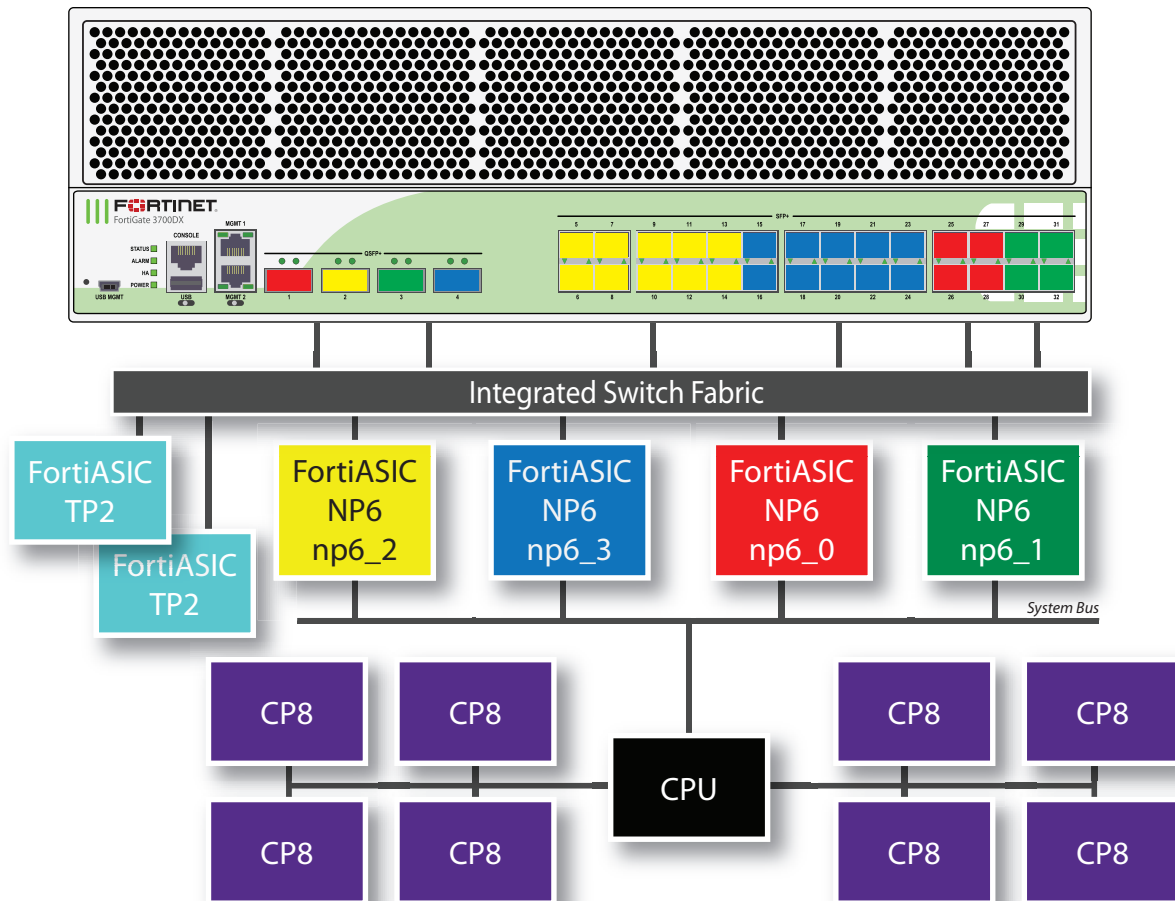

```
config system np6
  edit np6_0
    set low-latency-mode disable
  next
  edit np6_1
    set low-latency-mode disable
end
```

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700D has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).
- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).

You can use the following get command to display the FortiGate-3700D NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-3800D fast path architecture

The FortiGate-3800D features four front panel 100GigE CFP2 interfaces, four 40GigE QSFP+ interfaces, and eight 10GigE SFP+ interfaces connected to eight NP6 processors through an Integrated Switch Fabric (ISF). Individual interfaces are not mapped to NP6 processors because of the integrated switch fabric. No special mapping is required for fastpath offloading or aggregate interfaces.

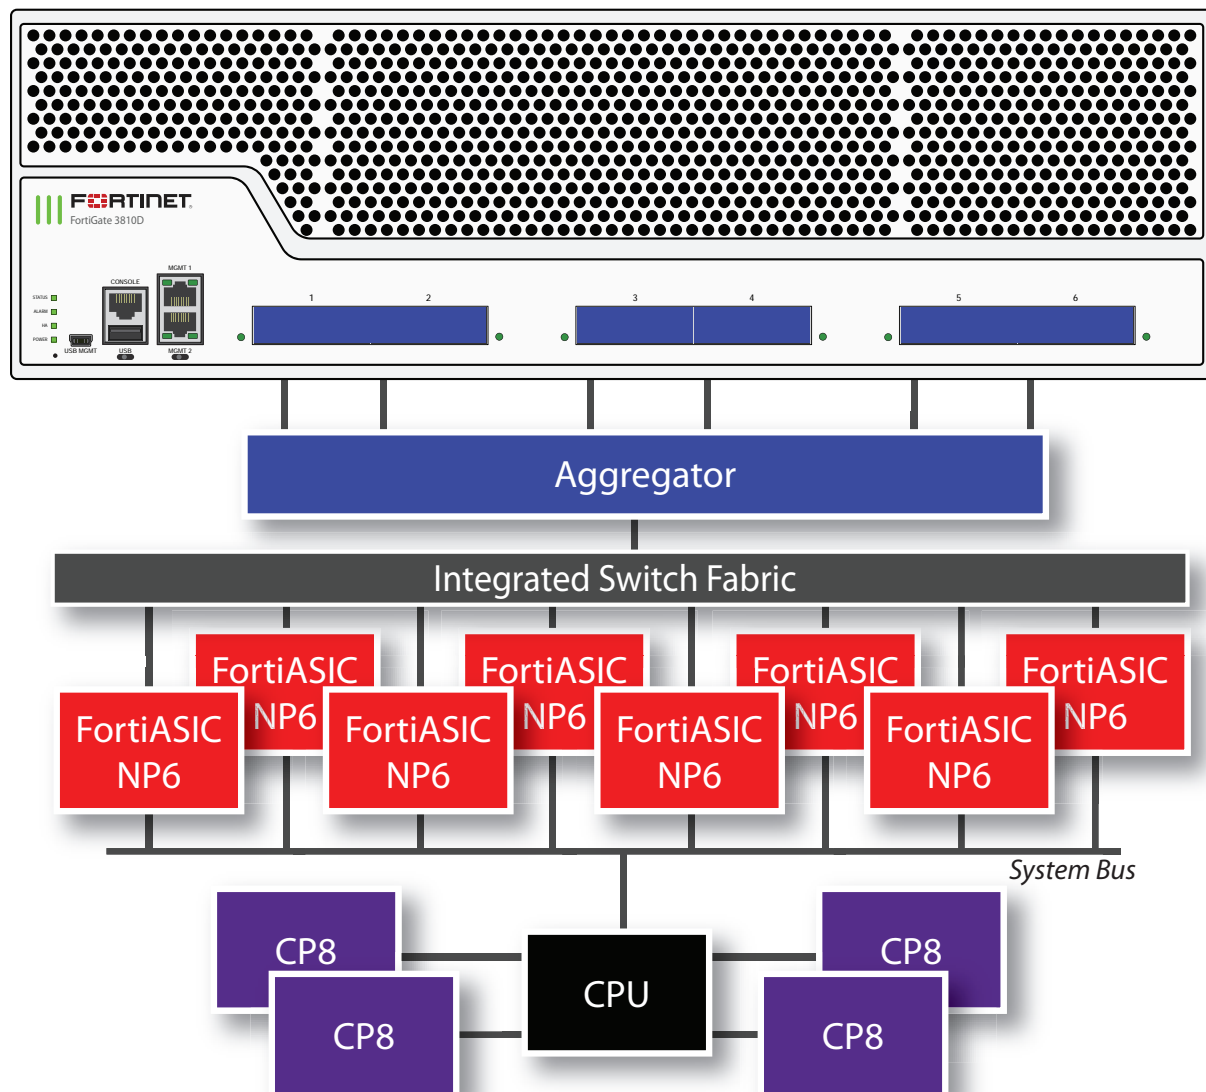

You can use the following get command to display the FortiGate-3800D NP6 configuration. The command output shows all NP6s connected to each interface (port) with cross-chip offloading supported for each port. You can also use the diagnose npu np6 port-list command to display this information.

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

FortiGate-5001E and 5001E1 fast path architecture

The FortiGate-5001E and 5001E1 features two NP6 processors and an integrated switch fabric. The integrated switch fabric allows you to configure aggregate interfaces between interfaces connected to different NP6s and supports offloading between for traffic entering and exiting from any interfaces.

The NP6s are connected to network interfaces as follows:

- NP6_0 is connected to port1, port3, fabric1, and base1.
- NP6_1 is connected to port2, port4, fabric2, and base2.

The following diagram also shows the XAUI port connections between the NP6 processors and the front panel interfaces and the integrated switch fabric.

NP6 default interface mapping

You can use the following get command to display the FortiGate-5001E NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

Chip	XAUI	Ports	Max Speed	Cross-chip offloading
np6_0	0	port3	10G	Yes
	1			
	2	base1	1G	Yes
	3			
	0-3	port1	40G	Yes

```

FortiController-5902D fast path architecture

The FortiController-5902D NP6 network processors and integrated switch fabric (ISF) provide hardware acceleration by offloading load balancing from the primary FortiController-5902D CPU. Network processors are especially useful for accelerating load balancing of TCP and UDP sessions.

The first packet of every new session is received by the primary FortiController-5902D and the primary FortiController-5902D uses its load balancing schedule to select the worker that will process the new session. This information is passed back to an NP6 network processor and all subsequent packets of the same sessions are offloaded to an NP6 network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the NP6 network processors resulting in a faster and more stable active-active cluster.

Traffic accepted by the FortiController-5902D F1 to F4 interfaces is that is processed by the primary FortiController-5902D is also be offloaded to the NP6 processors.

Individual FortiController-5902D interfaces are not mapped to NP6 processors. Instead an Aggregator connects the all fabric interfaces to the ISF and no special mapping is required for fastpath offloading.

NP6 content clustering mode interface mapping

FortiController-5902Ds run in content clustering mode and load balance sessions to FortiGate-5001D workers. Use the following command to enable content clustering:

```

config system elbc
    set mode content-cluster
    set inter-chassis-support enable
end

```

You can use the following get command to display the content clustering FortiController-5902D NP6 configuration. The output shows that all ports are mapped to all NP6 processors. You can also use the `diagnose npu np6 port-list` command to display this information.

```
get hardware npu np6 port-list
```

FortiGate-6000 series

The FortiGate-6000 series includes the FortiGate-6300F, 6301F, 6500F, and 6501F. All of these models have the same hardware architecture. FortiGate-6000 models have separate data and management planes. The data plane handles all traffic and security processing functionality. The management plane handles management functions such as administrator logins, configuration and session synchronization, SNMP and other monitoring, HA heartbeat communication, and remote and (if supported) local disk logging. Separating these two planes means that resources used for traffic and security processing are not compromised by management activities.

FortiGate-6000 schematic

In the data plane, two DP3 load balancers use session-aware load balancing to distribute sessions from the front panel interfaces (port1 to 28) to Fortinet Processor Cards (FPCs). The DP3 processors communicate with the FPCs across the 3.2Tbps integrated switch fabric. Each FPC processes sessions load balanced to it. The FPCs send outgoing sessions back to the integrated switch fabric and then out the network interfaces to their destinations.

The NP6 processor in each FPC enhances network performance with fastpath acceleration that offloads communication sessions from the FPC CPU. The NP6 processor can also handle some CPU intensive tasks, like IPsec VPN encryption/decryption. The NP6 processor in each FPC connects to the integrated switch fabric over four XAUI ports.

The CP9 processors in each FPC accelerate many common resource intensive security related processes such as SSL VPN, Antivirus, Application Control, and IPS.

The management plane includes the management board, base backplane, management interfaces, and HA heartbeat interfaces. Configuration and session synchronization between FPCs in a FortiGate-6000F occurs over the base backplane. In an HA configuration, configuration and session synchronization between the FortiGate-6000s in the cluster takes place over the HA1 and HA2 interfaces. Administrator logins, SNMP monitoring, remote logging to one or more FortiAnalyzers or syslog servers, and other management functions use the MGMT1, MGMT2, and MGMT3 interfaces. You can use the 10Gbps MGMT3 interface for additional bandwidth that might be useful for high bandwidth activities such as remote logging.

From the management board, you can use the `diagnose npu np6 port-list` command to display the FortiGate-6000 NP6 configuration. The command output shows the NP6 configuration for all of the FPCs. You can see the same information for individual FPCs by logging into each FPC (for example by using the `execute system console-server connect <slot-number>` command) and using the same `diagnose` command or the `get hardware npu np6 port-list` command.

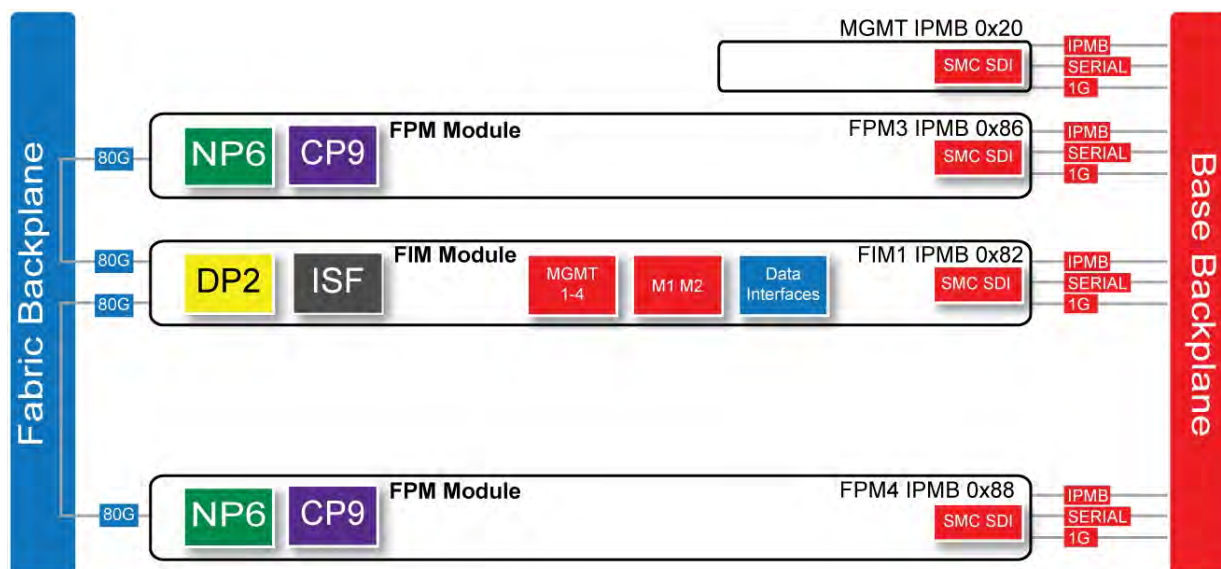

As shown in the example below for the FPC in slot 1, all of the FortiGate-6000 front panel interfaces and the fabric backplane (elbc-ctrl) connect to the NP6 processor in each FPC.

```
diagnose npu np6 port-list

FortiGate-7030E fast path architecture

The FortiGate-7030E chassis schematic below shows the communication channels between chassis components including the management module (MGMT), the FIM (called FIM1) and the FPMs (FPM3 and FPM4).

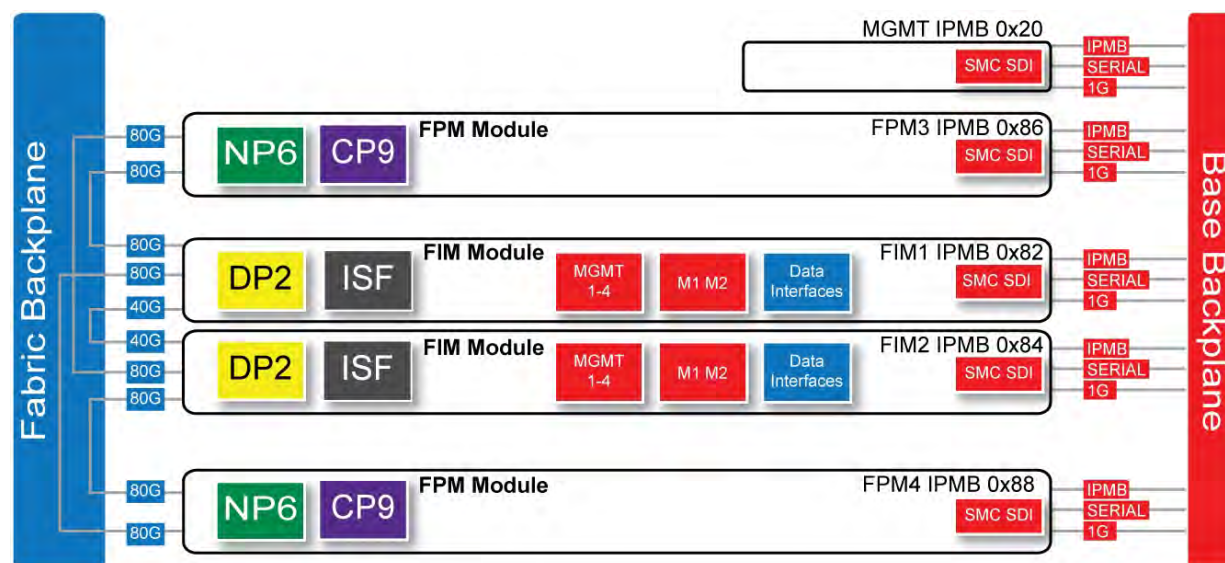

The management module (MGMT, with Intelligent Platform Management Bus (IPMB) address 0x20) communicates with all modules in the chassis over the base backplane. Each module, including the management module includes a Shelf Management Controller (SMC). These SMCs support IPMB communication between the management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 (IPMB address 0x82) is the FIM in slot 1. The interfaces of this module connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIM includes DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

FPM3 and FPM4 (IPMB addresses 0x86 and 0x88) are the FPM processor modules in slots 3 and 4. These worker modules process sessions distributed to them by the FIM. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

FortiGate-7040E fast path architecture

The FortiGate-7040E chassis schematic below shows the communication channels between chassis components including the management module (MGMT), the FIMs (called FIM1 and FIM2) and the FPMs (FPM3 and FPM4).

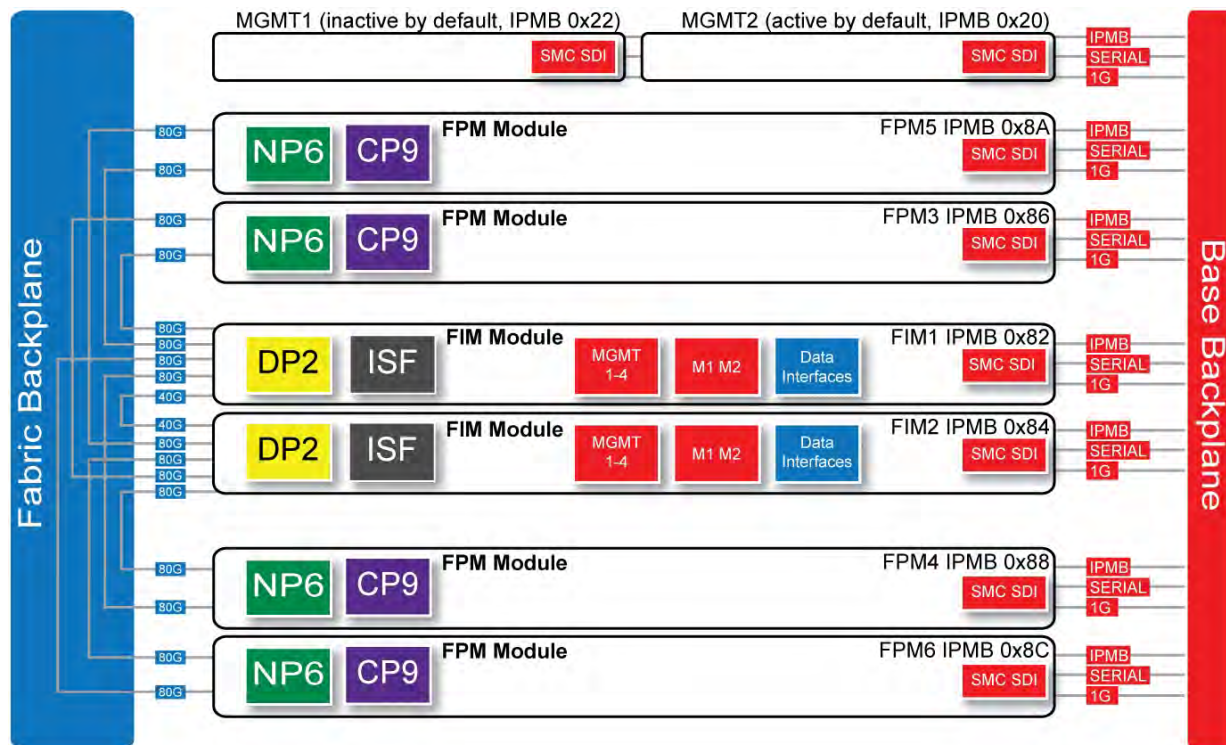

The management module (MGMT, with Intelligent Platform Management Bus (IPMB) address 0x20) communicates with all modules in the chassis over the base backplane. Each module, including the management module, includes a Shelf Management Controller (SMC). These SMCs support IPMB communication between the management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 and FIM2 (IPMB addresses 0x82 and 0x84) are the FIMs in slots 1 and 2. The interfaces of these modules connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIMs include DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

FPM3 and FPM4 (IPMB addresses 0x86 and 0x88) are the FPM processor modules in slots 3 and 4. These worker modules process sessions distributed to them by the FIMs. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

FortiGate-7060E fast path architecture

The FortiGate-7060E chassis schematic below shows the communication channels between chassis components including the management modules (MGMT), the FIMs (called FIM1 and FIM2) and the FPMs (FPM3, FPM4, FPM5, and FPM6).

By default, MGMT2 is the active management module and MGMT1 is inactive. The active management module always has the Intelligent Platform Management Bus (IPMB) address 0x20 and the inactive management module always has the IPMB address 0x22.

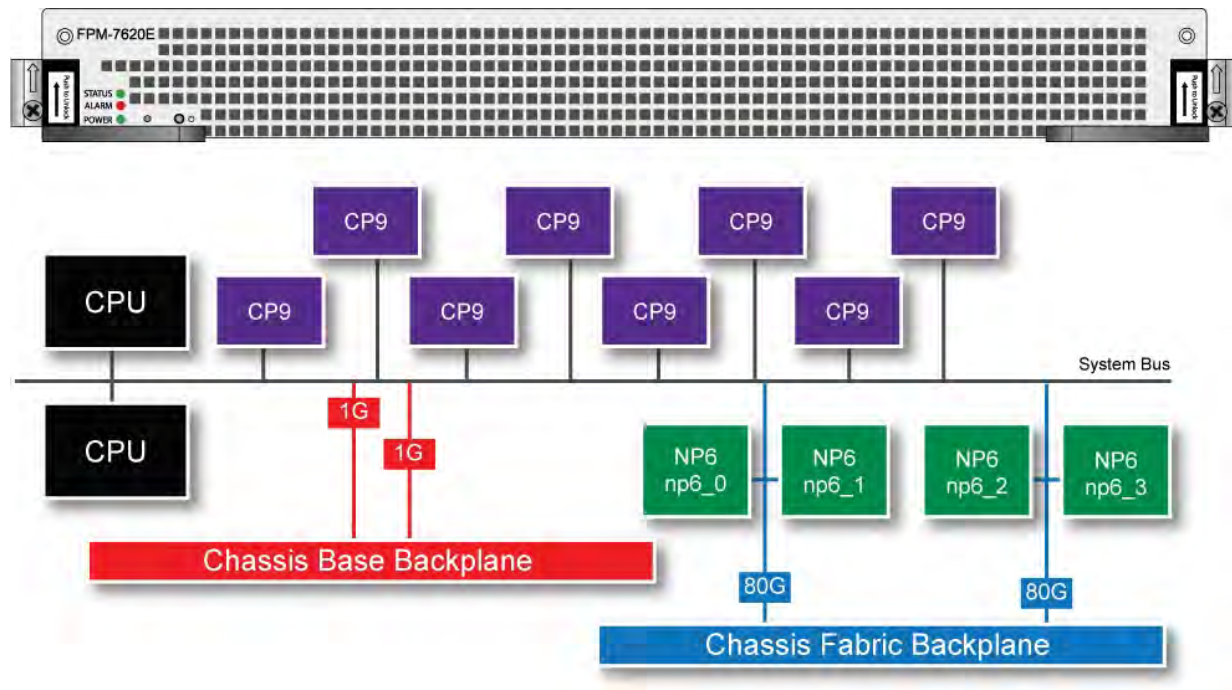

The active management module communicates with all modules in the chassis over the base backplane. Each module, including the management modules has a Shelf Management Controller (SMC). These SMCs support IPMB communication between the active management module and the FIM and FPMs for storing and sharing sensor data that the management module uses to control chassis cooling and power distribution. The base backplane also supports serial communications to allow console access from the management module to all modules, and 1Gbps Ethernet communication for management and heartbeat communication between modules.

FIM1 and FIM2 (IPMB addresses 0x82 and 0x84) are the FIMs in slots 1 and 2. The interfaces of these modules connect the chassis to data networks and can be used for Ethernet management access to chassis components. The FIMs include DP2 processors that distribute sessions over the Integrated Switch Fabric (ISF) to the NP6 processors in the FPMs. Data sessions are communicated to the FPMs over the 80Gbps chassis fabric backplane.

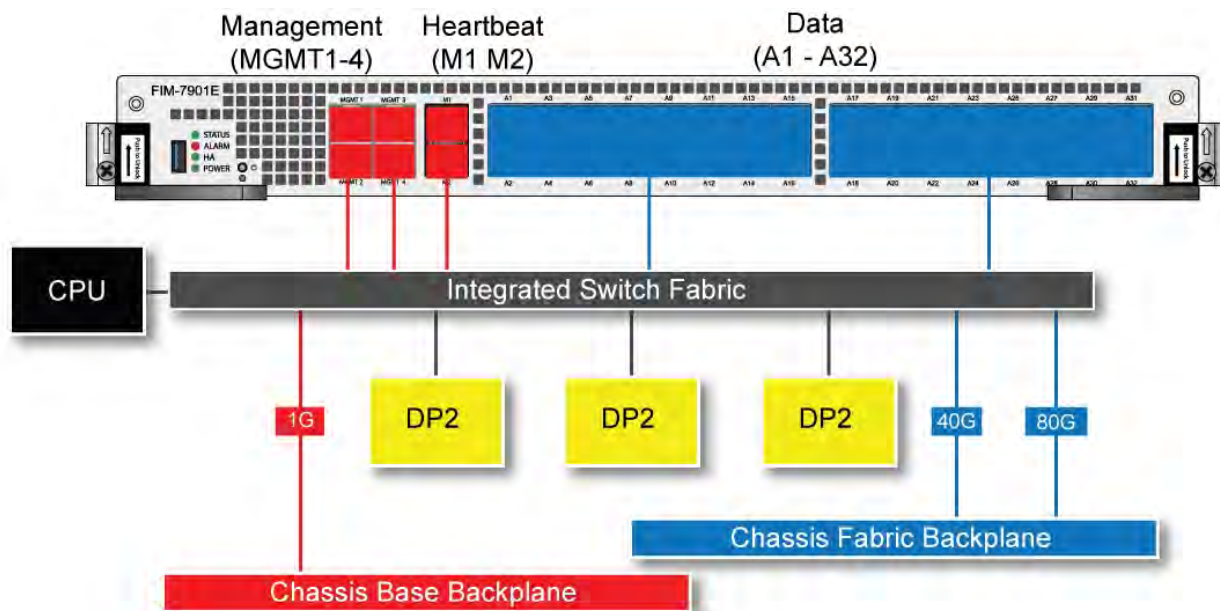

FPM03, FPM04, FPM05, and FPM06 (IPMB addresses 0x86, 0x88, 0x8A, and 0x8C) are the FPM processor modules in slots 3 to 6. These worker modules process sessions distributed to them by the FIMs. FPMs include NP6 processors to offload sessions from the FPM CPU and CP9 processors that accelerate content processing.

FPM-7620E fast path architecture

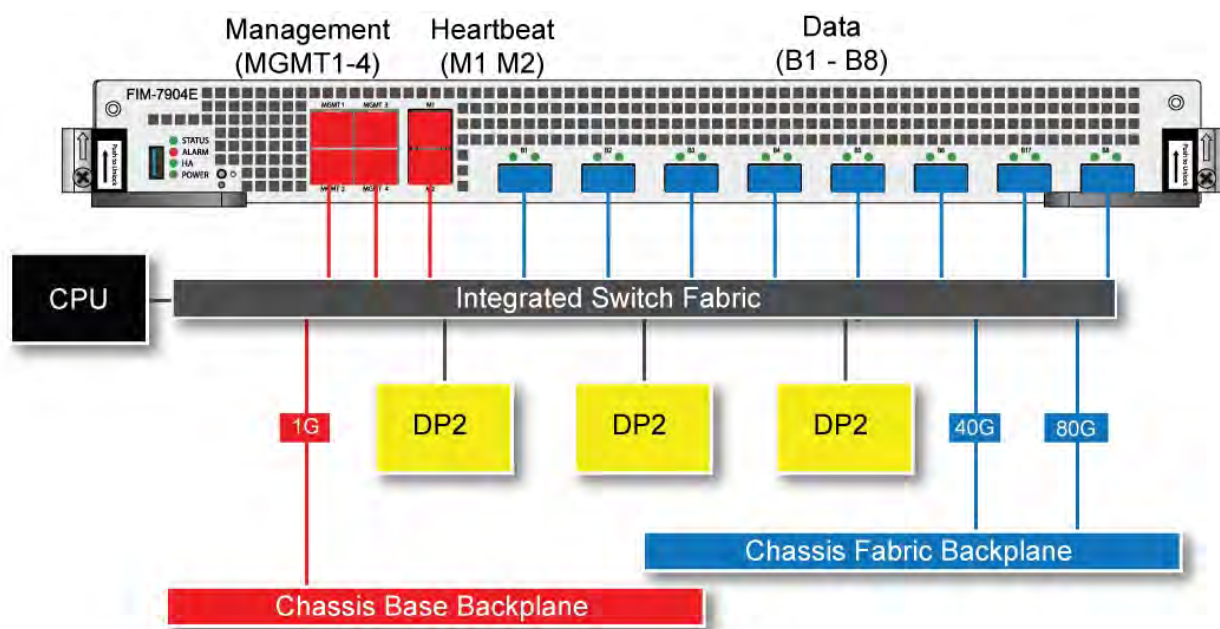

In a FortiGate-7000 chassis, FPM-7620E NP6 network processors combined with the FortiGate Interface Module (FIM) Integrated Switch Fabric (ISF) provide hardware acceleration by offloading sessions from the FPM-7620E CPUs. The result is enhanced network performance provided by the NP6 processors plus the removal of network processing load from the FPM-7620 CPUs. The NP6 processors can also handle some CPU-intensive tasks, like IPsec VPN encryption/decryption. Because of the ISF in each FIM, all sessions are fast-pathed and accelerated.

FPM-7620E hardware architecture**FIM-7901E fast path architecture**

The FIM-7901E includes an integrated switch fabric (ISF) that connects the FIM front panel interfaces to the DP2 session-aware load balancers and to the chassis fabric and base backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7901E schematic**FIM-7904E fast path architecture**

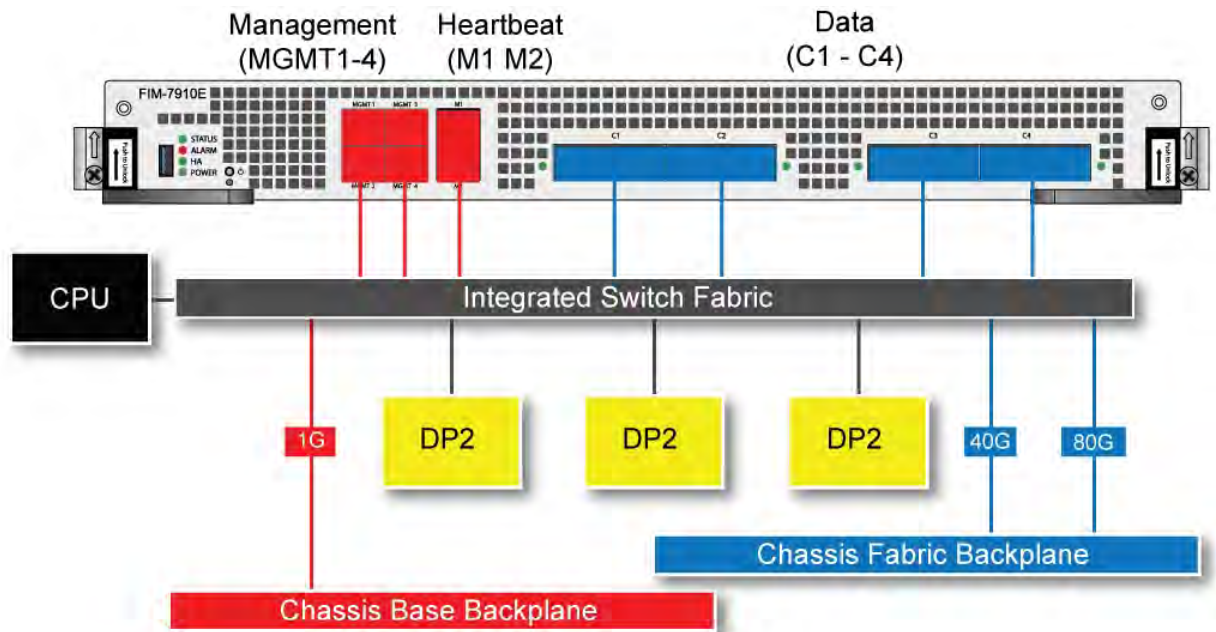

The FIM-7904E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7904E hardware architecture

FIM-7910E fast path architecture

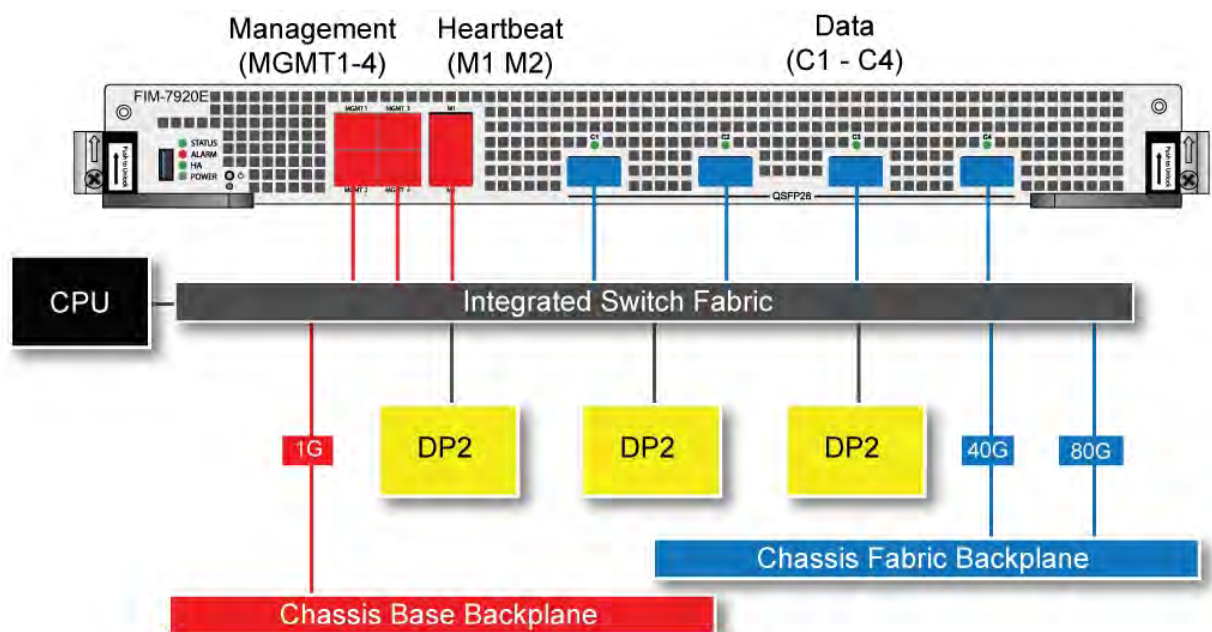

The FIM-7910E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7910E hardware schematic

FIM-7920E fast path architecture

The FIM-7920E includes an integrated switch fabric (ISF) that connects the front panel interfaces to the DP2 session-aware load balancers and to the chassis backplanes. The ISF also allows the DP2 processors to distribute sessions among all NP6 processors on the FortiGate Processor Modules (FPM) in the FortiGate-7000 chassis.

FIM-7920E hardware schematic**FortiGate NP6lite architectures**

This chapter shows the NP6lite architecture for the all FortiGate models that include NP6lite processors.

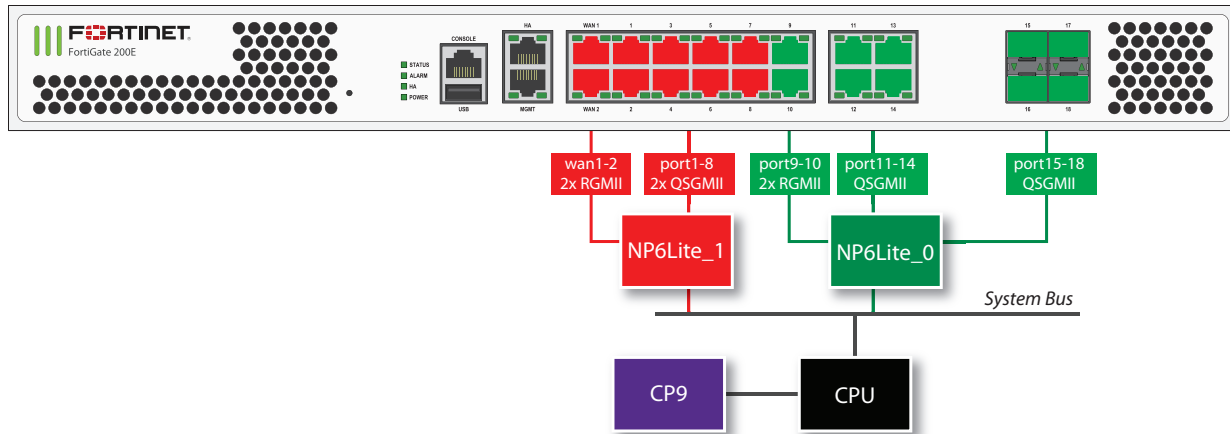

FortiGate-200E and 201E fast path architecture

The FortiGate-200E and 201E include two NP6lite processors. Because of this model does not include a switch fabric, you cannot create Link Aggregation Groups (LAGs) or redundant interfaces between interfaces connected to different NP6lites. As well traffic will only be offloaded if it enters and exits the FortiGate on interfaces connected to the same NP6lite.

The NP6lites are connected to network interfaces as follows:

- NP6lite_0 is connected to six 1GE RJ-45 interfaces (port9-port14) and four 1GE SFP interfaces (port15-18).
- NP6lite_1 is connected to ten 1GE RJ45 interfaces (wan1, wan2, port1-port8).

The following diagram also shows the RGMII and QSGMII port connections between the NP6lite processors and the front panel interfaces. Both RGMII and QSGMII interfaces operate at 1000Mbps. However, QSGMII interfaces can also negotiate to operate at lower speeds: 10, 100, and 1000Mbps. To connect the FortiGate-200E to networks with speeds lower than 1000Mbps use the QSGMII interfaces (port1-8 and port11-18).

You can use the following `get` command to display the FortiGate-200E or 201E NP6lite configuration. You can also use the `diagnose npu np6lite port-list` command to display this information.

```

```

NP4 and NP4Lite Acceleration

NP4 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP4 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP4 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP4 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP4 processor plus the network processing load is removed from the CPU. In addition, the NP4 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

NP4lite processors have the same architecture and function in the same way as NP4 processors. All of the descriptions of NP4 processors in this document can be applied to NP4lite processors except where noted.

Session keys (and IPsec SA keys) are stored in the memory of the NP4 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP4. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP4s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP4s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements because traffic enters and exits on interfaces connected to the same ISF. Most FortiGate models with multiple NP4 processors connect all interfaces and NP4 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There is one limitation to keep in mind; the capacity of each NP4 processor. An individual NP4 processor has a capacity of 20 Gbps (10 Gbps ingress and 10 Gbps egress). Once an NP4 processor hits its limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP4 processors. To be able to do this you need to be aware of which interfaces connect to which NP4 processors and distribute incoming traffic accordingly.

Some FortiGate units contain one NP4 processor with all interfaces connected to it and to the ISF. As a result, offloading is supported for traffic between any pair of interfaces.

Some FortiGate units include NP4Lite processors. These network processors have the same functionality and limitations as NP4 processors but with about half the performance. Also, NP4Lite processors do not support traffic shaping for offloaded sessions. NP4lite processors can be found in mid-range FortiGate models such as the FortiGate-200D and 240D.

Viewing your FortiGate's NP4 configuration

To list the NP4 network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu np4 list
```

The output lists the interfaces that have NP4 processors. For example, for a FortiGate-5001C:

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board   port1 port2 port3 port4
```

```

1      On-board      fabric1 base1 npu0-vlink0 npu0-vlink1
                    port5 port6 port7 port8
                    fabric2 base2 npu1-vlink0 npu1-vlink1

```

NP4lite CLI commands (disabling NP4Lite offloading)

If your FortiGate unit includes an NP4Lite processor the following commands will be available:

- Use the following command to disable or enable NP4Lite offloading. By default NP4lite offloading is enabled. If you want to disable NP4Lite offloading to diagnose a problem enter:

```
diagnose npu nplite fastpath disable
```

This command disables NP4Lite offloading until your FortiGate reboots. You can also re-enable offloading by entering the following command:

```
diagnose npu nplite fastpath enable
```

- NP4lite debug command. Use the following command to debug NP4Lite operation:

```
diagnose npl npl_debug {<parameters>}
```

NP4Lite option to disable offloading ICMP traffic in IPsec tunnels

In some cases ICMP traffic in IPsec VPN tunnels may be dropped by the NP4Lite processor due to a bug with the NP4Lite firmware. You can use the following command to avoid this problem by preventing the NP4Lite processor from offloading ICMP sessions in IPsec VPN tunnels. This command is only available on FortiGate models with NP4Lite processors, such as the FortiGate/FortiWiFi-60D.

```

config system npu
    set process-icmp-by-host {disable | enable}
end

```

The option is disabled by default and all ICMP traffic in IPsec VPN tunnels is offloaded where possible. If you are noticing that ICMP packets in IPsec VPN tunnels are being dropped you can disable this option and have all ICMP traffic processed by the CPU and not offloaded to the NP4Lite.

NP4 and NP4Lite processors and sFlow and NetFlow

Configuring sFlow or NetFlow on any interface disables all NP4 or NP4Lite offloading for all traffic on that interface.

Configuring NP4 traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

NP4 session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)

- Firewall policies must not include proxy-based security features (proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, Anti-Spam, VoIP, ICAP, Web Application Firewall, or Proxy options).
- If the FortiGate supports NTurbo, firewall policies can include flow-based security features (IPS, Application Control CASI, flow-based antivirus, or flow-based web filtering) .
- Origin must not be local host (the FortiGate unit)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable NP4 hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [Offloading NP4 anomaly detection on page 1693](#)

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP4.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

Increasing NP4 offloading capacity using link aggregation groups (LAGs)

NP4 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 3 Gbps link by adding three 1Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP4 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP4 processor, traffic received by that LAG is offloaded by that NP4 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP4 processor.

If a FortiGate has two or more NP4 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP4 processors. You do this by adding physical interfaces connected to different NP4 processors to the same LAG.

Adding a second NP4 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP4 or tripled by adding a third. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP4s is supported by the ISF that allows multiple NP4 processors to share session information. On models that have more than one NP4 and no ISF, if you attempt to add interfaces connected to different NP4 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP4 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPsec is configured on a LAG that has interfaces connected to multiple NP4 processors.
- Using a LAG connected to multiple NP4 processors for decrypting incoming IPsec VPN traffic may cause some of the incoming traffic to be decrypted by the CPU. So this configuration is not recommended since not all decryption is offloaded. (Using a LAG connected to multiple NP4 processors for encrypting outgoing IPsec VPN traffic is supported with no limitations.)
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP4 LAG group to 1Gbps.

NP4 traffic shaping offloading

Accelerated Traffic shaping is supported by NP4 processors with the following limitations.

- NP4 processors support policy-based traffic shaping. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported.
- DSCP configurations are supported.
- Per-IP traffic shaping is supported.
- QoS in general is not supported.

NP4Lite processors do not support traffic shaping for offloaded sessions.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling NP4 offloading. See [Disabling NP offloading for firewall policies on page 1598](#).

NP4 IPsec VPN offloading

NP4 processors improve IPsec tunnel performance by offloading IPsec encryption and decryption.

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- Origin can be local host (the FortiGate unit)
- In Phase 1 configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor
- in Phase 2 configuration:
 - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
 - authentication must be MD5, SHA1, or null
 - if encryption is null, authentication must not also be null

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase 1 negotiations to establish the security association (SA). The SA includes cryptographic processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
 - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
 - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources
- IPsec encryption offload
 - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
 - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

Configuring Inter-VDOM link acceleration with NP4 processors

FortiGate units with NP4 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an NP4 processor. If you disable NP4 offloading traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for those policies. You can also use the following command to disable all IPS offloading

```
config ips global
    set np-accel-mode none
    set cp-accel-mode none
end
```

- For a FortiGate unit with two NP4 processors there are also two inter-VDOM links, each with two interfaces:
 - **npu0-vlink:**
npu0-vlink0
npu0-vlink1
 - **npu1-vlink:**
npu1-vlink0
npu1-vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP4 interfaces, enter the following CLI command (output shown for a FortiGate-5001B):

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board      port1 port2 port3 port4
        fabric1 base1 npu0-vlink0 npu0-vlink1
1       On-board      port5 port6 port7 port8
        fabric2 base2 npu1-vlink0 npu1-vlink1
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in a pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**.

This results in an inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
    edit npu0-vlink1
        set vdom New-VDOM
    end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0-vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0-vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```

config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0-vlink0
    set vlanid 100
  next
  edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0-vlink1
    set vlanid 100

```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP4 processor.

diagnose ip address list

```

IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55 devname=IVL-VLAN1_ROOT
IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56 devname=IVL-VLAN1_VDOM1

```

diagnose sys session list

```

session info: proto=1 proto_state=00 duration=282 expire=24 timeout=0 session info:

```

Offloading NP4 anomaly detection

Network interfaces associated with a port attached to an NP4 processor can be configured to offload anomaly checking to the NP4 processor. This anomaly checking happens before other offloading and separately from DoS policy anomaly checking. Using the following command, each FortiGate interface can have a different anomaly checking configuration even if they are connected to the same NP4 processor.

The options available for this command apply anomaly checking for NP4 sessions in the same way as the command described in [Configuring individual NP6 processors on page 1614](#) applies anomaly checking for for NP6 sessions.

```
config system interface
  edit <port-name>
    set fp-anomaly <anomalies>
  end
```

where <anomalies> can be one, more than one or all of the following:

Anomaly	Description
drop_icmp_frag	Drop ICMP fragments to pass.
drop_icmpland	Drop ICMP Land.
drop_ipland	Drop IP Land.
drop_iplsrr	Drop IP with Loose Source Record Route option.
drop_iprr	Drop IP with Record Route option.
drop_ipsecurity	Drop IP with Security option.
drop_ipssrr	Drop IP with Strict Source Record Route option.
drop_ipstream	Drop IP with Stream option.
drop_iptimestamp	Drop IP with Timestamp option.
drop_ipunknown_option	Drop IP with malformed option.

Anomaly	Description
drop_ipunknown_prot	Drop IP with Unknown protocol.
drop_tcp_fin_noack	Drop TCP FIN with no ACT flag set to pass.
drop_tcp_no_flag	Drop TCP with no flag set to pass.
drop_tcpland	Drop TCP Land.
drop_udpland	Drop UDP Land.
drop_winnuke	Drop TCP WinNuke.
pass_icmp_frag	Allow ICMP fragments to pass.
pass_icmpland	Allow ICMP Land to pass.
pass_ipland	Allow IP land to pass.
pass_iplsrr	Allow IP with Loose Source Record Route option to pass.
pass_iprr	Allow IP with Record Route option to pass.
pass_ipsecurity	Allow IP with Security option to pass.
pass_ipssrr	Allow IP with Strict Source Record Route option to pass.
pass_ipstream	Allow IP with Stream option to pass.
pass_iptimestamp	Allow IP with Timestamp option to pass.
pass_ipunknown_option	Allow IP with malformed option to pass.
pass_ipunknown_prot	Allow IP with Unknown protocol to pass.
pass_tcp_fin_noack	Allow TCP FIN with no ACT flag set to pass.
pass_tcp_no_flag	Allow TCP with no flag set to pass.
pass_tcpland	Allow TCP Land to pass.
pass_udpland	Allow UDP Land to pass.
pass_winnuke	Allow TCP WinNuke to pass.

Example

You might configure an NP4 to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

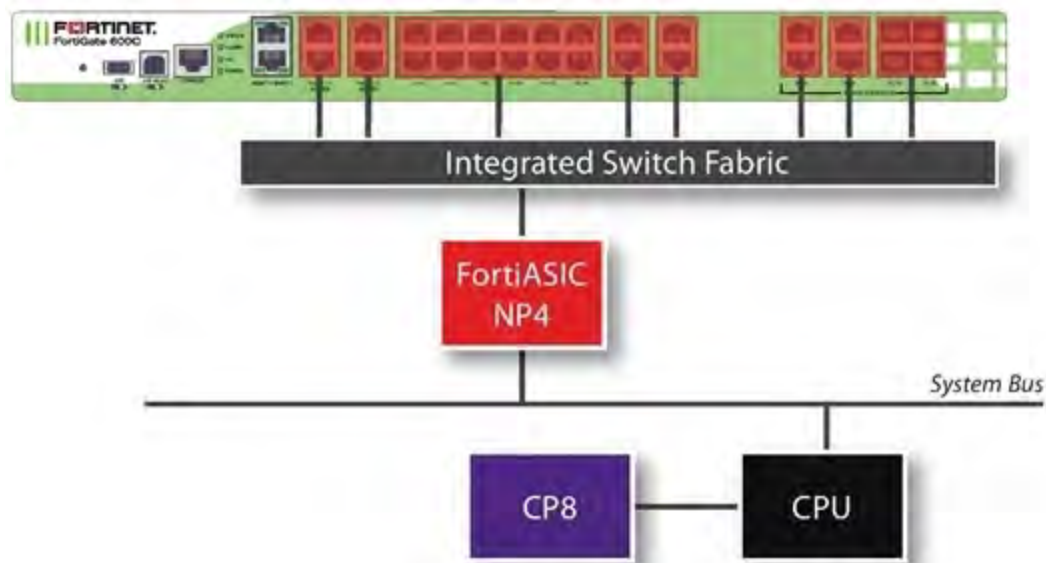

```
config system interface
  edit port1
    set fp-anomaly drop_winnuke drop_ipunknown_prot pass_iptimestamp
  end
```

FortiGate NP4 architectures

This chapter shows the NP4 architecture for the all FortiGate models that include NP4 processors.

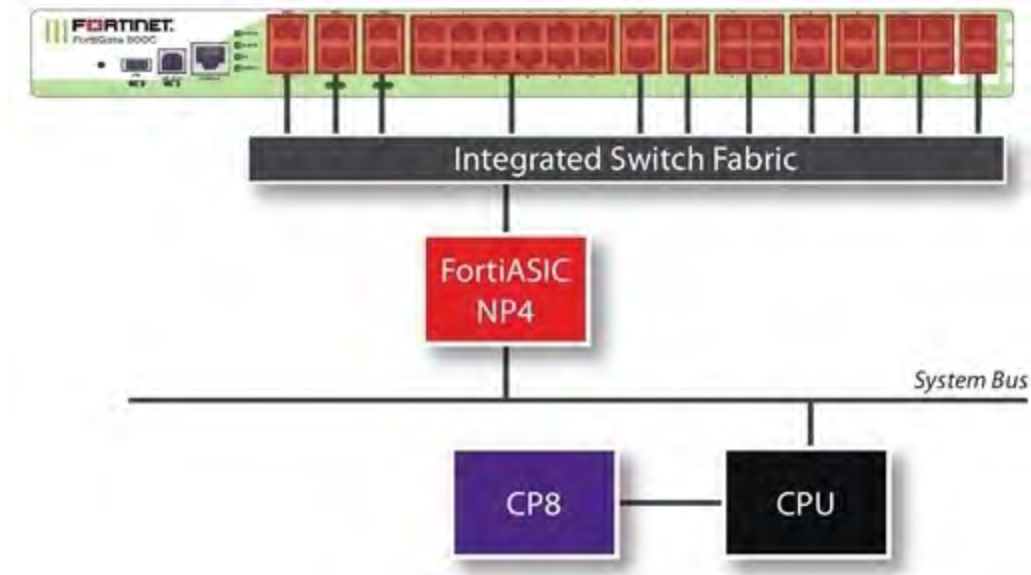

FortiGate-600C

The FortiGate-600C features one NP4 processor. All the ports are connected to this NP4 over the Integrated Switch Fabric. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are four 1Gb SFP interface ports duplicating the port19-port22 connections.

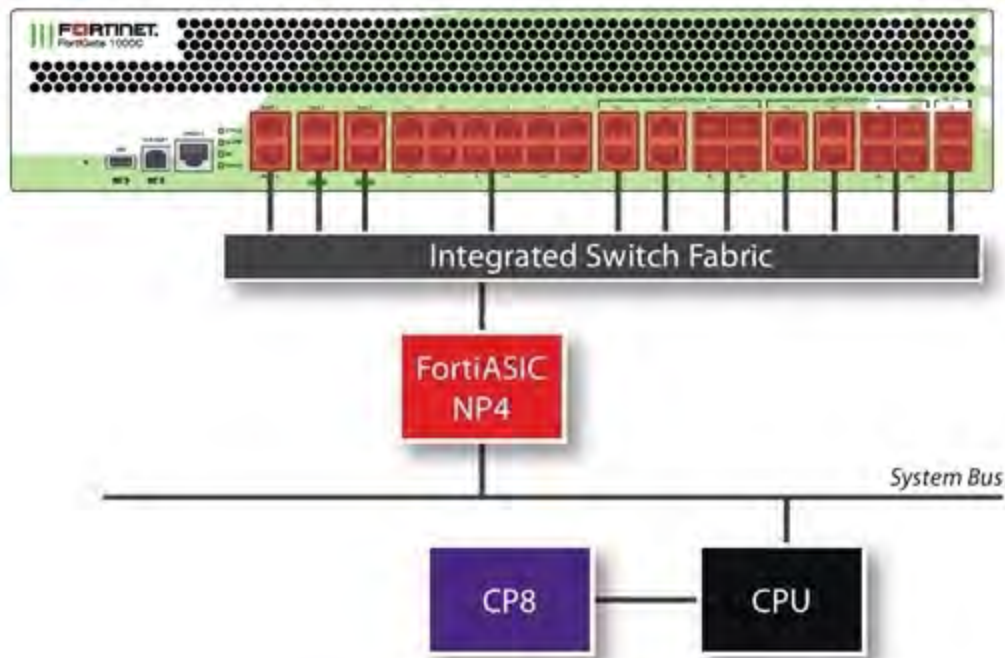

FortiGate-800C

The FortiGate-800C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 Ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

FortiGate-1000C

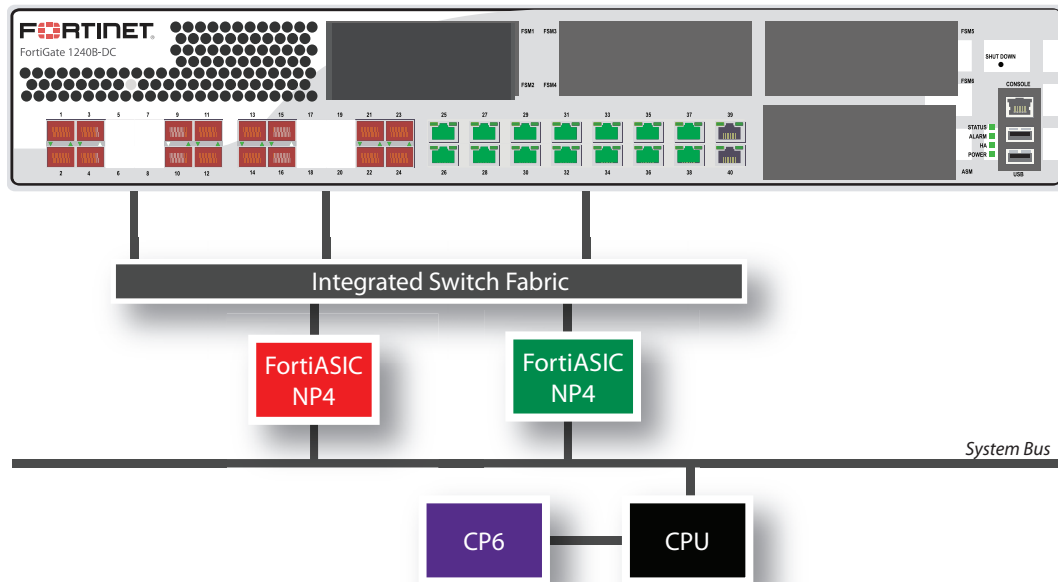

The FortiGate-1000C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

FortiGate-1240B

The FortiGate-1240B features two NP4 processors:

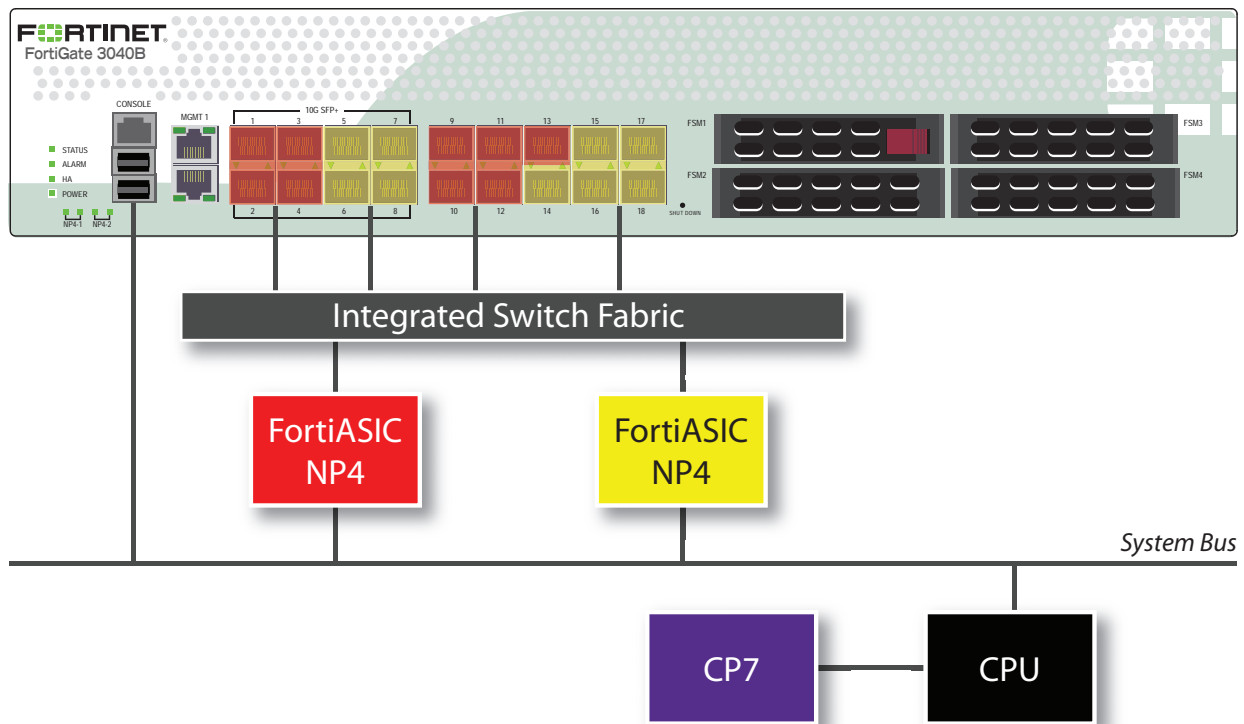

- Port1 to port24 are 1Gb SFP interfaces connected to one NP4 processor.
- Port25 to port38 are RJ-45 ethernet ports, connected to the other NP4 processor.
- Port39 and port40 are not connected to an NP4 processor.

FortiGate-3040B

The FortiGate-3040B features two NP4 processors:

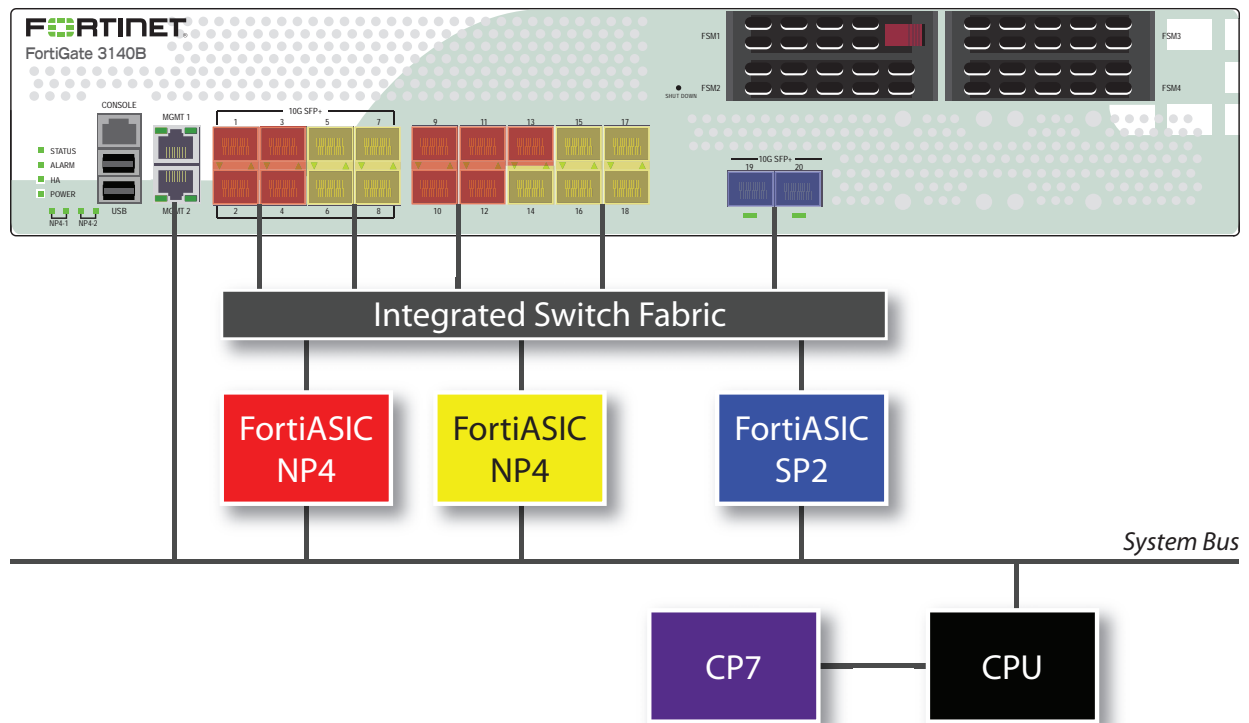

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.

FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor:

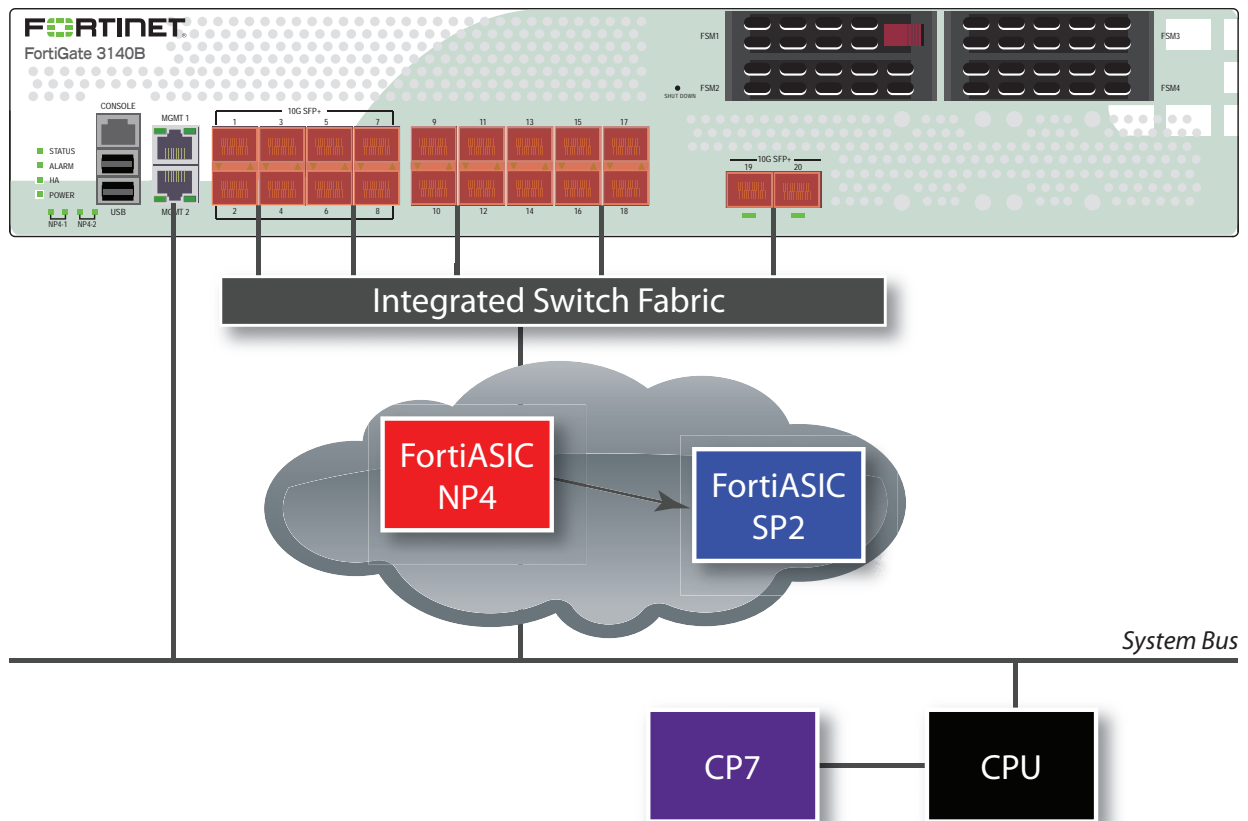

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10Gb interfaces, port19 and port20, share connections to the SP2 processor.

FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

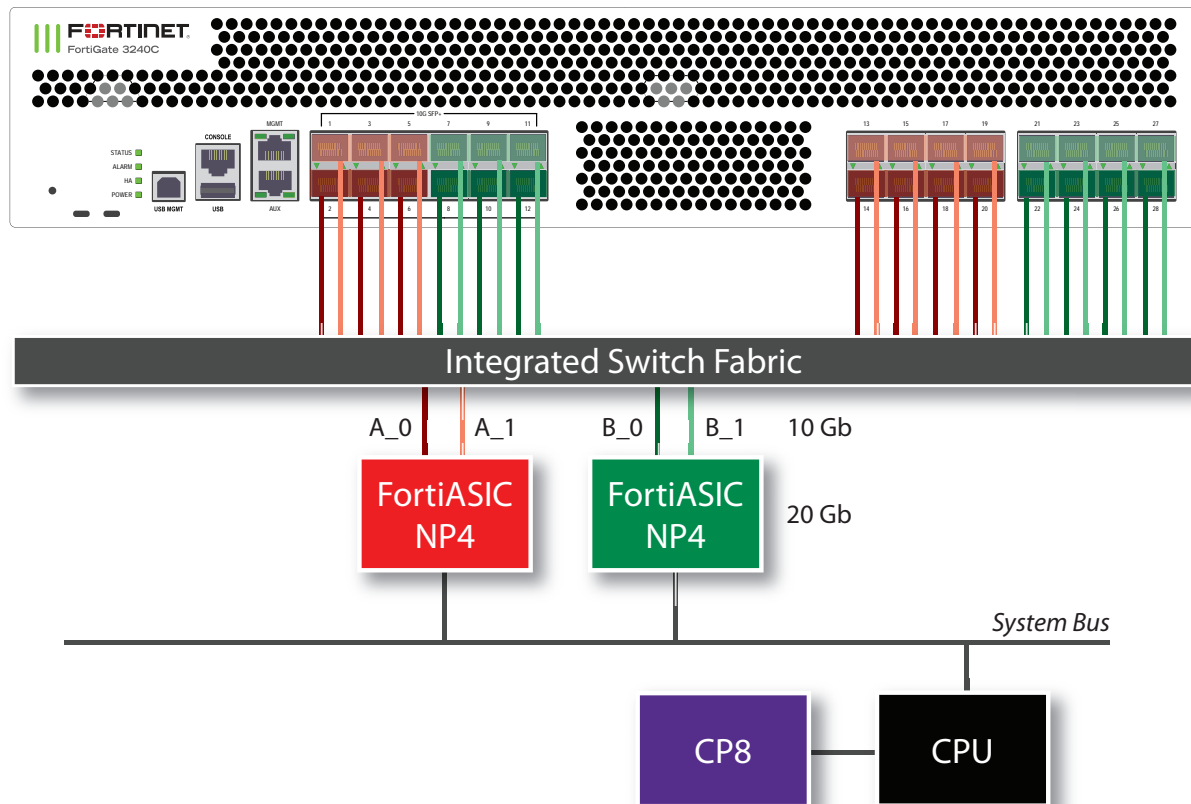

```
config system global
    set sp-load-balance disable
end
```

FortiGate-3240C

The FortiGate-3240C features two NP4 processors:

- The 10Gb interfaces, port1 through port6, and the 1Gb interfaces, port13 through port20, share connections to one NP4 processor.
- The 10Gb interfaces, port7 through port12, and the 1Gb interfaces, port21 through port28, share connections to the other NP4 processor.

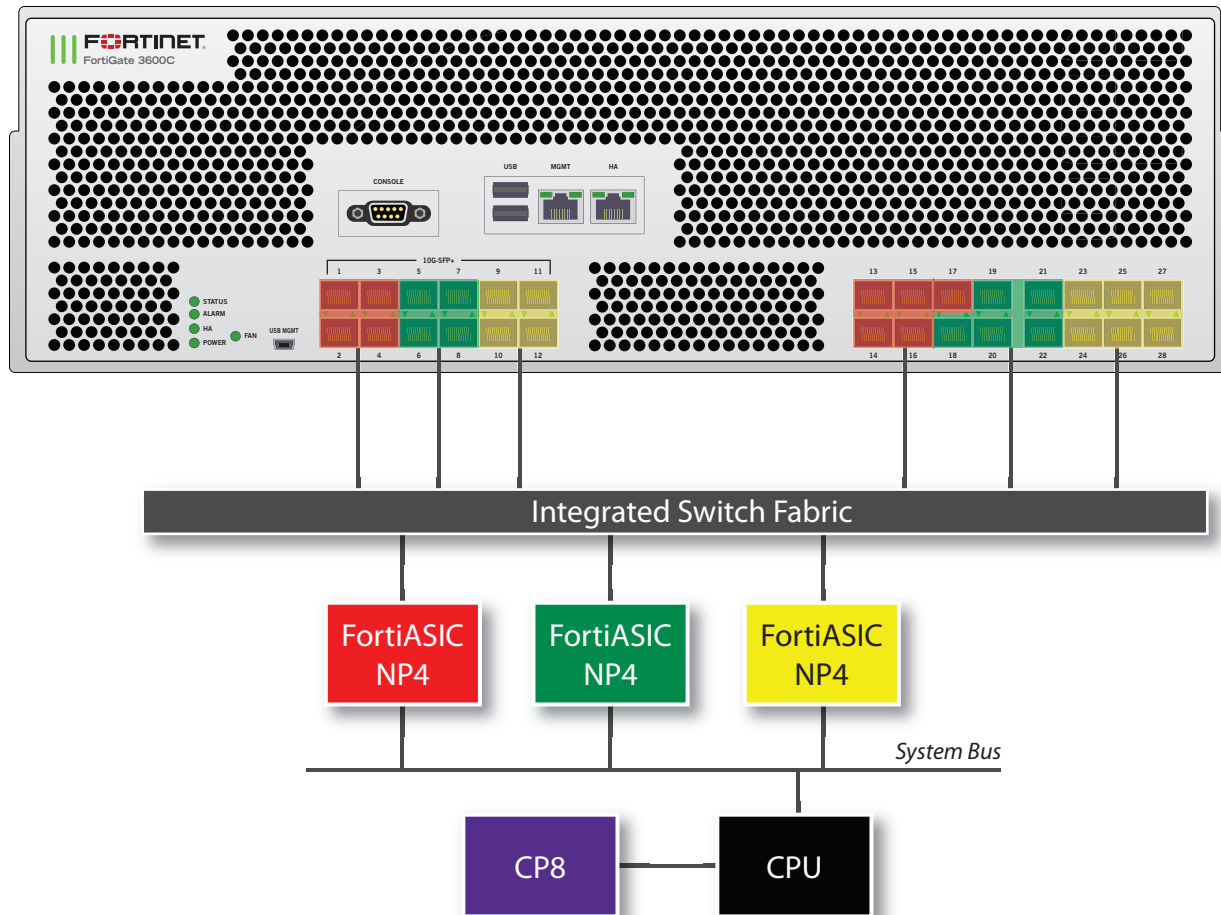

In addition to the ports being divided between the two NP4 processors, they are further divided between the two connections to each processor. Each NP4 can process 20 Gb of network traffic per second and each of two connections to each NP4 can move 10Gb of data to the processor per second, so the ideal configuration would have no more than 10 Gb of network traffic to each connection of each NP4 at any time.

FortiGate-3600C

The FortiGate-3600C features three NP4 processors:

- The 10Gb interfaces, port1-port4, and the 1Gb interfaces, port13-port17, share connections to one NP4 processor.
- The 10Gb interfaces, port5-port8, and the 1Gb interfaces, port18-port22 share connections to the second NP4 processor.
- The 10Gb interfaces, port9-port12, and the 1Gb interfaces, port23-port28 share connections to the third NP4 processor.

FortiGate-3600C XAUI links

The FortiGate-3600C uses XAUI links for communication between physical Ethernet ports and the integrated switch fabric.

Each XAUI link has a maximum bandwidth of 10-Gigabits. The reason you may need to know about the XAUI link in NP4 configurations is because of this 10-Gigabit limit. Because of this limitation, the total amount of data processed by all Ethernet interfaces connected to an XAUI link cannot exceed 10 gigabits. In some cases this may limit the amount of bandwidth that the FortiGate can process.

Each NP4 processor connects to the integrated switch fabric through two XAUI links: XAUI0 and XAUI1. All of the odd numbered Ethernet interfaces use XAUI0 and all of the even numbered interfaces use XAUI1:

NPU1

XAUI0 = port1, port3, port13, port15, port17

XAUI1 = port2, port4, port14, port16

NPU2

XAUI0 = port5, port7, port18, port20, port22

XAUI1 = port6, port8, port19, port21

NPU3

XAUI0 = port9, port11, port23, port25, port27

XAUI1 = port10, port12, port24, port26, port28

Usually you do not have to be concerned about XAUI link mapping. However, if a FortiGate-3600C NP4 interface is processing a very high amount of traffic you should distribute that traffic among both of the XAUI links connected to it. So if you have a very high volume of traffic flowing between two networks you should connect both networks to the same NP4 processor but to different XAUI links. For example, you could connect one network to Ethernet port5 and the other network to Ethernet port6. In this configuration, the second NP4 processor would handle traffic acceleration and both XAUI links would be processing traffic.

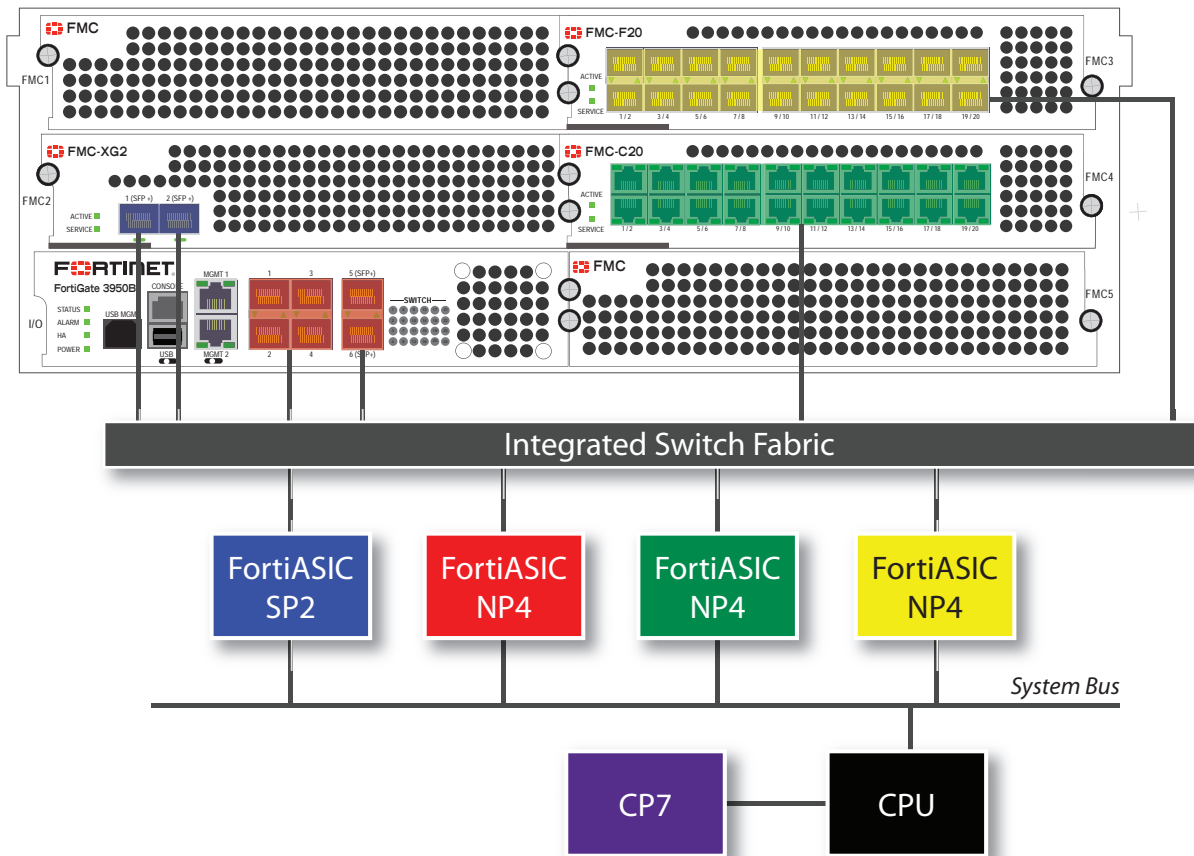

FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor. The 1Gb SPF interfaces, port1, port2, port3, port4, and the 10Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. The diagram below shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one SP2 processor. The 10Gb SPF+ interfaces, port1 and port2, share connections to the processor.
- The FMC-F20 has one NP4 processor and the twenty 1Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.

- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.

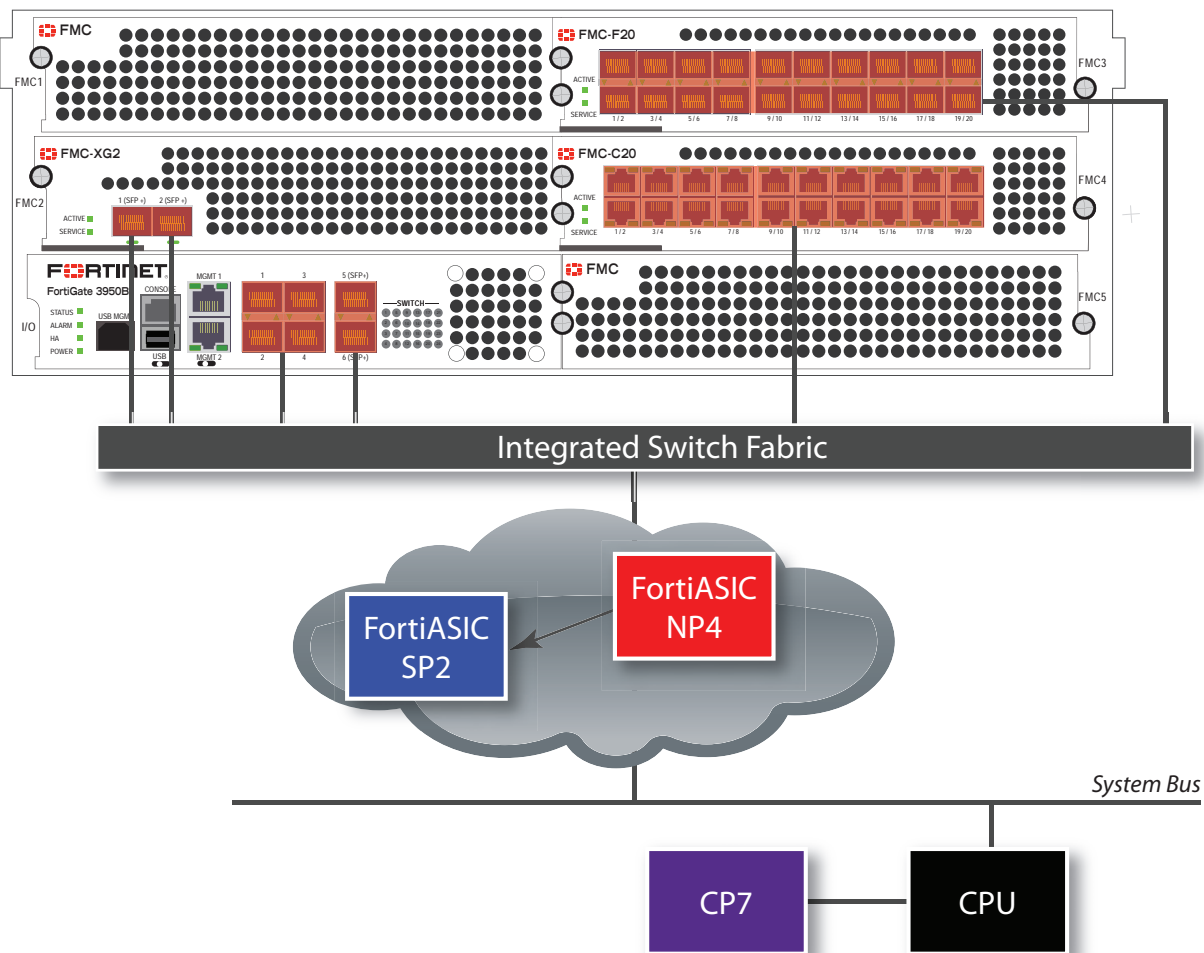

FortiGate-3950B and FortiGate-3951B — load balance mode

Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

The FortiGate-3950B in load balance mode

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

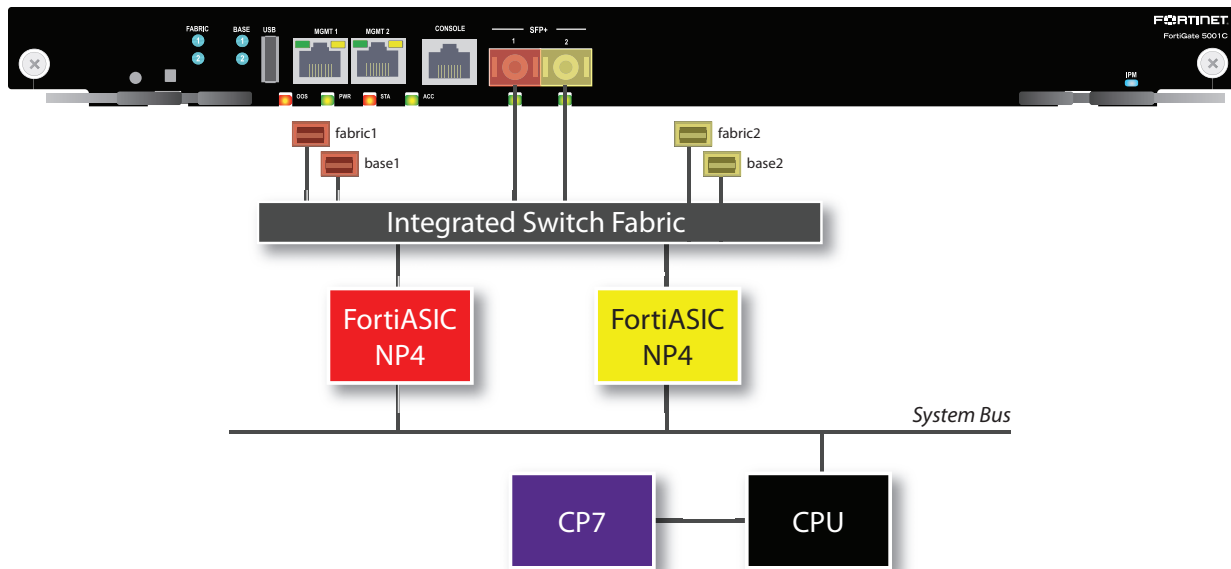

To return to the default mode, issue this CLI command.

```
config system global
    set sp-load-balance disable
end
```

FortiGate-5001C

The FortiGate-5001C board includes two NP4 processors connected to an integrated switch fabric:

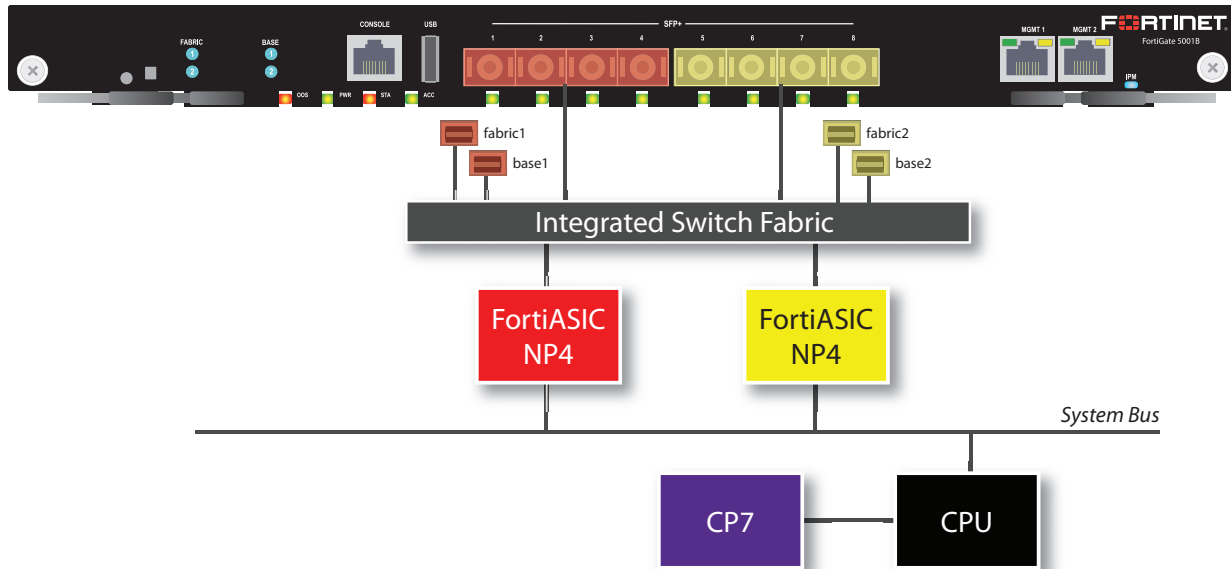

- The port1, fabric1, and base1 interfaces are connected to one NP4 processor.
- The port2, fabric2, and base2 interfaces are connected to the other NP4 processor.

FortiGate-5001B

The FortiGate-5001B board includes two NP4 connected to an integrated switch fabric.

- The port1, port2, port3, port4, fabric1 and base1 interfaces are connected to one NP4 processor.
- The port5, port6, port7, port8, fabric2 and base2 interfaces are connected to the other NP4 processor.

Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10Gb/s ports, but the NP4 processor it contains has only two 10Gb/s ports. The external ports you use are important to optimize the SP for your application.

ADM-XD4 mapping mode

Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

Hardware acceleration get and diagnose commands

This section describes some `get` and `diagnose` commands you can use to display useful information about the NP6 processors sessions processed by NP6 processors.

get hardware npu np6

You can use the `get hardware npu np6` command to display information about the NP6 processors in your FortiGate and the sessions they are processing. This command contains a subset of the options available from the `diagnose npu np6` command. The command syntax is:

```
get hardware npu np6 {dce <np6-id> | ipsec-stats | port-list | session-stats <np6-id> |
  sse-stats <np6-id> | synproxy-stats}
```

`<np6-id>` identifies the NP6 processor. 0 is `np6_0`, 1 is `np6_1` and so on.

`dce` show NP6 non-zero sub-engine drop counters for the selected NP6.

`ipsec-stats` show overall NP6 IPsec offloading statistics.

`port-list` show the mapping between the FortiGate's physical ports and its NP6 processors.

`session-stats` show NP6 session offloading statistics counters for the selected NP6.

`sse-stats` show hardware session statistics counters.

`synproxy-stats` show overall NP6 synproxy statistics for TCP connections identified as being syn proxy DoS attacks.

diagnose npu np6

The `diagnose npu np6` command displays extensive information about NP6 processors and the sessions that they are processing. Some of the information displayed can be useful for understanding the NP6 configuration, seeing how sessions are being processed and diagnosing problems. Some of the commands may only be useful for Fortinet software developers. The command syntax is:

```
diagnose npu np6 {options}
```

The following options are available:

`fastpath {disable | enable} <np6-od>` enable or disable fastpath processing for a selected NP6.

`dce` shows NP6 non-zero sub-engine drop counters for the selected NP6.

`dce-all` show all subengine drop counters.

`anomaly-drop` show non-zero L3/L4 anomaly check drop counters.

`anomaly-drop-all` show all L3/L4 anomaly check drop counters.

`hrx-drop` show non-zero host interface drop counters.

`hrx-drop-all` show all host interface drop counters.

`session-stats` show session offloading statistics counters.

`session-stats-clear` clear session offloading statistics counters.

`sse-stats` show hardware session statistics counters.

`sse-stats-clear` show hardware session statistics counters.

`pdq` show packet buffer queue counters.

`xgmac-stats` show XGMAC MIBs counters.

`xgmac-stats-clear` clear XGMAC MIBS counters.

`port-list` show port list.

`ipsec-stats` show IPsec offloading statistics.

`ipsec-stats-clear` clear IPsec offloading statistics.

`eeeprom-read` read NP6 EEPROM.

`npu-feature` show NPU feature and status.

`register` show NP6 registers.

`fortilink` configure fortilink.

`synproxy-stats` show synproxy statistics.

Using diagnose npu np6 npu-feature to verify enabled NP6 features

You can use the `diagnose npu np6 npu-feature` command to see what NP6 features are enabled and which are not. The following command output shows the normal default NP6 configuration for most FortiGates. In this output all features are enabled except low latency features and GRE offloading. Low latency is only available on the FortiGate-3700D and DX models and GRE offloading will become available in a future FortiOS release. The following output is from a FortiGate-1500D

```
diagnose npu np6 npu-feature
-----
```

	np_0	np_1
Fastpath	Enabled	Enabled
Low-latency-mode	Disabled	Disabled
Low-latency-cap	No	No
IPv4 firewall	Yes	Yes
IPv6 firewall	Yes	Yes
IPv4 IPSec	Yes	Yes
IPv6 IPSec	Yes	Yes
IPv4 tunnel	Yes	Yes
IPv6 tunnel	Yes	Yes
GRE tunnel	No	No
IPv4 Multicast	Yes	Yes
IPv6 Multicast	Yes	Yes
CAPWAP	Yes	Yes

If you use the following command to disable fastpath for np_0:

```
config system np6
  edit np6_0
    set fastpath disable
  end
```

The `npu-feature` command output show this configuration change:

```
diagnose npu np6 npu-feature
-----
```

	np_0	np_1
Fastpath	Disabled	Enabled
Low-latency-mode	Disabled	Disabled
Low-latency-cap	No	No
IPv4 firewall	Yes	Yes
IPv6 firewall	Yes	Yes
IPv4 IPSec	Yes	Yes
IPv6 IPSec	Yes	Yes
IPv4 tunnel	Yes	Yes
IPv6 tunnel	Yes	Yes
GRE tunnel	No	No
IPv4 Multicast	Yes	Yes
IPv6 Multicast	Yes	Yes
CAPWAP	Yes	Yes

Using the diagnose sys session/session6 list command

The `diagnose sys session list` and `diagnose sys session6 list` commands list all of the current IPv4 or IPv6 sessions being processed by the FortiGate. For each session the command output includes an `npu info` line that displays NPx offloading information for the session. If a session is not offloaded the command output includes a `no_ofld_reason` line that indicates why the session was not offloaded.

Displaying NP6 offloading information for a session

The `npu info` line of the `diagnose sys session list` command includes information about the offloaded session that indicates the type of processor and whether its IPsec or regular traffic:

- `offload=1/1` for NP1(FA1) sessions.
- `offload=2/2` for NP1(FA2) sessions.
- `offload=3/3` for NP2 sessions.
- `offload=4/4` for NP4 sessions.
- `offload=5/5` for XLR sessions.
- `offload=6/6` for Nplite/NP4lite sessions.
- `offload=7/7` for XLP sessions.
- `offload=8/8` for NP6 sessions.
- `flag 0x81` means regular traffic.
- `flag 0x82` means IPsec traffic.

Example offloaded IPv4 NP6 session

The following session output by the `diagnose sys session list` command shows an offloaded session. The information in the `npu info` line shows this is a regular session (`flag=0x81/0x81`) that is offloaded by an NP6 processor (`offload=8/8`).

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=4599 expire=2753 timeout=3600 flags-

diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions)

You can use the `diagnose npu np6 portlist` command to list the NP6-ids and the interfaces that each NP6 is connected to. The <np6-id> of np6_0 is 0, the <np6-id> of np6_1 is 1 and so on. The `diagnose npu np6 session-stats <np6-id>` command output includes the following headings:

- `ins44` installed IPv4 sessions
- `ins46` installed NAT46 sessions
- `del4` deleted IPv4 and NAT46 sessions
- `ins64` installed NAT64 sessions
- `ins66` installed IPv6 sessions
- `del6` deleted IPv6 and NAT64 sessions
- `e` is the error counter for each session type

```
diagnose npu np6 session-stats 0
```

diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions)

This command lists all IPv4 or IPv6 multicast sessions. If a multicast session can be offloaded, the output includes the `offloadable` tag. If the multicast path can be offloaded one of the paths in the command output is tagged as `offloaded`.

The only way to determine the number of offloaded multicast sessions is to use the `diagnose sys mcast-session/session6 list` command and count the number of sessions with the `offload` tag.

```
diagnose sys mcast-session list
session info: id=3 vf=0 proto=17 172.16.200.55.51108->239.1.1.1.7878
used=2 path=11 duration=1 expire=178 indev=6 pkts=2 state:2cpu offloadable
npn-info in-pid=0 vifid=0 in-vtag=0 npuid=0 queue=0 tae=0

path: 2cpu policy=1, outdev=2
      out-vtag=0
path: 2cpu policy=1, outdev=3
      out-vtag=0

      out-vtag=0
path: policy=1, outdev=11
      out-vtag=0
path: policy=1, outdev=12
      out-vtag=0
path: policy=1, outdev=13
      out-vtag=0
path: 2cpu policy=1, outdev=64
      out-vtag=0
path: 2cpu policy=1, outdev=68
      out-vtag=0
```

diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions)

This command displays the total number of inserted, deleted and purged sessions processed by a selected NP6 processor. The number of dropped sessions of each type can be determined by subtracting the number of successful sessions from the total number of sessions. For example, the total number of dropped insert sessions is `insert-total - insert-success`.

```
diagnose npu np6 sse-stats 0
```

Counters	SSE0	SSE1	Total

active	0	0	0
insert-total	25	0	0
insert-success	25	0	0
delete-total	25	0	0
delete-success	25	0	0
purge-total	0	0	0
purge-success	0	0	0
search-total	40956	38049	79005
search-hit	37714	29867	67581

pht-size	8421376	8421376	
oft-size	8355840	8355840	
oftfree	8355839	8355839	
PBA	3001		

diagnose npu np6 dce <np6-id> (number of dropped NP6 packets)

This command displays the number of dropped packets for the selected NP6 processor.

- `IHP1_PKTCHK` number of dropped IP packets
- `IPSEC0_ENGINB0` number of dropped IPSec
- `TPE_SHAPER` number of dropped traffic sharper packets

```
diag npu np6 dce 1
IHP1_PKTCHK :00000000000001833 [5b] IPSEC0_ENGINB0 :0000000000000003 [80]
TPE_SHAPER :00000000000000552 [94]
```

diagnose hardware deviceinfo nic <interfac-name> (number of packets dropped by an interface)

This command displays a wide variety of statistics for FortiGate interfaces. The fields `Host Rx dropped` and `Host Tx dropped` display the number of received and transmitted packets that have been dropped.

```
diagnose hardware deviceinfo nic port2
```

```
...
```

```
===== Counters =====
```

```
Rx Pkts          :20482043

diagnose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs)

This command displays information about NP6 syn-proxy sessions including the total number proxied sessions. As well the Number of attacks, no ACK from client shows the total number of unacknowledged SYNs.

```
diagnose npu np6 synproxy-stats
DoS SYN-Proxy:
Number of proxied TCP connections : 39277346
Number of working proxied TCP connections : 182860
Number of retired TCP connections : 39094486
Number of attacks, no ACK from client : 208
```

Chapter 15 - High Availability

High availability

This document describes FortiGate HA, the FortiGate Clustering Protocol (FGCP), The FortiGate Session Life Support Protocol (FGSP) and FortiGate VRRP.

This FortiOS Handbook chapter contains the following sections:

[Solving the high availability problem](#) describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

[An introduction to the FGCP](#) introduces the FGCP clustering protocol and many of its features and terminology.

[FGCP configuration examples and troubleshooting](#) describes configuring HA clusters and contains HA clustering configuration examples.

[Virtual clusters](#) describes configuring HA virtual clusters and contains virtual clustering configuration examples.

[Full mesh HA](#) describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

[Operating clusters and virtual clusters](#) describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

[HA and failover protection](#) describes in detail how FortiGate HA device failover, link failover, and session failover work.

[HA and load balancing](#) describes how FGCP HA active-active load balancing works and how to configure it.

[HA with FortiGate-VM and third-party products](#) describes how FortiGates interact with third-party products.

[VRRP high availability](#) describes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

[FortiGate Session Life Support Protocol \(FGSP\)](#) describes how to use the FGSP feature to support using external routers or load balancers to distribute or load balance sessions between two peer FortiGates.

FortiOS 5.6 HA new features

New high availability features added to FortiOS 5.6.6:

- For FGSP HA, restoring a configuration is not synchronized, see [Backing up and restoring the configuration of an FGSP cluster on page 1997](#).
- [FortiGate-6000 and FortiController-5000 support for VRRP HA on page 1989](#).

New high availability features added to FortiOS 5.6.4:

- FGSP configuration synchronization changes, see [Synchronizing the configuration on page 1995](#).
- Changes to get system status ha command output, see [Viewing cluster status from the CLI on page 1898](#).

New high availability features added to FortiOS 5.6.1:

HA cluster Uptime on HA Status dashboard widget (412089)

The HA Status dashboard widget now displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change.

You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.

FGSP with static (non-dialup) IPsec VPN tunnels and controlling IKE routing advertisement (402295)

Until FortiOS 5.6.1, the FortiGate Session Life Support Protocol (FGSP) only supported IPsec tunnel synchronization for dialup (or dynamic) IPsec VPN tunnels. FortiOS 5.6.1 now also supports IPsec tunnel synchronization for static IPsec VPN tunnels. No special FGSP or IPsec VPN configuration is required. You can configure static IPsec VPN tunnels normally and create a normal FGSP configuration.

An additional feature has been added to support some FGSP configurations that include IPsec VPNs. A new CLI option allows you to control whether IKE routes are synchronized to all units in the FGSP cluster.

```
config system cluster-sync
  edit 0
    set slave-add-ike-routes {enable | disable}
  end
```

Enable to synchronize IKE routes, disable if you do not need to synchronize IKE routes. Enabling routing synchronization is optional but doing so increases synchronization overhead and bandwidth usage. If you have problems with IPsec VPN tunnel synchronization you may want to enable synchronizing routes otherwise you could leave it disabled to improve performance and save bandwidth.

VRRP support for synchronizing firewall VIPs and IP Pools (0397824)

FortiOS VRRP HA now supports failover of firewall VIPs and IP Pools when the status of a virtual router (VR) changes. This feature introduces a new proxy ARP setting to map VIP and IP Pool address ranges to each VR's

Virtual MAC (VMAC). After failover, the IP Ranges added to the new primary VR will be routed to the new primary VR's VMAC.

Use the following command to add a proxy ARP address range and a single IP address to a VR added to a FortiGate's port5 interface. The address range and single IP address should match the address range or single IP for VIPs or IP Pools added to the port5 interface:

```
config system interface
  edit port5
    config vrrp
      edit 1
        config proxy-arp
          edit 1
            set ip 192.168.62.100-192.168.62.200
          next
          edit 2
            set ip 192.168.62.225
          end
```

New high availability features added to FortiOS 5.6.0:

Solving the high availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides six redundancy solutions: industry standard VRRP as well as five proprietary solutions: FortiGate Cluster Protocol (FGCP) high availability, FortiGate Session Life Support Protocol (FGSP) high availability, Session-Aware Load Balancing Clustering (SLBC), Enhanced Load Balanced Clustering (ELBC) and Content Clustering.

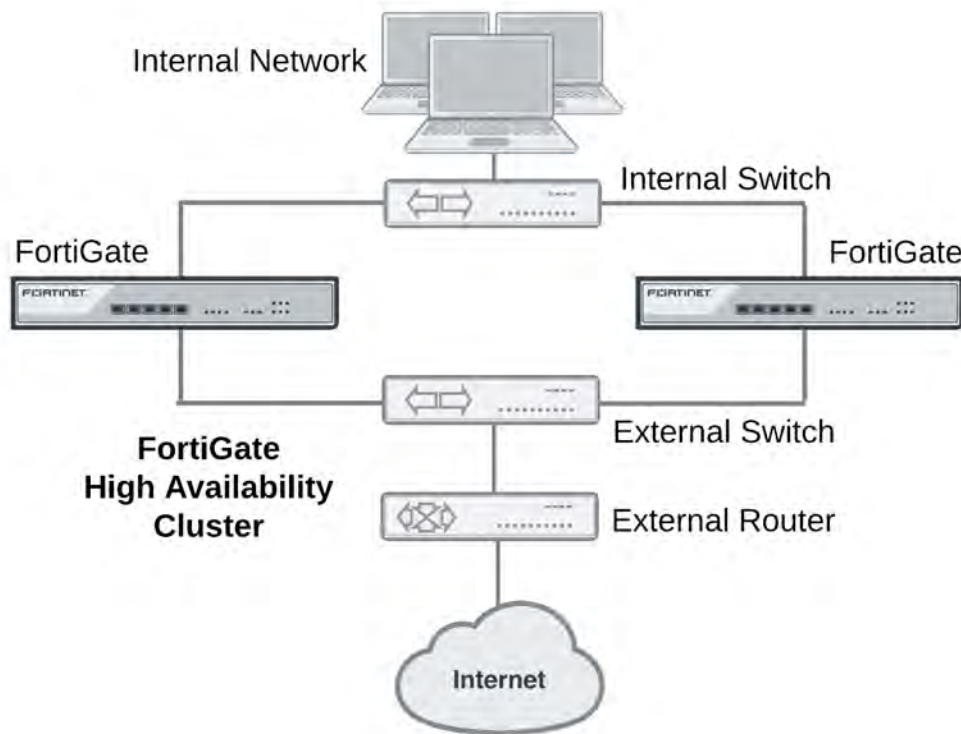

You can combine more than one high availability solution into a single configuration. A common reason for doing this could be to add VRRP to an FGCP or FGSP configuration.

A strong and flexible High availability solution is required for many mission-critical firewall and security profile applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

FortiGate Cluster Protocol (FGCP)

FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection and remote link failover protection. Also contributing to enhanced reliability is session failover protection for most IPv4 and IPv6 sessions including TCP, UDP, ICMP, IPsec VPN, and NAT sessions. Increased performance is achieved through active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

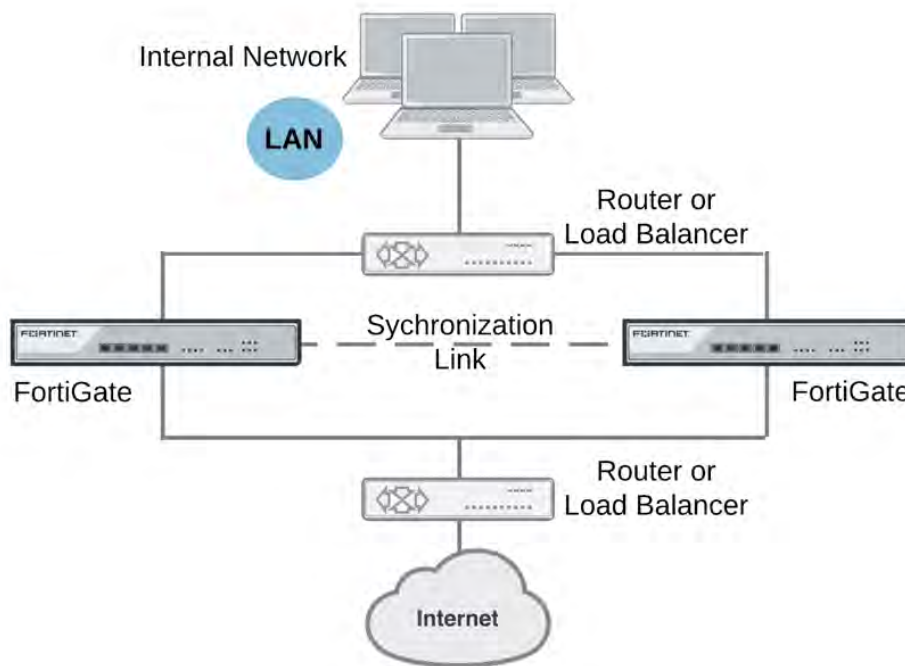

When configured onto your network an FGCP cluster appears to be a single FortiGate operating in NAT or transparent mode and configuration synchronization allows you to configure a cluster in the same way as a standalone FortiGate. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGates can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGates and the FGSP performs session synchronization of IPv4 and IPv6 TCP, SCTP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGates synchronized.

If one of the FortiGates fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGates just perform session synchronization which allows session failover to occur without packet loss.

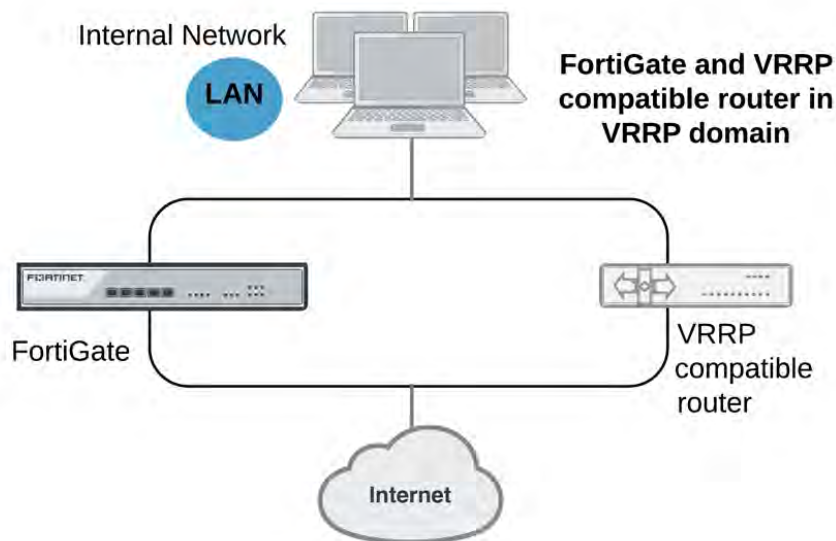

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGates instead of requiring duplicate configuration changes on each unit. However, settings that identify the FortiGate to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate maintains its identity on the network. These settings must be configured separately for each FortiGate.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

VRRP high availability

FortiGates can function as primary (master) or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGates. FortiOS supports VRRP version 2 and 3.

In a VRRP configuration, when a FortiGate operating as the primary router fails, a backup router takes its place and continues processing network traffic. If the backup router is a FortiGate, the network continues to benefit from FortiOS security features. If the backup router is simply a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports IPv4 and IPv6 VRRP between two or more FortiGates and between FortiGates and third-party routers that support VRRP. Using VRRP, you can assign VRRP routers as primary or backup routers. The primary router processes traffic and the backup routers monitor the primary router and can begin forwarding traffic if the primary router fails. Similar to the FGCP, you can set up VRRP among multiple FortiGates to provide redundancy. You can also create a VRRP group with a FortiGate and any routers that support VRRP.

In a VRRP configuration that includes one FortiGate and one router, normally the FortiGate would be the primary router and all traffic would be processed by the FortiGate. If the FortiGate fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features are unavailable until the FortiGate is back on line.

Session-Aware Load Balancing Clustering (SLBC)

Session-Aware Load Balancing Clusters consist of one or more FortiControllers acting as load balancers and two or more FortiGate-5000s and operating as workers all installed in one or two FortiGate-5000 series chassis.

SLBC clusters load balance TCP and UDP sessions. As a session-aware load balancer, the FortiController includes FortiASIC DP processors that maintain state information for all TCP and UDP sessions. The FortiASIC DP processors are capable of directing any TCP or UDP session to any worker installed in the same chassis. This session-awareness means that all TCP and UDP traffic being processed by a specific worker continues to be processed by the same worker. Session-awareness also means that more complex networking features such as network address translation (NAT), fragmented packets, complex UDP protocols, and complex protocols such as SIP that use pinholes, can be load balanced by the cluster.

For more information about SLBC see the *FortiController Session-Aware Load Balancing Guide*.

You cannot mix FGCP and SLBC clusters in the same FortiGate-5000 chassis.

Enhanced Load Balancing Clustering (ELBC)

ELBC uses FortiSwitch-5000 series load balancers to load balance traffic to FortiGate-5000 workers installed in a FortiGate-5000 chassis. ELBC enhances scalability, reliability, and availability of mission critical IP-based services, such as firewall, antivirus, web filtering, IPS, and so on. It also provides high availability by detecting worker failures and automatically redistributing traffic to the workers that are still operating.

ELBC applies a load balancing algorithm against the source and/or destination address of packets to generate a hash key value. Each worker has hash key values assigned to it. If the workers are running, then the traffic is forwarded to the worker assigned to the hash key. The hash key value generated by the algorithm, the hash keys accepted by the worker blades, and the blade the traffic is sent to are automatically calculated by the FortiSwitch.

For more information about ELBC see the *ELBC Configuration Guide*.

You cannot mix FGCP and ELBC clusters in the same FortiGate-5000 chassis.

Content clustering

A content cluster employs FortiSwitch-5203Bs or FortiController-5902Ds to load balance content sessions to FortiGate-5000 workers. FortiSwitch-5203B content clusters consist of one or more FortiSwitch-5203Bs and multiple FortiGate-5001Bs workers. FortiController-5902D content clusters consist of one or more FortiController-5902Ds and multiple FortiGate-5001B workers.

Operating as a FortiGate in content cluster mode, a primary FortiSwitch-5203B or FortiController-5902D performs routing, firewalling, stateful inspection, IPsec and SSL VPN encryption/decryption, and other FortiGate functions. The FortiSwitch-5203B includes NP4 processors and the FortiController-5902Ds includes NP6 processors and an integrated switch fabrics that provides fastpath acceleration by offloading communication sessions from the FortiGate CPU.

Using content cluster weighted load balancing, the FortiSwitch-5203Bs or FortiController-5902Ds distribute sessions that require content processing to the workers over the FortiGate-5000 chassis fabric backplane. Content processing sessions include proxy and flow-based security profile functions such as virus scanning, intrusion protection, application control, IPS, web filtering, email filtering, and VoIP. Load balancing is offloaded to the NP4 or NP6 processors resulting in improved load balancing performance. In some networks, the NP4 or NP6 processors also allow you to configure the efficiently load balance TCP and UDP sessions.

Content cluster mode is similar to active-active HA where the FortiSwitch-5203B or FortiController-5902D operates as the primary unit and load balances security profile sessions to the workers installed in the chassis using weighted load balancing. In this configuration, the HA mode is active-active, the HA load balancing schedule is weight-round-robin and load-balance-all is disabled. You can adjust the HA weighted load balancing weights to change how sessions are load balanced.

You can add a second FortiSwitch-5203B or FortiController-5902D to a content cluster as a backup. The primary FortiSwitch-5203B or FortiController-5902D can load balance sessions to the backup FortiSwitch-5203B or

FortiController-5902D as well as the workers. You can control how many sessions are processed by the backup FortiSwitch-5203B or FortiController-5902D by configuring the HA load balancing weights. You can also configure the content cluster to operate the backup FortiSwitch-5203B or FortiController-5902D in standby mode. In this mode the backup FortiSwitch-5203B or FortiController-5902D does not process any sessions but is just there to take over content clustering if the primary unit fails.

Once the content cluster has been established and all FortiControllers and workers have joined the cluster, you can configure the cluster from the FortiSwitch-5203B or FortiController-5902D GUI or CLI. All configuration changes made to the primary unit are automatically synchronized to all cluster units.

FortiSwitch-5203B or FortiController-5902D firmware upgrades are done from the primary FortiSwitch-5203B or FortiController-5902D GUI or CLI. Worker firmware upgrades are done from the FortiSwitch-5203B or FortiController-5902D CLI where a single firmware image is uploaded once and synchronized to all of the workers.

An introduction to the FGCP

A FortiGate HA cluster consists of two to four FortiGates configured for HA operation. Each FortiGate in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same number of hard disks and so on) and be running in the same operating mode (NAT mode or transparent mode).

You can create an FGCP cluster of up to four FortiGates.

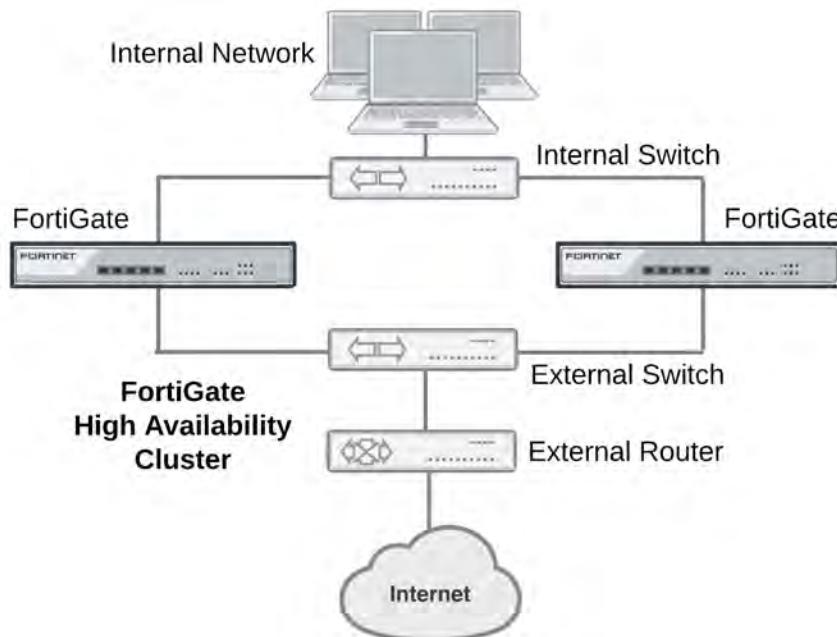

In addition the cluster units must be able to communicate with each other through their heartbeat interfaces. This heartbeat communication is required for the cluster to be created and to continue operating. Without it, the cluster acts like a collection of standalone FortiGates.

On startup, after configuring the cluster units with the same HA configuration and connecting their heartbeat interfaces, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGates configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units over the heartbeat interface link. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat.

The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

About the FGCP

FortiGate HA is implemented by configuring two or more FortiGates to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate, processing network traffic and providing normal security services such as firewalling, security profile services, Security Fabric services, and VPN services.

HA cluster installed between an internal network and the Internet

Inside the cluster the individual FortiGates are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The role that the subordinate units play depends on the mode in which the cluster operates: (Active-Passive (AP) or Active-Active (AA).

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FGCP failover means that your network does not have to rely on one FortiGate to continue functioning. You can install additional units and form an HA cluster.

A second HA feature, called active-active load balancing, can be used to increase performance. An active-active cluster of FortiGates can increase overall network performance by sharing the load of processing network traffic and providing security services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for Virtual Domains (VDOMs). See [Virtual clusters on page 1850](#).

FortiGate models that support redundant interfaces can be configured to support full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see [Full mesh HA on page 1860](#).

FGCP failover protection

The FGCP provides IP/MAC takeover failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking timers, routing table update timers, and wait timers.

An HA cluster fails over if the primary unit fails (a device failure) or experiences a link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

Session failover

FGCP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP, UDP, and ICMP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if it is not required.

Load balancing

Active-active HA load balances resource-intensive security profile features such as virus scanning, web filtering, intrusion protection, application control, email filtering and data leak prevention operations among all cluster units to provide better performance than a standalone FortiGate. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. On some FortiGate models you can also load balance UDP sessions. NP4 and NP6 offloading can accelerate HA load balancing (especially TCP and UDP load balancing). HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGates operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic. It is possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

Full mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a single FortiGate) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a normal FGCP cluster, single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate/redundant interface and HA configurations.

Cluster management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can configure FortiGate features such as firewalling, content inspection, and VPN in the same way as for a standalone FortiGate. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT to transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. A new unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. An extensive range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These message can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units.

Synchronizing the configuration (and settings that are not synchronized)

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units. This includes special configuration settings that include extra information (for example, 3rd party certificates, replacement message text files and graphics and so on).

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate host name. Allows you to identify cluster units.
- The GUI Dashboard configuration. After a failover you may have to re-configure dashboard widgets.
- HA override.
- HA device priority.
- Virtual cluster 1 and Virtual cluster 2 device priorities.
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration.
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface.

- The default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.
- The dynamic weighted load balancing thresholds and high and low watermarks.
- OSPF `summary-addresses` settings.

In addition licenses are not synchronized since each FortiGate must be licensed separately. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS).

Preparing the FortiGates before setting up an FGCP cluster

Before creating an FGCP cluster you should complete the following setup on each FortiGate.

DHCP and PPPoE

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Firmware version

Make sure the FortiGates are running the same FortiOS firmware version.

About HA and licensing

All of the FortiGates in a cluster must have the same level of licensing. This includes licensing for FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMs).

If one of the FortiGates in a cluster has a lower level of licensing than other FortiGates in the cluster, then all of the FortiGates in the cluster will revert to that lower licensing level. For example, if you only purchase FortiGuard Web Filtering for one of the FortiGates in a cluster, when the cluster is operating, none of the cluster units will support FortiGuard Web Filtering.

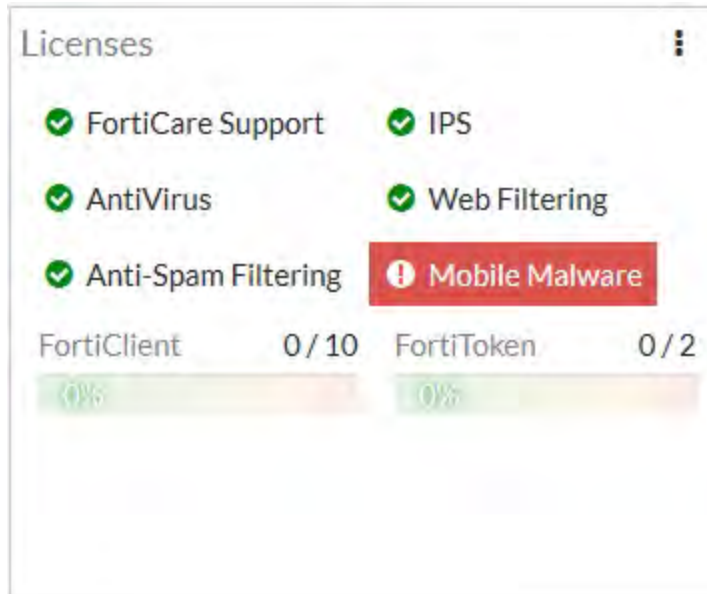

An exception is FortiToken licensing. FortiToken activations are completed one FortiGate unit and synchronized to all of the FortiGates in the cluster.

FortiOS Carrier license

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license. All FortiGates in the cluster must be licensed for FortiOS Carrier.

Support contracts and FortiGuard, FortiCloud, FortiClient, VDOMs licensing

Register and apply these licenses to each FortiGate. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient and VDOMs.

FortiToken licenses

You only need one set of FortiToken licenses for the HA cluster and you only need to activate each token once. Normally you would activate your tokens on the primary unit and this configuration and the seed information will be synchronized to all cluster members so all tokens will then be activated for all cluster members.

If you have added FortiToken licenses and activated FortiTokens on a standalone FortiGate unit before configuring HA, the licenses and the FortiToken activations will usually be synchronized to all cluster units after forming a cluster. To make sure this goes smoothly you can make sure the FortiGate that you have added the licenses to becomes the primary unit when setting up the cluster as described in [How to set up FGCP clustering \(recommended steps\)](#) on page 1771.

Certificates

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.

Configuring FortiGates for FGCP HA operation

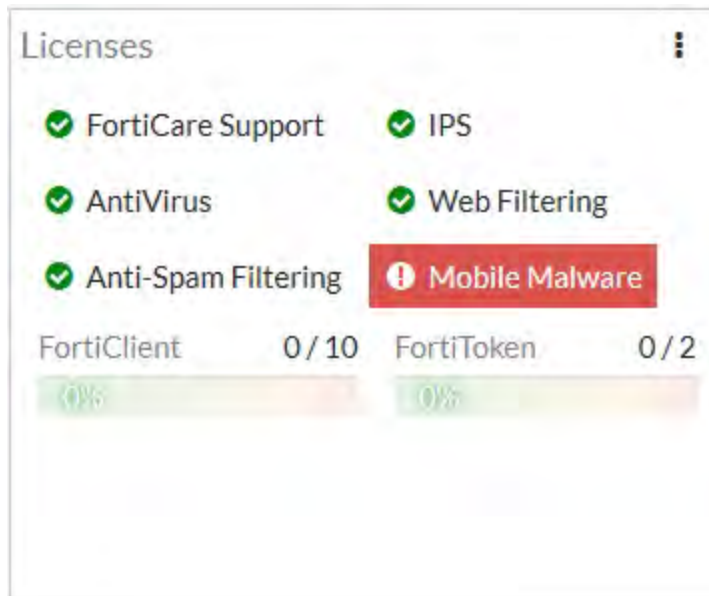

Each FortiGate in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate. The following example sets the HA mode to active-passive and the HA password to HA_pass.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Make sure both FortiGates are running the same FortiOS firmware version. Register and apply licenses to both FortiGates before adding them to the cluster. This includes licensing for FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud, and additional virtual domains (VDOMs). All FortiGates in the

cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. FortiToken licenses can be added at any time because they are synchronized to all cluster members.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

To configure a FortiGate for HA operation - GUI

1. Power on the FortiGate to be configured.
2. Log into the GUI.
3. Locate the System Information Dashboard widget. Click on the System Information dashboard widget and select **Configure settings in System > Settings**.
4. Enter a new Host Name for this FortiGate.
Changing the host name makes it easier to identify individual cluster units when the cluster is operating.
5. Go to **System > HA** and change the following settings:

Mode	Active-Passive
Group Name	Example_cluster
Password	HA_pass
	The password must be the same for all FortiGates in the cluster.

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6. Select **OK**.
The FortiGate negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all ARP table entries). You may be able to delete the ARP table

of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the FortiGate.
8. Repeat this procedure for all of the FortiGates in the cluster.
Once all of the units are configured, continue by connecting the FortiGate HA cluster below.

To configure a FortiGate for HA operation - CLI

1. Power on the FortiGate to be configured.
2. Log into the CLI.
3. Enter the following command to change the FortiGate host name.

```
config system global
  set hostname Example1_host
end
```

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

4. Enter the following command to enable HA:

```
config system ha
  set mode active-passive
  set group-name Example_cluster
  set password HA_pass
end
```

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5. Power off the FortiGate.
6. Repeat this procedure for all of the FortiGates in the cluster.
Once all of the units are configured, continue with connecting the FortiGate HA cluster.

Connecting a FortiGate HA cluster

Use the following procedure to connect a cluster. Connect the cluster units to each other and to your network. You must connect all matching interfaces in the cluster to the same switch, then connect these interfaces to their networks using the same switch.

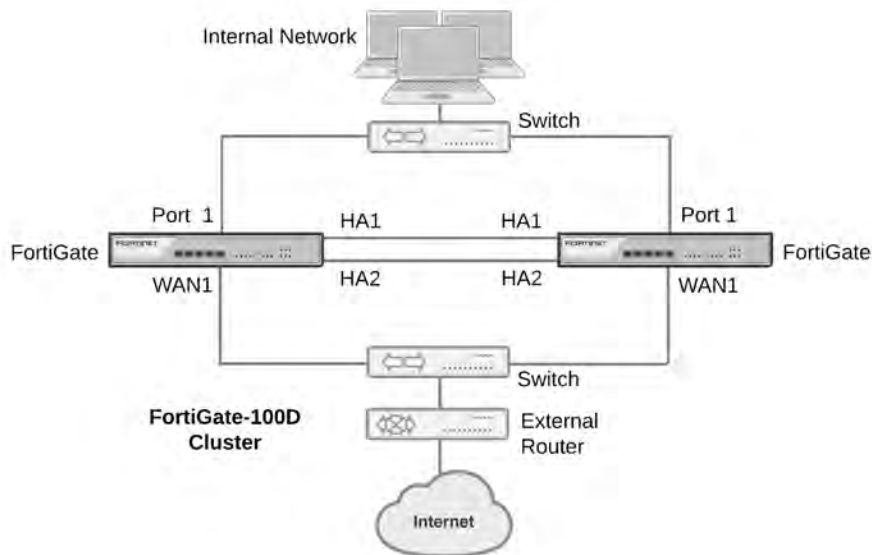

Although you can use hubs, Fortinet recommends using switches for all cluster connections for the best performance.

Connecting an HA cluster to your network temporarily interrupts communications on the network because new physical connections are being made to route traffic through the cluster. Also, starting the cluster interrupts network traffic until the individual cluster units are functioning and the cluster completes negotiation. Cluster negotiation is automatic and normally takes just a few seconds. During system startup and negotiation all network traffic is dropped.

This section describes how to connect the cluster shown below, which consists of two FortiGate-100D units to be connected between the Internet and a head office internal network. The wan1 interfaces of the FortiGate connect

the cluster to the Internet and the internal interfaces connect the cluster to the internal network. The ha1 and ha2 interfaces are used for redundant HA heartbeat links.

Example cluster connections

To connect a FortiGate HA cluster

1. Connect the WAN1 interfaces of each cluster unit to a switch connected to the Internet.
2. Connect the Port1 interfaces of each cluster unit to a switch connected to the internal network.
3. Connect the HA1 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
4. Connect the HA2 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
5. Power on both of the FortiGates.

As the cluster units start, they negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally just takes a few seconds.

At least one heartbeat interface should be connected together for the cluster to operate.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

You could use one switch to connect all four heartbeat interfaces. However, this is not recommended because if the switch fails both heartbeat interfaces will become disconnected.

6. You can now configure the cluster as if it is a single FortiGate.

Verifying the cluster status from the HA Status dashboard widget

The HA Status dashboard widget shows the mode and group names of the cluster, the status of the cluster units and their hostnames, the cluster uptime and the last time the cluster state changed. A state change can indicate the cluster first forming or one of the cluster units changing its role in the cluster.

The HA Status Dashboard widget also shows if the cluster units are synchronized. Mouse over each FortiGate in the cluster to verify that they both have the same checksum.

From the HA Status widget you can also select **Show HA Historical Events** to see the most recent HA system status messages.

HA Historical Events		
#	Date/Time	Event
1	10-05 14:41	FGT6HD3916800525 is elected as the cluster master of 2 members
2	10-05 14:41	new member 'FGT6HD3916801195' joins the cluster
3	10-05 14:41	hbdev port4 link status changed: 0->1
4	10-05 14:41	port port4 link status changed: 0->1
5	10-05 14:41	hbdev port4 link status changed: 1->0
6	10-05 14:41	port port4 link status changed: 1->0

Active-passive and active-active HA

The first decision to make when configuring FortiGate HA is whether to choose active-passive or active-active HA mode. To configure the HA mode, go to **System > HA** and set Mode to **Active-Passive** or **Active-Active**.

From the CLI enter the following command to set the HA mode to active-passive:

```
config system ha
  set mode a-p
end
```

To form a cluster, all cluster units must be set to the same mode. You can also change the mode after the cluster is up and running. Changing the mode of a functioning cluster causes a slight delay while the cluster renegotiates to operate in the new mode and possibly select a new primary unit.

Active-passive HA (failover protection)

An active-passive (A-P) HA cluster provides hot standby failover protection. An active-passive cluster consists of a primary unit that processes communication sessions, and one or more subordinate units. The subordinate units are connected to the network and to the primary unit but do not process communication sessions. Instead, the subordinate units run in a standby state. In this standby state, the configuration of the subordinate units is synchronized with the configuration of the primary unit and the subordinate units monitor the status of the primary unit.

Active-passive HA provides transparent device failover among cluster units. If a cluster unit fails, another immediately take its place.

Active-passive HA also provides transparent link failover among cluster units. If a cluster unit interface fails or is disconnected, this cluster unit updates the link state database and the cluster negotiates and may select a new primary unit.

If session failover (also called session pickup) is enabled, active-passive HA provides session failover for some communication sessions.

The following example shows how to configure a FortiGate for active-passive HA operation. You would enter the exact same commands on every FortiGate in the cluster.

```
config system ha
  set mode a-p
  set group-name myname
  set password HApass
end
```

Active-active HA (load balancing and failover protection)

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Normally, sessions accepted by policies that don't include security profiles are not load balanced and are processed by the primary unit. You can configure active-active HA to load balance additional sessions.

An active-active HA cluster consists of a primary unit that receives all communication sessions and load balances them among the primary unit and all of the subordinate units. In an active-active cluster the subordinate units are also considered active since they also process content processing sessions. In all other ways active-active HA operates the same as active-passive HA.

The following example shows how to configure a FortiGate for active-active HA operation. You would enter the exact same commands on every FortiGate in the cluster.

```
config system ha
  set mode a-a
  set group-name myname
  set password HApass
end
```

Identifying the cluster and cluster units

You can use the cluster group name, group id, and password to identify a cluster and distinguish one cluster from another. If you have more than one cluster on the same network, each cluster must have a different group name, group id, and password.

Group name

Use the group name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units. The group name appears on the HA Status dashboard widget.

To add or change the group name from the GUI go to **System > HA** and change the **Group name**.

Enter the following CLI command to change the group name to Cluster_name:

```
config system ha
  set group-name Cluster_name
end
```

Password

Use the password to identify the cluster. You should always change the password when configuring a cluster. The password must be the same for all FortiGates before they can form a cluster. When the cluster is operating you can change the password, if required. Two clusters on the same network cannot have the same password.

To change the password from the GUI go to **System > HA** and change the **Password**.

Enter the following CLI command to change the password to ha_pwd:

```
config system ha
  set password ha_pwd
end
```

Group ID

Similar to the group name, the group ID is also identifies the cluster. In most cases you do not have to change the group ID. However, you should change the group ID if you have more than one cluster on the same network. All members of the HA cluster must have the same group ID. The group ID is a number from 0 to 255.

Changing the group ID changes the cluster virtual MAC address. If two clusters on the same network have the same group ID you may encounter MAC address conflicts.

Enter the following CLI command to change the group ID to 10:

```
config system ha
  set group-id 10
end
```

Device failover, link failover, and session failover

The FGCP provides transparent device and link failover. You can also enable session pickup to provide session failover. A failover can be caused by a hardware failure, a software failure, or something as simple as a network cable being disconnected causing a link failover. When a failover occurs, the cluster detects and recognizes the failure and takes steps to respond so that the network can continue to operate without interruption. The internal operation of the cluster changes, but network components outside of the cluster notice little or no change.

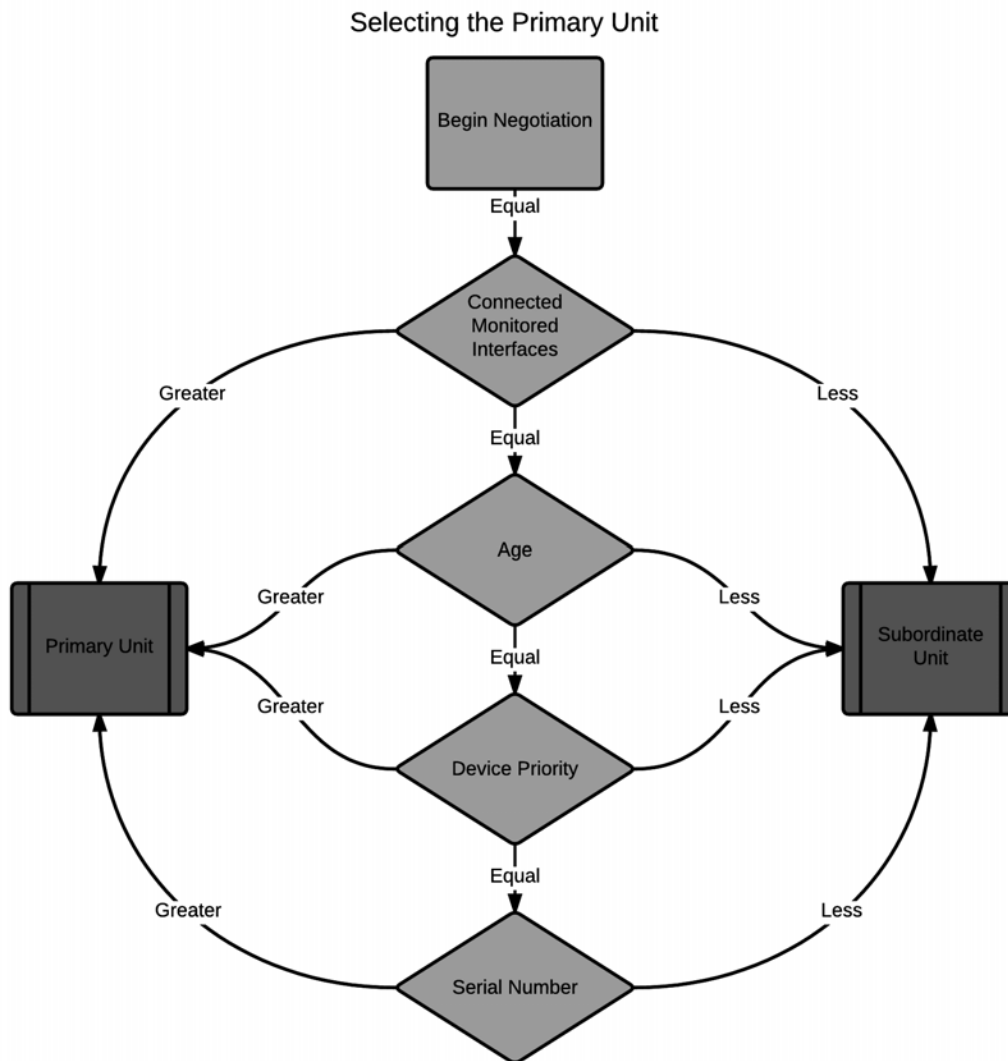

If a failover occurs, the cluster also records log messages about the event and can be configured to send log messages to a syslog server and to a FortiAnalyzer unit. The cluster can also send SNMP traps and alert email messages. These alerts can notify network administrators of the failover and may contain information that the network administrators can use to find and fix the problem that caused the failure.

For a complete description of device failover, link failover, and session failover, how clusters support these types of failover, and how FortiGate HA clusters compensate for a failure to maintain network traffic flow see [HA and failover protection on page 1909](#).

Primary unit selection

Once FortiGates recognize that they can form a cluster, the cluster units negotiate to select a primary unit. Primary unit selection occurs automatically based on the criteria shown below. After the cluster selects the primary unit, all of the remaining cluster units become subordinate units.

Negotiation and primary unit selection also takes place if a primary unit fails (device failover) or if a monitored interface fails or is disconnected (link failover). During a device or link failover, the cluster renegotiates to select a new primary unit also using the criteria shown below.

For many basic HA configurations primary unit selection simply selects the cluster unit with the highest serial number to become the primary unit. A basic HA configuration involves setting the HA mode to active-passive or active-active and configuring the cluster group name and password. Using this configuration, the cluster unit with the highest serial number becomes the primary unit because primary unit selection disregards connected monitored interfaces (because interface monitoring is not configured), the age of the cluster units would usually always be the same, and all units would have the same device priority.

Using the serial number is a convenient way to differentiate cluster units; so basing primary unit selection on the serial number is predictable and easy to understand and interpret. Also the cluster unit with the highest serial number would usually be the newest FortiGate with the most recent hardware version. In many cases you may not need active control over primary unit selection, so basic primary unit selection based on serial number is sufficient.

In some situations you may want have control over which cluster unit becomes the primary unit. You can control primary unit selection by setting the device priority of one cluster unit to be higher than the device priority of all other cluster units. If you change one or more device priorities, during negotiation, the cluster unit with the

highest device priority becomes the primary unit. As shown above, the FGCP selects the primary unit based on device priority before serial number. For more information about how to use device priorities, see [Primary unit selection and device priority on page 1750](#).

The only other way that you can influence primary unit selection is by configuring interface monitoring (also called port monitoring). Using interface monitoring you can make sure that cluster units with failed or disconnected monitored interfaces cannot become the primary unit. See [Primary unit selection and monitored interfaces on page 1747](#).

Finally, the age of a cluster unit is determined by a number of operating factors. Normally the age of all cluster units is the same so normally age has no effect on primary unit selection. Age does affect primary unit selection after a monitored interface failure. For more information about age, see [Primary unit selection and age on page 1747](#).

Viewing how the primary unit was selected

You can use the `get system ha status` command to see how the primary unit was selected. The output of this command contains a section called `Master selected using` that shows a history of how the primary unit was selected. For example, when a cluster first forms this part of the command output could have one line showing that the primary unit is the cluster unit with the highest uptime.

```
get system ha status
.
.
.
Master selected using:
    <2016/10/12 11:13:23> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
.
.
.
```

Over time more messages could be added as the cluster negotiates to choose a new primary unit on different occasions. The command output below shows the cluster negotiated four times over a few days.

```
get system ha status
.
.
.
Master selected using:
    <2016/10/16 11:36:07> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
    <2016/10/15 11:24:11> FG-5KD3914800284 is selected as the master because it
has the largest value of override priority.
    <2016/10/13 11:15:13> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
    <2016/10/11 11:13:23> FG-5KD3914800344 is selected as the master because it
has the largest value of uptime.
.
.
.
```

Primary unit selection and monitored interfaces

If you have configured interface monitoring the cluster unit with the highest number of monitored interfaces that are connected to networks becomes the primary unit. Put another way, the cluster unit with the highest number of failed or disconnected monitored interfaces cannot become the primary unit.

Normally, when a cluster starts up, all monitored interfaces of all cluster units are connected and functioning normally. So monitored interfaces do not usually affect primary unit selection when the cluster first starts.

A cluster always renegotiates when a monitored interface fails or is disconnected (called link failover). A cluster also always renegotiates when a failed or disconnected monitored interface is restored.

If a primary unit monitored interface fails or is disconnected, the cluster renegotiates and if this is the only failed or disconnected monitored interface the cluster selects a new primary unit.

If a subordinate unit monitored interface fails or is disconnected, the cluster also renegotiates but will not necessarily select a new primary unit. However, the subordinate unit with the failed or disconnected monitored interface cannot become the primary unit.

Multiple monitored interfaces can fail or become disconnected on more than one cluster unit. Each time a monitored interface is disconnected or fails, the cluster negotiates to select the cluster unit with the most connected and operating monitored interfaces to become the primary unit. In fact, the intent of the link failover feature is just this, to make sure that the primary unit is always the cluster unit with the most connected and operating monitored interfaces.

Primary unit selection and age

The cluster unit with the highest age value becomes the primary unit. The age of a cluster unit is the amount of time since a monitored interface failed or is disconnected. Age is also reset when a cluster unit starts (boots up). So, when all cluster units start up at about the same time, they all have the same age. Age does not affect primary unit selection when all cluster units start up at the same time. Age also takes precedence over priority for primary unit selection.

If a link failure of a monitored interface occurs, the age value for the cluster unit that experiences the link failure is reset. So, the cluster unit that experienced the link failure also has a lower age value than the other cluster units. This reduced age does not effect primary unit selection because the number of link failures takes precedence over the age.

If the failed monitored interface is restored the cluster unit that had the failed monitored interface cannot become the primary unit because its age is still lower than the age of the other cluster units.

In most cases, the way that age is handled by the cluster reduces the number of times the cluster selects a new primary unit, which results in a more stable cluster since selecting a new primary unit has the potential to disrupt traffic.

Cluster age difference margin (grace period)

In any cluster, some of the cluster units may take longer to start up than others. This startup time difference can happen as a result of a number of issues and does not affect the normal operation of the cluster. To make sure that cluster units that start slower can still become primary units, by default the FGCP ignores age differences of up to 5 minutes (300 seconds).

In most cases, during normal operation this age difference margin or grace period helps clusters function as expected. However, the age difference margin can result in some unexpected behavior in some cases:

- During a cluster firmware upgrade with `uninterruptible-upgrade` enabled (the default configuration) the cluster should not select a new primary unit after the firmware of all cluster units has been updated. But since the age difference of the cluster units is most likely less than 300 seconds, age is not used to affect primary unit selection and the cluster may select a new primary unit.
- During failover testing where cluster units are failed over repeatedly the age difference between the cluster units will most likely be less than 5 minutes. During normal operation, if a failover occurs, when the failed unit rejoins the cluster its age will be very different from the age of the still operating cluster units so the cluster will not select a new primary unit. However, if a unit fails and is restored in a very short time the age difference may be less than 5 minutes. As a result the cluster may select a new primary unit during some failover testing scenarios.

Changing the cluster age difference margin

You can change the cluster age difference margin using the following command:

```
config system ha
    set ha-uptime-diff-margin 60
end
```

This command sets the cluster age difference margin to 60 seconds (1 minute). The age difference margin range is 1 to 65535 seconds. The default is 300 seconds.

You may want to reduce the margin if during failover testing you don't want to wait the default age difference margin of 5 minutes. You may also want to reduce the margin to allow uninterruptible upgrades to work. See [Operating clusters and virtual clusters on page 1874](#).

You may want to increase the age margin if cluster unit startup time differences are larger than 5 minutes.

Displaying cluster unit age differences

You can use the CLI command `diagnose sys ha dump-by group` to display the age difference of the units in a cluster. This command also displays information about a number of HA-related parameters for each cluster unit.

For example, consider a cluster of two FortiGate-600D units. Entering the `diagnose sys ha dump-by group` command from the primary unit CLI displays information similar to the following:

```
diagnose sys ha dump-by group
    HA information.
group-id=0, group-name='External-HA-Cluster'

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
linkfails=11, weight/o=0/0
    hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac=
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
    'FGT6HD3916801955': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
    'FGT6HD3916800525': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000001, uptime/reset_cnt=189/0
```

The last two lines of the output display status information about each cluster unit including the `uptime`. The `uptime` is the age difference in seconds between the two units in the cluster.

In the example, the age of the subordinate unit is 189 seconds more than the age of the primary unit. The age difference is less than 5 minutes (less than 300 seconds) so age has no affect on primary unit selection. The cluster selected the unit with the highest serial number to be the primary unit.

If port1 (the monitored interface) of the primary unit is disconnected, the cluster renegotiates and the former subordinate unit becomes the primary unit. When you log into the new primary unit CLI and enter `diagnose sys ha dump-by group` you could get results similar to the following:

```
diagnose sys ha dump-by group
      HA information.
group-id=0, group-name='External-HA-Cluster'

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
linkfails=11, weight/o=0/0
      hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac-
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
      'FGT6HD3916800525': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
      'FGT6HD3916801195': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000001, uptime/reset_cnt=236/0
```

The command results show that the age of the new primary unit is 236 seconds higher than the age of the new subordinate unit.

If port1 of the former primary unit is reconnected the cluster will once again make this the primary unit because the age difference will still be less than 300 seconds. When you log into the primary unit CLI and enter `diagnose sys ha dump-by group` you get results similar to the following:

```
diagnose sys ha dump-by group
      HA information.
group-id=0, group-name='External-HA-Cluster'

gmember_nr=2
'FGT6HD3916800525': ha_ip_idx=1, hb_packet_version=6, last_hb_jiffies=52097155,
linkfails=11, weight/o=0/0
      hbdev_nr=2: port3(mac=906c..70, last_hb_jiffies=52097155, hb_lost=0), port4(mac-
c=906c..71, last_hb_jiffies=52097155, hb_lost=0),
'FGT6HD3916801195': ha_ip_idx=0, hb_packet_version=6, last_hb_jiffies=0, link-
fails=0, weight/o=0/0

vcluster_nr=1
vcluster_0: start_time=1507754642(2017-10-11 13:44:02), state/o/chg_time=2(work)/2
(work)/1507754644(2017-10-11 13:44:04)
      'FGT6HD3916800525': ha_prio/o=1/1, link_failure=0(old=0), pingsvr_failure=0, flag-
g=0x00000000, uptime/reset_cnt=0/1
```

```
'FGT6HD3916801955': ha_prio/o=0/0, link_failure=0(old=0), pingsvr_failure=0, flag-  
g=0x00000001, uptime/reset_cnt=-236/0
```

Resetting the age of all cluster units

In some cases, age differences among cluster units can result in the wrong cluster unit or the wrong virtual cluster becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units when it rejoins the cluster. Since age takes precedence over priority, the priority of this cluster unit will not be a factor in primary unit selection.

This problem also affects virtual cluster VDOM partitioning in a similar way. After a reboot of one of the units in a virtual cluster configuration, traffic for all VDOMs could continue to be processed by the cluster unit that did not reboot. This can happen because the age of both virtual clusters on the unit that did not reboot is greater than the age of both virtual clusters on the unit that rebooted.

One way to resolve this issue is to reboot all of the cluster units at the same time so that the age of all of the cluster units is reset. However, rebooting cluster units may interrupt or at least slow down traffic. If you would rather not reboot all of the cluster units you can instead use the following command to reset the age of individual cluster units.

```
diagnose sys ha reset-uptime
```

This command resets the age of a unit back to zero so that if no other unit in the cluster was reset at the same time, it will now have the lowest age. You would use this command to reset the age of the cluster unit that is currently the primary unit. Since it will have the lowest age, the other unit in the cluster will have the highest age and can then become the primary unit.

The `diagnose sys ha reset-uptime` command should only be used as a temporary solution. The command resets the HA age internally and does not affect the up time displayed for cluster units using the `diagnose sys ha dump-by all-vcluster` command or the up time displayed on the Dashboard or cluster members list. To make sure the actual up time for cluster units is the same as the HA age you should reboot the cluster units during a maintenance window.

Primary unit selection and device priority

A cluster unit with the highest device priority becomes the primary unit when the cluster starts up or renegotiates. By default, the device priority for all cluster units is 128. You can change the device priority to control which FortiGate becomes the primary unit during cluster negotiation. All other factors that influence primary unit selection either cannot be configured (age and serial number) or are synchronized among all cluster units (interface monitoring). You can set a different device priority for each cluster unit. During negotiation, if all monitored interfaces are connected, and all cluster units enter the cluster at the same time (or have the same age), the cluster with the highest device priority becomes the primary unit.

A higher device priority does not affect primary unit selection for a cluster unit with the most failed monitored interfaces or with an age that is higher than all other cluster units because failed monitored interfaces and age are used to select a primary unit before device priority.

Increasing the device priority of a cluster unit does not always guarantee that this cluster unit will become the primary unit. During cluster operation, an event that may affect primary unit selection may not always result in the cluster renegotiating. For example, when a unit joins a functioning cluster, the cluster will not renegotiate. So if a unit with a higher device priority joins a cluster the new unit becomes a subordinate unit until the cluster renegotiates.

Enabling the `override` HA CLI keyword makes changes in device priority more effective by causing the cluster to negotiate more often to make sure that the primary unit is always the unit with the highest device priority. For more information about `override`, see [Primary unit selection on page 1744](#).

Controlling primary unit selection by changing the device priority

You set a different device priority for each cluster unit to control the order in which cluster units become the primary unit when the primary unit fails.

To change the device priority from the GUI go to **System > HA** and change the **Device priority**.

Enter the following CLI command to change the device priority to 200:

```
config system ha
  set priority 200
end
```

The device priority is not synchronized among cluster units. In a functioning cluster you can change the device priority of any unit in the cluster. Whenever you change the device priority of a cluster unit, when the cluster negotiates, the unit with the highest device priority becomes the primary unit.

The following example shows how to change the device priority of a subordinate unit to 255 so that this subordinate unit becomes the primary unit. You can change the device priority of a subordinate unit by going to **System > HA** and selecting the Edit icon for the subordinate unit. Or from the CLI you can use the `execute ha manage 0` command to connect to the highest priority subordinate unit. After you enter the following commands the cluster renegotiates and selects a new primary unit.

```
execute ha manage 1
config system ha
  set priority 255
end
```

If you have three units in a cluster you can set the device priorities as shown below. When the cluster starts up, cluster unit A becomes the primary unit because it has the highest device priority. If unit A fails, unit B becomes the primary unit because unit B has a higher device priority than unit C.

Example device priorities for a cluster of three FortiGates

Cluster unit	Device priority
A	200
B	100
C	50

When configuring HA you do not have to change the device priority of any of the cluster units. If all cluster units have the same device priority, when the cluster first starts up the FGCP negotiates to select the cluster unit with the highest serial number to be the primary unit. Clusters also function normally if all units have the same device priority.

You can change the device priority if you want to control the roles that individual units play in the cluster. For example, if you want the same unit to always become the primary unit, set this unit device priority higher than the

device priority of other cluster units. Also, if you want a cluster unit to always become a subordinate unit, set this cluster unit device priority lower than the device priority of other cluster units.

If you have a cluster of three units you can set a different priority for each unit to control which unit becomes the primary unit when all three cluster units are functioning and which will be the primary unit when two cluster units are functioning.

The device priority range is 0 to 255. The default device priority is 128.

If you are configuring a virtual cluster, if you have added virtual domains to both virtual clusters, you can set the device priority that the cluster unit has in virtual cluster 1 and virtual cluster 2. If a FortiGate has different device priorities in virtual cluster 1 and virtual cluster 2, the FortiGate may be the primary unit in one virtual cluster and the subordinate unit in the other.

Primary unit selection and the FortiGate serial number

The cluster unit with the highest serial number is more likely to become the primary unit. When first configuring FortiGates to be added to a cluster, if you do not change the device priority of any cluster unit, then the cluster unit with the highest serial number always becomes the primary unit.

Age does take precedence over serial number, so if a cluster unit takes longer to join a cluster for some reason (for example if one cluster unit is powered on after the others), that cluster unit will not become the primary unit because the other units have been in the cluster longer.

Device priority and failed monitored interfaces also take precedence over serial number. A higher device priority means a higher priority. So if you set the device priority of one unit higher or if a monitored interface fails, the cluster will not use the FortiGate serial number to select the primary unit.

Points to remember about primary unit selection

Some points to remember about primary unit selection:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored interfaces > Age > Device Priority > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered if a cluster unit fails or if a monitored interface fails.
- If the HA age difference is more than 5 minutes (300 seconds), the cluster unit that is operating longer becomes the primary unit.
- If HA age difference is less than 5 minutes (300 seconds), the device priority and FortiGate serial number selects the cluster unit to become the primary unit.
- Every time a monitored interface fails the HA age of the cluster unit is reset to 0.
- Every time a cluster unit restarts the HA age of the cluster unit is reset to 0.

HA override

The HA `override` CLI keyword is disabled by default. When `override` is disabled a cluster may not always renegotiate when an event occurs that affects primary unit selection. For example, when `override` is disabled a cluster will not renegotiate when you change a cluster unit device priority or when you add a new cluster unit to a cluster. This is true even if the unit added to the cluster has a higher device priority than any other unit in the cluster. Also, when `override` is disabled a cluster does not negotiate if the new unit added to the cluster has a failed or disconnected monitored interface.

For a virtual cluster configuration, `override` is enabled by default for both virtual clusters when you enable virtual cluster 2. For more information, see [Virtual clusters on page 1850](#).

In most cases you should keep `override` disabled to reduce how often the cluster negotiates. Frequent negotiations may cause frequent traffic interruptions.

However, if you want to make sure that the same cluster unit always operates as the primary unit and if you are less concerned about frequent cluster negotiation you can set its device priority higher than other cluster units and enable `override`.

To enable `override`, connect to each cluster unit CLI (using the `execute ha manage` command) and use the `config system ha` CLI command to enable `override`.

For `override` to be effective, you must also set the device priority highest on the cluster unit that you want to always be the primary unit. To increase the device priority, from the CLI use the `config system ha` command and increase the value of the `priority` keyword to a number higher than the default priority of 128.

You can also increase the device priority from the GUI by going to **System > HA**. To increase the device priority of the primary unit select edit for the primary or subordinate unit and set the **Device Priority** to a number higher than 128.

The `override` setting and device priority value are not synchronized to all cluster units. You must enable `override` and adjust device priority manually and separately for each cluster unit.

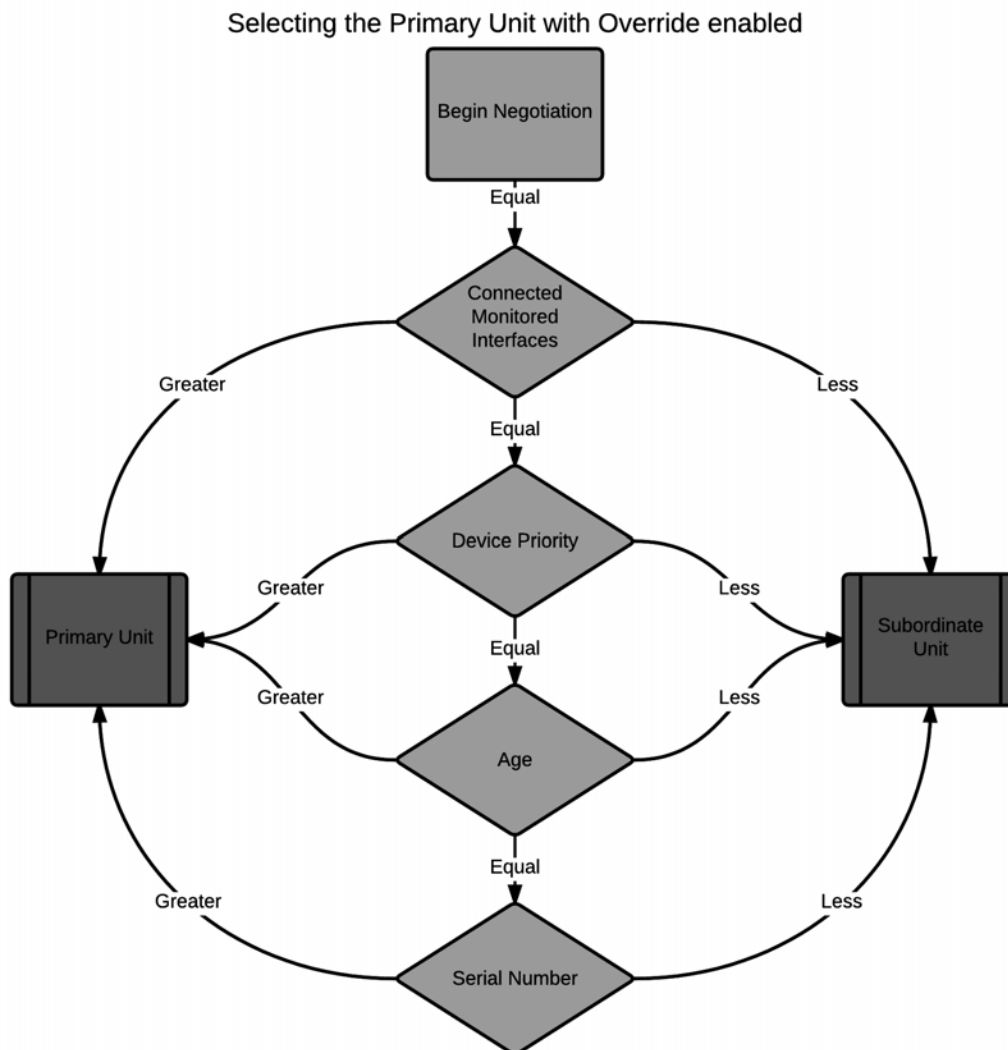

With `override` enabled, the primary unit with the highest device priority will always become the primary unit. Whenever an event occurs that may affect primary unit selection, the cluster negotiates. For example, when `override` is enabled a cluster renegotiates when you change the device priority of any cluster unit or when you add a new unit to a cluster.

Override and primary unit selection

Enabling `override` changes the order of primary unit selection. As shown below, if `override` is enabled, primary unit selection considers device priority before age and serial number. This means that if you set the device priority higher on one cluster unit, with `override` enabled this cluster unit becomes the primary unit even if its age and serial number are lower than other cluster units.

Similar to when `override` is disabled, when `override` is enabled primary unit selection checks for connected monitored interfaces first. So if interface monitoring is enabled, the cluster unit with the most disconnected monitored interfaces cannot become the primary unit, even if the unit has the highest device priority.

If all monitored interfaces are connected (or interface monitoring is not enabled) and the device priority of all cluster units is the same then age and serial number affect primary unit selection.

Controlling primary unit selection using device priority and override

To configure one cluster unit to always become the primary unit you should set its device priority to be higher than the device priorities of the other cluster units and you should enable `override` on all cluster units.

Using this configuration, when the cluster is operating normally the primary unit is always the unit with the highest device priority. If the primary unit fails the cluster renegotiates to select another cluster unit to be the primary unit. If the failed primary unit recovers, starts up again and rejoins the cluster, because `override` is enabled, the cluster renegotiates. Because the restarted primary unit has the highest device priority it once again becomes the primary unit.

In the same situation with `override` disabled, because the age of the failed primary unit is lower than the age of the other cluster units, when the failed primary unit rejoins the cluster it does not become the primary unit. Instead, even though the failed primary unit may have the highest device priority it becomes a subordinate unit because its age is lower than the age of all the other cluster units.

Points to remember about primary unit selection when override is enabled

Some points to remember about primary unit selection when `override` is enabled:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored Interfaces > Device Priority > Age > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered whenever an event occurs which may affect primary unit selection. For example negotiation occurs, when you change the device priority, when you add a new unit to a cluster, if a cluster unit fails, or if a monitored interface fails.
- Device priority is considered before age. Otherwise age is handled the same when `override` is enabled.

Configuration changes can be lost if override is enabled

In some cases, when `override` is enabled and you make configuration changes to an HA cluster these changes can be lost. For example, consider the following sequence:

1. A cluster of two FortiGates is operating with `override` enabled.
 - FGT-A: Primary unit with device priority 200 and with `override` enabled
 - FGT-B: Subordinate unit with device priority 100 and with `override` disabled
 - If both units are operating, FGT-A always becomes the primary unit because FGT-A has the highest device priority.
2. FGT-A fails and FGT-B becomes the new primary unit.
3. The administrator makes configuration changes to the cluster.

The configuration changes are made to FGT-B because FGT-B is operating as the primary unit. These configuration changes are not synchronized to FGT-A because FGT-A is not operating.
4. FGT-A is restored and starts up again.
5. The cluster renegotiates and FGT-A becomes the new primary unit.
6. The cluster recognizes that the configurations of FGT-A and FGT-B are not the same.
7. The configuration of FGT-A is synchronized to FGT-B.

The configuration is always synchronized from the primary unit to the subordinate units.
8. The cluster is now operating with the same configuration as FGT-A. The configuration changes made to FGT-B have been lost.

The solution

When `override` is enabled, you can prevent configuration changes from being lost by doing the following:

- Verify that all cluster units are operating before making configuration changes (from the GUI go to **System > HA** to view the cluster members list or from the FortiOS CLI enter `get system ha status`).
- Make sure the device priority of the primary unit is set higher than the device priorities of all other cluster units before making configuration changes.
- Disable `override` either permanently or until all configuration changes have been made and synchronized to all cluster units.

Override and disconnecting a unit from a cluster

A similar scenario to that described above may occur when `override` is enabled and you use the Disconnect from Cluster option from the GUI or the `execute ha disconnect` command from the CLI to disconnect a cluster unit from a cluster.

Configuration changes made to the cluster can be lost when you reconnect the disconnected unit to the cluster. You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. Otherwise, when the disconnected unit joins the cluster, if `override` is enabled, the cluster renegotiates and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units and any configuration changes made between when the unit was disconnected and reconnected are lost.

Delaying how quickly the primary unit rejoins the cluster when override is enabled

In some cases when override is enabled and the unit designated to be the primary unit rejoins the cluster it will become the primary unit too soon and cause traffic disruption. This can happen, for example, if one of the FortiGate interfaces gets its address using PPPoE. If the backup unit is operating as the primary unit and processing traffic, when the primary unit comes up it may need a short time to get a new IP address from the PPPoE server. If the primary unit takes over the cluster before it has an IP address, traffic will be disrupted until the primary unit gets its address.

You can resolve this problem by using the following command to add a wait time. In this example the wait time is 10 seconds. The wait time range is 0 to 3600 seconds and the default wait time is 0 seconds.

```
config system ha
    set override-wait-time 10
end
```

With this wait time configured, after the primary unit is up and running it has 10 seconds to synchronize sessions, get IP address(es) from PPPoE and DHCP servers and so on. After 10 seconds the primary unit sends gratuitous arp packets and all traffic to the cluster is sent to the new primary unit. You can adjust the wait time according to the conditions on your network.

FortiGate HA compatibility with DHCP and PPPoE

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

You cannot switch to operate in HA mode if one or more FortiGate interfaces is configured as a PPTP or L2TP client.

You can configure a cluster to act as a DHCP server or a DHCP relay agent. In both active-passive and active-active clusters DHCP relay sessions are always handled by the primary unit. It is possible that a DHCP relay session could be interrupted by a failover. If this occurs the DHCP relay session is not resumed after the failover and the DHCP client may have to repeat the DHCP request.

When a cluster is operating as a DHCP server the primary unit responds to all DHCP requests and maintains the DHCP server address lease database. The cluster also dynamically synchronizes the DHCP server address lease database to the subordinate units. If a failover occurs, the new primary unit will have an up-to-date DHCP server address lease database. Synchronizing the DHCP address lease database prevents the new primary unit from responding incorrectly to new DHCP requests after a failover.

Also, it is possible that when FortiGates first negotiate to form a cluster that a unit that ends up as a subordinate unit in the cluster will have information in its DHCP address lease database that the cluster unit operating as the

primary unit does not have. This can happen if a FortiGate responds to DHCP requests while operating as a standalone unit and then when the cluster is formed this unit becomes a subordinate unit. Because of this possibility, after a cluster is formed the DHCP address lease databases of all of the cluster units are merged into one database which is then synchronized to all cluster units.

HA and distributed clustering

The FGCP supports widely separated cluster units installed in different physical locations. Distributed clusters can have cluster units in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

Just like any cluster, distributed clusters require heartbeat communication between cluster units. In a distributed cluster this heartbeat communication can take place over the Internet or over other transmission methods including satellite linkups.

Most Data Center Interconnect (DCI) or MPLS-based solutions that support layer 2 extensions between the remote data centers should also support HA heartbeat communication between the FortiGates in the distributed locations. Using VLANs and switches in promiscuous mode to pass all traffic between the locations can also be helpful.

HA heartbeat IP addresses are not configurable so the heartbeat interfaces have to be able to communicate over the same subnet. See [HA heartbeat interface IP addresses on page 1914](#).

Because of the possible distance it may take a relatively long time for heartbeat packets to be transmitted between cluster units. This could lead to a split brain scenario. To avoid a split brain scenario you can increase the heartbeat interval so that the cluster expects extra time between heartbeat packets. A general rule is to configure the failover time to be longer than the max latency. You could also increase the `hb-lost-threshold` to tolerate losing heartbeat packets if the network connection is less reliable.

In addition you could use different link paths for heartbeat packets to optimize HA heartbeat communication. You could also configure QoS on the links used for HA heartbeat traffic to make sure heartbeat communication has the highest priority.

For information about changing the heartbeat interval and other heartbeat related settings, see [Modifying heartbeat timing on page 1916](#).

Clusters of three or four FortiGates

The FGCP supports a cluster of two, three, or four FortiGates. You can add more than two units to a cluster to improve reliability: if two cluster units fail the third will continue to operate and so on. A cluster of three or four units in active-active mode may improve performance since another cluster unit is available for security profile processing. However, active-active FGCP HA results in diminishing performance returns as you add units to the cluster, so the additional performance achieved by adding the third cluster unit may not be worth the cost.

There are no special requirements for clusters of more than two units. Here are a few recommendations though:

- The matching heartbeat interfaces of all of the cluster units must be able to communicate with each other. So each unit's matching heartbeat interface should be connected to the same switch. If the ha1 interface is used for heartbeat communication, then the ha1 interfaces of all of the units in the cluster must be connected together so communication can happen between all of the cluster units over the ha1 interface.
- Redundant heartbeat interfaces are recommended. You can reduce the number of points of failure by connecting each matching set of heartbeat interfaces to a different switch. This is not a requirement; however, and you can connect both heartbeat interfaces of all cluster units to the same switch. However, if that switch fails the cluster will stop forwarding traffic.
- For any cluster, a dedicated switch for each heartbeat interface is recommended because of the large volume of heartbeat traffic and to keep heartbeat traffic off of other networks, but it is not required.
- Full mesh HA can scale to three or four FortiGates. Full mesh HA is not required if you have more than 2 units in a cluster.
- Virtual clustering can only be done with two FortiGates.

Connecting a cluster of three FortiGates

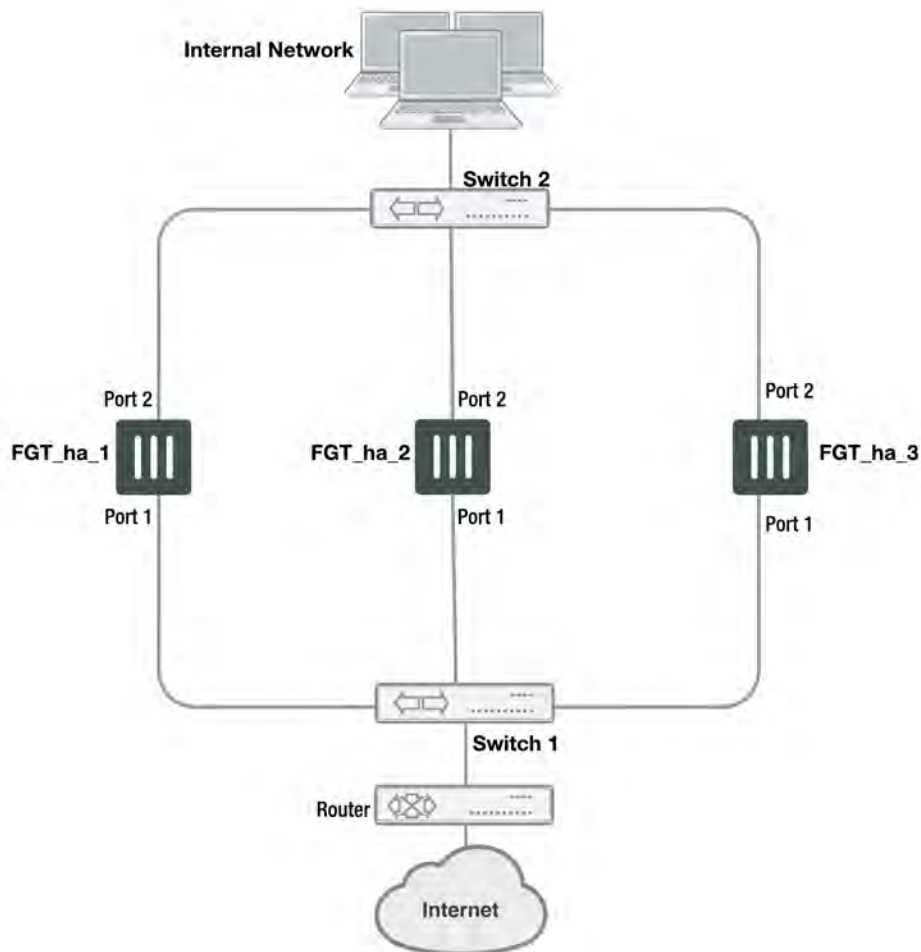

This example shows how to connect a cluster of three FortiGates where:

- Port1 connects the cluster to the Internet
- Port2 connects the cluster to the internal network
- Port3 and Port4 are the heartbeat interfaces

Use the following steps to connect the cluster units to each other and to their networks:

1. Connect the network interfaces:

- Connect the port1 interface of each FortiGate to the same switch (Switch 1) and connect this switch to the Internet.
- Connect the port2 interface of each FortiGate to the same switch (Switch 2) and connect this switch to the internal Network.

Connecting the network interfaces (cluster of three FortiGates)

2. Connect the heartbeat interfaces:

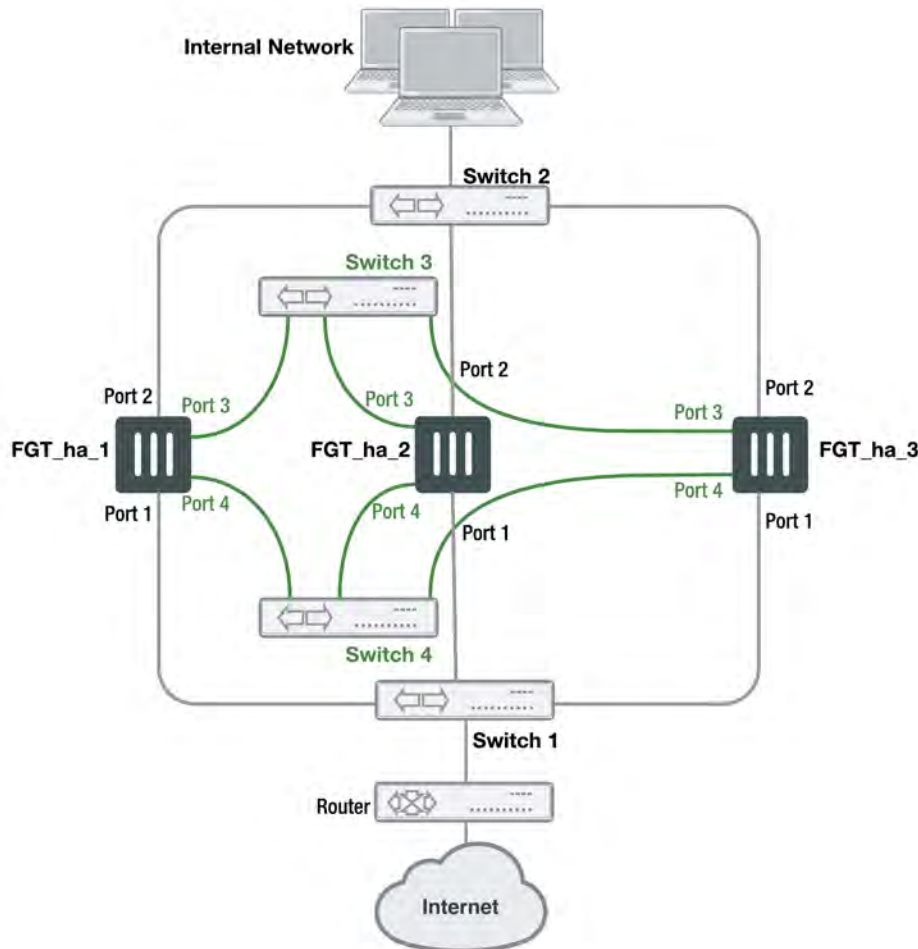

- Connect the port3 interface of each FortiGate to the same switch (Switch 3)
- Connect the port4 interface of each FortiGate to the same switch (Switch 4)

Connecting the heartbeat interfaces (cluster of three FortiGates)

The network and heartbeat connections when combined into one diagram appear like the following:

Network and heartbeat interface connections (cluster of three FortiGates)

Disk storage configuration and HA

If your cluster units include storage disks (for example for storing log messages, WAN optimization data and web caching) all cluster units must have identical storage disk configurations. This means each cluster unit must have same number of disks (including AMC and FortiGate Storage Module (FSM) hard disks) and also means that matching disks in each cluster unit must be the same size, have the same format, and have the same number of partitions.

In most cases the default hard disk configuration of the cluster units will be compatible. However, a hard disk formatted by an older FortiGate firmware version may not be compatible with a hard disk formatted by a more recent firmware version. Problems may also arise if you have used the `execute scsi-dev` command to add or change hard disk protections.

If a cluster unit CLI displays hard disk compatibility messages, you may need to use the `execute scsi-dev delete` command to delete partitions. You can also use the `execute formatlogdisk` command to

reformat disks. In some cases after deleting all partitions and reformatting the disks, you may still see disk incompatibility messages. If this happens, contact Fortinet Customer Support for assistance.

FGCP high availability best practices

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling `session-pickup-delay` to improve performance by reducing the number of sessions that are synchronized. See [Improving session synchronization performance on page 1954](#).
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces. See [Improving session synchronization performance on page 1954](#).
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- Configure at least two heartbeat interfaces and set these interfaces to have different priorities.
- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
 - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See [Enabling or disabling HA heartbeat encryption and authentication on page 1917](#).
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NP4 or NP6 processor to avoid NP4 or NP6-related problems from affecting heartbeat traffic.
- Where possible, the heartbeat interfaces should not be connected to an NP4 or NP6 processor that is also processing network traffic.
- Where possible, each heartbeat interface should be connected to a different NP4 or NP6 processor.
- Any FortiGate interface can be used as a heartbeat interface including 10/100/1000Base-T, SFP, QSFP fiber and copper, and so on. If you set up two or more interfaces as heartbeat interfaces each interface can be a different type and speed.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See [Remote link failover \(remote IP monitoring\) on page 1943](#).

FGCP HA terminology

The following HA-specific terms are used in this document.

Cluster

A group of FortiGate devices that act as a single virtual FortiGate to maintain connectivity even if one of the FortiGate devices in the cluster fails.

Cluster unit

A FortiGate operating in a FortiGate HA cluster.

Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

Failover

A FortiGate taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

Failure

A hardware or software problem that causes a FortiGate or a monitored interface to stop processing network traffic.

FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGate devices in a cluster communicate to keep the cluster operating.

Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

Heartbeat device

An Ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGates. Hello state may appear in HA log messages.

High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGates in the cluster share session and configuration information.

Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see [Link failover \(port monitoring or interface monitoring\)](#) on page 1936.

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique similar to unicast load balancing. The primary unit interfaces are assigned virtual MAC addresses which are associated on the network with the cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule. Communication between the cluster units uses the actual cluster unit MAC addresses.

Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up.

Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

State synchronization

The part of the FGCP that maintains connections after failover.

Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGates operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

HA GUI options

Go to **System > HA** to change HA options. You can set the following options to put a FortiGate into HA mode. You can also change any of these options while the cluster is operating.

You can configure HA options for a FortiGate with virtual domains (VDOMs) enabled by logging into the GUI as the global admin administrator and going to **System > HA**.

If already operating in HA mode, go to **System > HA** to display the cluster members list. You can then edit the primary unit to change HA settings.

Go to **System > HA > View HA Statistics** to view statistics about cluster operation.

Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see [Virtual clusters on page 1850](#).

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

Mode

Select an HA mode for the cluster or return the FortiGate in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select **Standalone** (to disable HA), **Active-Passive**, or **Active-Active**.

If virtual domains are enabled you can select **Active-Passive** or **Standalone**.

Device Priority

Optionally set the device priority of the cluster FortiGate. Each FortiGate in a cluster can have a different device priority. During HA negotiation, the FortiGate with the highest device priority usually becomes the primary unit.

In a virtual cluster configuration, each cluster FortiGate can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate with the highest device priority in a virtual cluster becomes the primary FortiGate for that virtual cluster.

Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster.

Synchronize Management VDOM

This options appears if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can disable this option to prevent the management VDOM configuration from being synchronized between cluster units in the virtual cluster. This allows you to add an interface to the VDOM in each cluster unit and then to give the Interface a different IP address in each cluster unit, allowing you to manage each cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
    set standalone-mgmt-vdom enable
end
```

Group name

Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

Password

Enter a password to identify the cluster. The password must be the same for all cluster FortiGates before the cluster FortiGates can form a cluster.

Two clusters on the same network must have different passwords.

The password is synchronized to all cluster units in an operating cluster. If you change the password of one cluster unit the change is synchronized to all cluster units.

Session pickup

Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit.

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. See [Session failover \(session-pickup\) on page 1953](#).

Monitor interfaces

Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See [Link failover \(port monitoring or interface monitoring\) on page 1936](#).

If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate that still has a connection to the network. This other cluster FortiGate becomes the new primary unit.

Interface monitoring (also called port monitoring) is disabled by default. Leave interface monitoring disabled until the cluster is operating and then only enable interface monitoring for connected interfaces.

You can monitor up to 64 interfaces.

Heartbeat interfaces

Enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The GUI lists interfaces in alphanumeric order:

- port1
- port2 through 9
- port10

Hash map order sorts interfaces in the following order:

- port1
- port10
- port2 through port9

The default heartbeat interface configuration is different for each FortiGate model. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0.

You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See [HA heartbeat and communication between cluster units on page 1911](#).

You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.

Management Interface Reservation

You can provide direct management access to individual cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. You can also specify static routing settings for this interface. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. See [Managing individual cluster units using a reserved out-of-band management interface on page 1875](#).

VDOM partitioning

If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1.

Secondary Cluster Settings

If you are configuring virtual clustering you can set the device priority and configure interface monitoring for the secondary virtual cluster.

FGCP configuration examples and troubleshooting

This chapter contains general procedures and descriptions as well as detailed configuration examples that describe how to configure FortiGate HA clusters.

About the examples in this chapter

The procedures in this chapter describe some of many possible sequences of steps for configuring HA clustering. As you become more experienced with FortiOS HA you may choose to use a different sequence of configuration steps.

For simplicity, many of these procedures assume that you are starting with new FortiGates set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

How to set up FGCP clustering (recommended steps)

This example describes how to enhance the reliability of a network protected by a FortiGate unit by adding a second FortiGate unit and setting up a FortiGate Clustering Protocol (FGCP) High Availability cluster.

The FortiGate already on the network will be configured to become the primary unit by:

- Licensing it (if required)
- Enabling HA

- Increasing its device priority
- Enabling override

The new FortiGate will be prepared by:

- Setting it to factory defaults to wipe any configuration changes
- Licensing it (if required)
- Enabling HA without changing the device priority and override
- Connecting it to the FortiGate already on the network.

The new FortiGate becomes the backup unit and its configuration is overwritten by the primary unit.

Before you start, the FortiGates should be running the same FortiOS firmware version and interfaces should not be configured to get their addresses from DHCP or PPPoE. Also, you cannot use a switch port as an HA heartbeat interface. If necessary, convert the switch port to individual interfaces.

1. Configuring the primary FortiGate

Connect to the primary FortiGate and locate the System Information Dashboard widget. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**. Change the unit's **Host name** to identify it as the primary FortiGate.

Host name External-Primary

You can also enter this CLI command:

```
config system global
    set hostname External-Primary
end
```

Register and apply licenses to the primary FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support**, **IPS**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, **FortiClient**, **FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

```
config system ha
    set mode a-p
    set group-id 25
    set group-name External-HA-Cluster
    set password
    set priority 250
    set override enable
    set hbdev port3 200 port4 100
end
```

Enter this CLI command to set the HA mode to active-passive, set a group id, group name and password, increase the device priority to a higher value (for example, 250) and enable override.

Enabling override and increasing the device priority means this unit should always become the primary unit.

This command also selects port3 and port4 to be the heartbeat interfaces and sets their priorities to 200 and 100 respectively. Its a best practice to set different priorities for the heartbeat interfaces (but not a requirement).

If you have more than one cluster on the same network, each cluster should have a different group id. Changing the group id changes the cluster interface virtual MAC addresses. If your group id setting causes MAC address conflict you can select a different group id.

You can also use the GUI (**System > HA**) to configure most of these settings.

Mode: Active-Passive

Device priority: 250

Cluster Settings

Group name: External-HA-Cluster

Password: Change

Session pickup: ☐

Monitor interfaces: +

Heartbeat interfaces: port3, port4

Heartbeat Interface Priority

Interface	Priority
port3	200
port4	100

Override and the group id can only be configured from the CLI.

```
config system ha
    set group-id 25
    set override enable
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as FGCP negotiation takes place and the MAC addresses of the FortiGate interfaces are changed to HA virtual MAC addresses. These virtual MAC addresses are used for failover. The actual virtual MAC address assigned to each FortiGate interface depends on the HA group ID. Since this example does not involve changing the HA group ID, the FortiGate unit's interfaces will have the following MAC addresses: 00:09:0f:09:00:00, 00:09:0f:09:00:01, 00:09:0f:09:00:02 and so on.

If these steps don't start HA mode, make sure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all ARP table entries). You can usually delete the ARP table from a command prompt using a command similar to `arp -d`. To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) command to view the virtual MAC address of any FortiGate unit interface. Depending on the FortiGate model, the output from this command could include lines similar to the following:

```
Current_HWaddr: 00:09:0f:09:00:00
Permanent_HWaddr 02:09:0f:78:18:c9
```

2. Configuring the backup FortiGate

Enter this command to reset the new FortiGate that will become the backup FortiGate to factory default settings.

```
execute factoryreset
```

You can skip this step if the new FortiGate is fresh from the factory. But if its configuration has been changed at all it is recommended to set it back to factory defaults to reduce the chance of synchronization problems.

If required, change the firmware running on the new FortiGate to be the same version as is running on the primary unit.

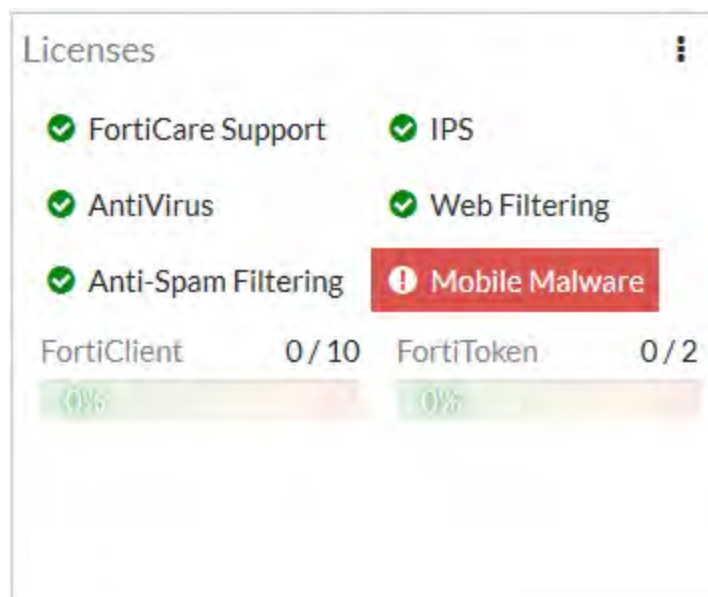

Register and apply licenses to the new FortiGate unit before adding it to the HA cluster. This includes licensing for **FortiCare Support**, **IPS**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, **FortiClient**, **FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

Click on the System Information dashboard widget and select **Configure settings in System > Settings**. Change the FortiGate's **Host name** to identify it as the backup FortiGate.

You can also enter this CLI command:

```
config system global
  set hostname External-Backup
end
```

Host name

Duplicate the primary unit HA settings, except set the **Device Priority** to a lower value (for example, 50) and do not enable override.

If these steps don't start HA mode, make sure that none of the FortiGate's interfaces use DHCP or PPPoE addressing,

```
config system ha
    set mode a-p
    set group-id 25
    set group-name External-HA-Cluster
    set password
    set priority 50
    set hbdev port3 200 port4 100
end
```

3. Connecting the cluster

Connect the HA cluster as shown in the network diagram. Making these connections will disrupt network traffic as you disconnect and re-connect cables.

If possible, make direct Ethernet connections between the heartbeat interfaces of the two FortiGate units.

This example uses two port3 and port4, but you can use any interfaces for HA heartbeat interfaces. A best practice is to use interfaces that do not process traffic, but this is not a requirement.

Switches must be used between the cluster and the Internet and between the cluster and the internal networks as shown in the network diagram. You can use any good quality switches to make these connections. You can also use one switch for all of these connections as long as you configure the switch to separate traffic from the different networks.

When connected, the primary and backup FortiGates find each other and negotiate to form an HA cluster. The Primary unit synchronizes its configuration with the backup FortiGate. Forming the cluster happens automatically with minimal or no disruption to network traffic.

4. Checking cluster operation and disabling override

Check the cluster synchronization status to make sure the primary and backup units have the same configuration. Log into the primary unit CLI and enter this command:

```
diagnose sys ha checksum cluster
```

The command output lists all cluster members' configuration checksums. If both cluster units have identical checksums you can be sure that their configurations are synchronized. If the checksums are different, wait a short while and enter the command again. Repeat until the checksums are identical. It may take a while for some parts of the configuration to be synchronized. If the checksums never become identical visit the [Fortinet Support](#) website to find help with troubleshooting the problem.

The HA Status Dashboard widget also shows if the cluster units are synchronized. Mouse over each FortiGate in the cluster to verify that they both have the same checksum.

When the checksums are identical, disable override on the primary unit (recommended).

```
config system ha
  set override disable
end
```

The HA cluster dynamically responds to network conditions. If you keep override enabled, the same FortiGate will always be the primary FortiGate. Because of this, however, the cluster may negotiate more often potentially increasing traffic disruptions.

If you disable override it is more likely that the new FortiGate unit could become the primary unit. Disabling override is recommended unless its important that the same FortiGate remains the primary unit.

From the **HA Status** widget, select **Configure Settings in System > HA** (or go to **System > HA**) to view the cluster status.

Synchronized	Priority	Hostname	Serial No.	Role	Uptime	Sessions	Throughput
✓	250	External-Primary	FGT6HD3916800525	Master	42d 5h 54m 2s	167	258 bps
✗	50	External-Backup	FGT6HD3916801195	Slave	2h 57m 18s	45	129 bps

From the **HA Status** widget you can also select **Show HA Historical Events** to see the most recent HA system status messages.

HA Historical Events		
#	Date/Time	Event
1	10-05 14:41	FGT6HD3916800525 is elected as the cluster master of 2 members
2	10-05 14:41	new member 'FGT6HD3916801195' joins the cluster
3	10-05 14:41	hbdev port4 link status changed: 0->1
4	10-05 14:41	port port4 link status changed: 0->1
5	10-05 14:41	hbdev port4 link status changed: 1->0
6	10-05 14:41	port port4 link status changed: 1->0
7	10-05 14:41	hbdev port4 link status changed: 0->1
8	10-05 14:41	hbdev port3 link status changed: 0->1
9	10-05 14:41	port port4 link status changed: 0->1
10	10-05 14:41	port port3 link status changed: 0->1
11	10-05 14:40	hbdev port4 link status changed: 1->0
12	10-05 14:40	hbdev port3 link status changed: 1->0
13	10-05 14:40	port port4 link status changed: 1->0

5. Results

Normally, traffic should now be flowing through the primary FortiGate. If the primary FortiGate is unavailable traffic fails over to the backup FortiGate. Failover also causes the primary and backup FortiGates to reverse roles, even when both FortiGates are available again.

To test this, ping the IP address 8.8.8.8 using a PC on the internal network. After a moment, power off the primary FortiGate.

If you are using port monitoring, you can also unplug the primary FortiGate's Internet-facing interface to test failover.

You will see a momentary pause in the ping results, until traffic diverts to the backup FortiGate, allowing the ping traffic to continue.

```

Setting up two new FortiGates as an FGCP cluster

This section describes a simple HA network topology that includes an HA cluster of two FortiGates in NAT mode installed between an internal network and the Internet. The example uses a generic FortiGate with four interfaces

named port1, port2, port3 and port4.

Example NAT mode HA network topology

The figure below shows a typical FortiGate HA cluster consisting of two FortiGates (FGT_ha_1 and FGT_ha_2) connected to the same internal (port2) and external (port1) networks.

Example NAT mode HA network topology

Port3 and port4 are used as the heartbeat interfaces. Because the cluster consists of two FortiGates, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular Ethernet cables.

General configuration steps

The section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.

- Optionally change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
 3. Confirm that the cluster units are operating as a cluster and add basic configuration settings to the cluster.
 - View cluster status from the GUI or CLI.
 - Add a password for the admin administrative account.
 - Change the IP addresses and netmasks of the internal and external interfaces.
 - Add a default route.

Configuring a NAT mode active-passive cluster of two FortiGates - GUI

Use the following procedures to configure two FortiGates for NAT HA operation using the GUI. These procedures assume you are starting with two FortiGates with factory default settings.

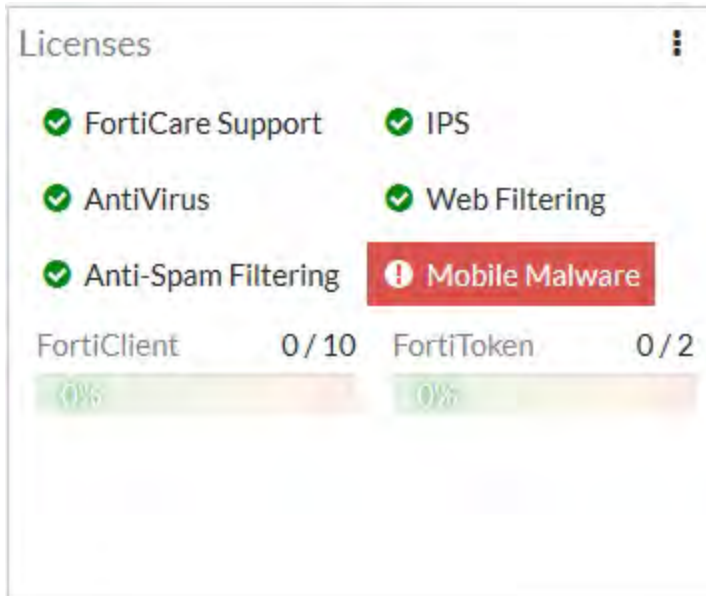

Give each cluster unit a unique host name to make the individual units easier to identify when they are part of a functioning cluster. The default host name is the FortiGate serial number. You may want to change this host name to something more meaningful for your network.

To configure the first FortiGate (host name FGT_ha_1)

1. Register and apply licenses to the FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Passive
Group name	example1.com
Password	HA_pass_1

This is the minimum recommended configuration for an active-passive HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each unit in the cluster.

6. Select **OK**.
The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:
 - port1 interface virtual MAC: 00-09-0f-09-00-00
 - port2 interface virtual MAC: 00-09-0f-09-00-01
 - port3 interface virtual MAC: 00-09-0f-09-00-02
 - port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp

table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HWaddr: 00:09:0f:09:00:00
Permanent_HWaddr 02:09:0f:78:18:c9
.
.
.
```

10. Power off the first FortiGate (FGT_ha_1).

Note the details and format of the output of the `get hardware nic` command are specific to the interface hardware. Different FortiGate models and even different interfaces in the same FortiGate may have different output.

To configure the second FortiGate (host name FGT_ha_2)

1. Register and apply licenses to the FortiGate before configuring it for HA operation.
2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_2
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Passive
Group Name	example1.com
Password	HA_pass_1

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the second FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the HA Status dashboard widget and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate. You could have performed the following configuration steps separately on each FortiGate before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address <https://192.168.1.99> (remember to include the "s" in https://). The FortiGate Login is displayed.
2. Type `admin` in the **Name** field and select Login. The FortiGate dashboard is displayed.

The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
3. Go to **System > HA** to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster to connect to its network. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit `admin` and select **Change Password**.

4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Interfaces**.
7. Edit the **port2** interface and change **IP/Netmask** to 10.11.101.100/24.
8. Select **OK**.

After changing the IP address of the port1 interface you may have to change the IP address of your management computer and then reconnect to the port1 interface using the 172.20.120.141 IP address.

9. Edit the **port1** interface and change **IP/Netmask** to 172.20.120.141/24.
10. Select **OK**.
11. Go to **Network > Static Routes**.
12. Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port1
Distance	10

13. Select **OK**.

Configuring a NAT mode active-passive cluster of two FortiGates - CLI

Use the following procedures to configure two FortiGates for NAT HA operation using the FortiGate CLI. These procedures assume you are starting with two FortiGates with factory default settings.

To configure the first FortiGate (host name FGT_ha_1)

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal (or any terminal emulation program), enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.

The FortiGate CLI login prompt appears.

If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate.
9. Change the host name for this FortiGate.

```
config system global
  set hostname FGT_ha_1
end
```

10. Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example1.com
  set password HA_pass_1
end
```

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port2 interface virtual MAC: 00-09-0f-09-00-01
- port3 interface virtual MAC: 00-09-0f-09-00-02
- port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr 02:09:0f:78:18:c9
.
.
.
```

10. Display the HA configuration (optional).

```
get system ha
  group-id : 0
  group-name : example1.com
  mode : a-p
  password : *
```

```

hbdev : "port3" 50 "port4" 50

```

11. Power off the FortiGate.

To configure the second FortiGate (host name FGT_ha_2)

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None

Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
The FortiGate CLI login prompt appears.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate.
9. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
FortiToken licenses can be added at any time because they are synchronized to all cluster members.
10. Change the host name for this FortiGate.

```
config system global
  set hostname FGT_ha_2
end
```

11. Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example1.com
  set password HA_pass_1
end
```

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

12. Display the HA configuration (optional).

```
get system ha
group-id : 0
group-name : example1.com
mode : a-p
password : *
hbdev : "port3" 50 "port4" 50
session-sync-dev :
route-ttl : 10
route-wait : 0
route-hold : 10
sync-config : enable
encryption : disable
authentication : disable
hb-interval : 2
hb-lost-threshold : 20
hello-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
```

```

uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
slave-switch-standby: disable
minimum-worker-threshold: 1
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"

```

13. Power off the FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.
 - Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
 - Enter the command `get system status`.
 - If the command output includes `Current HA mode: a-p, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step ["Setting up two new FortiGates as an FGCP cluster" on page 1778](#).
 - If the command output includes `Current HA mode: a-p, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

3. Check the cluster synchronization status to make sure the primary and backup units have the same configuration. Log into the primary unit CLI and enter this command:

```
diagnose sys ha checksum show
```

The CLI lists all members' checksums. If both cluster units have identical checksums you can be sure that their configurations are synchronized. If the checksums are different wait a short while and enter the command again. Repeat until the checksums are identical. It may take a while for some parts of the configuration to be synchronized. If the checksums never become identical visit the [Fortinet Support](#) website to find help troubleshooting the problem.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to add some basic settings to the cluster so that it can connect to the network.

1. Log into the primary unit CLI.
2. Add a password for the admin administrative account.

```
config system admin
edit admin
set password <password_str>
end
```

3. Configure the port1 and port2 interfaces.

```
config system interface
edit port1
set ip 172.20.120.141/24
next
edit port2
set ip 10.11.101.100/24
end
```

4. Add a default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device port1
  end
```

Adding a new FortiGate to an operating cluster

This procedure describes how to add a new FortiGate to a functioning cluster. Adding a new unit to a cluster does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the new cluster unit.

You can use this procedure to add as many units as required to the cluster.

To add a new unit to a functioning cluster

1. Install the same firmware build on the new cluster unit as is running on the cluster.
2. Register and apply licenses to the primary FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

3. Configure the new cluster unit for HA operation with the same HA configuration as the other units in the cluster.
4. If the cluster is running in transparent mode, change the operating mode of the new cluster unit to transparent mode.
5. Power off the new cluster unit.
6. Connect the new cluster unit to the cluster.
7. For example, see [How to set up FGCP clustering \(recommended steps\) on page 1771](#).
8. Power on the new cluster unit.

When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the new unit configuration with the configuration of the primary unit.

You can add a new unit to a functioning cluster at any time. For best results the new cluster unit should:

- Have the same hardware version as the cluster units.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or transparent) as the cluster.
- Be operating in single VDOM mode.

Active-active HA cluster in transparent mode

This section describes a simple HA network topology that includes an HA cluster of two generic FortiGate installed between an internal network and the Internet and running in transparent mode.

Example transparent mode HA network topology

The figure below shows a transparent mode FortiGate HA cluster consisting of two FortiGate (FGT_ha_1 and FGT_ha_2) installed between the Internet and internal network. The topology includes a router that performs NAT between the internal network and the Internet. The cluster management IP address is 10.11.101.100.

Transparent mode HA network topology

Port3 and port4 are used as the heartbeat interfaces. Because the cluster consists of two FortiGate, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular Ethernet cables.

General configuration steps

This section includes GUI and CLI procedures. These procedures assume that the FortiGate are running the same FortiOS firmware build and are set to the factory default configuration.

In this example, the configuration steps are identical to the NAT mode configuration steps until the cluster is operating. When the cluster is operating, you can switch to transparent mode and add basic configuration settings to cluster.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.
 - Optionally change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster.
4. Switch the cluster to transparent mode and add basic configuration settings to the cluster.
 - Switch to transparent mode, add the management IP address and a default route.
 - Add a password for the admin administrative account.
 - View cluster status from the GUI or CLI.

Configuring a transparent mode active-active cluster of two FortiGates - GUI

Use the following procedures to configure the FortiGates for HA operation using the FortiGate GUI. These procedures assume you are starting with two FortiGates with factory default settings.

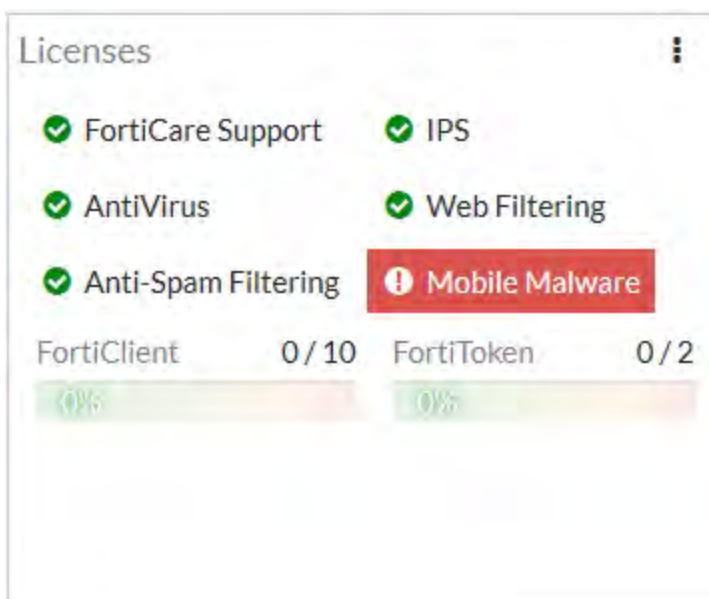

Waiting until you have established the cluster to switch to transparent mode means fewer configuration steps because you can switch the mode of the cluster in one step.

To configure the first FortiGate (host name FGT_ha_1)

1. Register and apply licenses to the FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port2 interface virtual MAC: 00-09-0f-09-00-01
- port3 interface virtual MAC: 00-09-0f-09-00-02
- port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr 02:09:0f:78:18:c9
.
.
.
```

10. Power off the first FortiGate.

To configure the second FortiGate (host name FGT_ha_2)

1. Register and apply licenses to the FortiGate before configuring it for HA operation.

2. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_2
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the second FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To switch the cluster to transparent mode

Switching from NAT to transparent mode involves adding the transparent mode management IP address and default route.

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

1. Start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).
- The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.
 3. Under System Information, beside **Operation Mode** select **Change**.
 4. Set Operation Mode to transparent.
 5. Configure basic transparent mode settings.

Operation Mode	Transparent
Management IP/Mask	10.11.101.100/24
Default Gateway	10.11.101.2

6. Select **Apply**.

The cluster switches to operating in transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate. You could have performed the following configuration steps separately on each FortiGate before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address <https://10.11.101.100> (remember to include the “s” in https://). The FortiGate Login is displayed.
2. Type **admin** in the Name field and select **Login**.
The FortiGate dashboard is displayed.

The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
3. Go to **System > HA** to view the cluster members list.
The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster. Note that the following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.

You added a default gateway when you switched to transparent mode so you don't need to add a default route as part of the basic configuration of the cluster at this point.

Configuring a transparent mode active-active cluster of two FortiGates - CLI

Use the following procedures to configure the FortiGates for transparent mode HA operation using the FortiGate CLI.

To configure each FortiGate for HA operation

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
The FortiGate CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate.
9. Change the host name for this FortiGate. For example:

```
config system global
  set hostname FGT_ha_1
end
```

10. Configure HA settings.

```
config system ha
  set mode a-a
  set group-name example2.com
  set password HA_pass_2
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port2 interface virtual MAC: 00-09-0f-09-00-01
- port3 interface virtual MAC: 00-09-0f-09-00-02
- port4 interface virtual MAC: 00-09-0f-09-00-03

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent_HWaddr):

```
get hardware nic port1
.
.
.
Current_HAaddr      00:09:0f:09:00:00
Permanent_HWaddr    02:09:0f:78:18:c9
.
.
.
```

10. Display the HA configuration (optional).

```
get system ha
  group-id : 0
  group-name : example2.com
  mode : a-a
  password : *
  hbdev : "port3" 50 "port4" 50
  session-sync-dev :
  route-ttl : 10
  route-wait : 0
  route-hold : 10
  sync-config : enable
  encryption : disable
  authentication : disable
  hb-interval : 2
  hb-lost-threshold : 20
  hello-holddown : 20
  arps : 5
  arps-interval : 8
  session-pickup : disable
  update-all-session-timer: disable
```

```

session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
slave-switch-standby: disable
minimum-worker-threshold: 1
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"

```

11. Power off the FortiGate.

To configure the second FortiGate (host name FGT_ha_2)

1. Power on the FortiGate.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.

The FortiGate CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate.
9. Change the host name for this FortiGate.

```
config system global
```

```

    set hostname FGT_ha_2
end

```

10. Configure HA settings.

```

config system ha
    set mode a-a
    set group-name example2.com
    set password HA_pass_2
end

```

The FortiGate negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

11. Display the HA configuration (optional).

```

get system ha
group-id : 0
group-name : example2.com
mode : a-a
password : *
hbdev : "port3" 50 "port4" 50
session-sync-dev :
route-ttl : 10
route-wait : 0
route-hold : 10
sync-config : enable
encryption : disable
authentication : disable
hb-interval : 2
hb-lost-threshold : 20
hello-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
schedule : round-robin
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60

```

```
vdom : "root"  
schedule : round-robin
```

12. Power off the FortiGate.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To connect to the cluster CLI and switch the cluster to transparent mode

1. Determine which cluster unit is the primary unit.
 - Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
 - Enter the command `get system status`.
 - If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.
 - If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode.

2. Change to transparent mode.

```
config system settings  
  set opmode transparent  
  set manageip 192.168.20.3/24  
  set gateway 192.168.20.1  
end
```

The cluster switches to transparent Mode, and your administration session is disconnected.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (192.168.20.3).

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step ["Active-active HA cluster in transparent mode" on page 1791](#).
- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGates are not functioning as a cluster. See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
edit admin
set password <psswr>
end
```

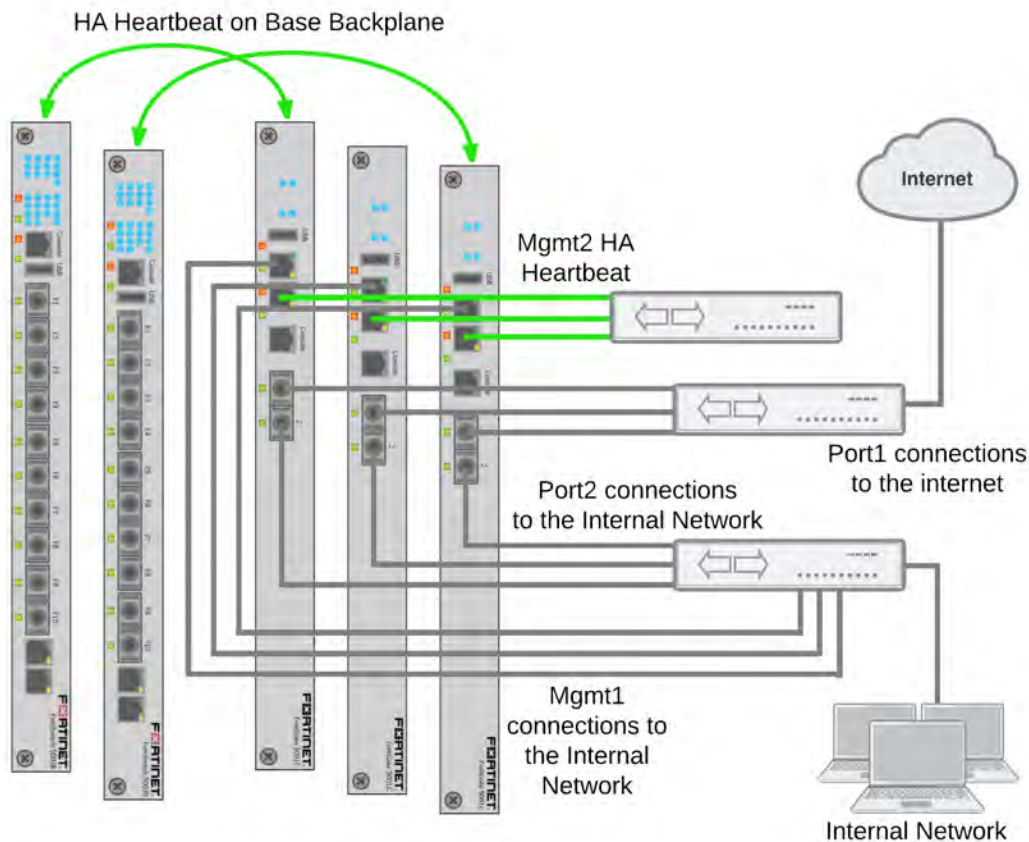

FortiGate-5000 active-active HA cluster with FortiClient licenses

This section describes how to configure an HA cluster of three FortiGate-5001D units that connect an internal network to the Internet. The FortiGate-5001D units each have a FortiClient license installed on them to support FortiClient profiles.

Normally it is recommended that you add FortiClient licenses to the FortiGates before setting up the cluster. This example; however, describes how to apply FortiClient licenses to the FortiGates in an operating cluster.

Example network topology

The following diagram shows an HA cluster consisting of three FortiGate-5001D cluster units (host names slot-3, slot-4, and slot-5) installed in a FortiGate-5000 series chassis with two FortiController-5003B units for heartbeat communication between the cluster units. The cluster applies security features including FortiClient profiles to data traffic passing through it.

The cluster is managed from the internal network using the FortiGate-5001D mgmt1 interfaces configured as HA reserved management interfaces. Using these reserved management interfaces the overall cluster can be managed and cluster units can be managed individually. Individual management access to each cluster unit makes some operations, such as installing FortiClient licenses, easier and also allows you to view status of each cluster unit.

The reserved management interface of each cluster unit has a different IP address and retains its own MAC address. The cluster does not change the reserved management interface MAC address.

Example network topology

By default base1 and base2 are used for heartbeat communication between the FortiGates. To use the base1 and base2 interfaces for the HA heartbeat, the example describes how to display the backplane interfaces on the GUI before turning on HA.

This example also includes using the mgmt2 interface for heartbeat communication for additional heartbeat redundancy.

To connect the cluster

1. Connect the FortiGate-5001D port1 interfaces to a switch and connect that switch to the Internet.
2. Connect the FortiGate-5001D port2 interfaces to a switch and connect that switch to the internal network.
3. Connect the FortiGate-5001D mgmt1 interfaces to a switch that connects to the engineering network.
4. Connect the FortiGate-5001D mgmt2 interfaces to a switch for heartbeat communication between them.

Configuring the FortiGate-5000 active-active cluster - GUI

These procedures assume you are starting with three FortiGate-5001D boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001D boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5001D units

1. From the internal network, log into the GUI of the FortiGate-5001D unit in chassis slot 3 by connecting to the mgmt1 interface.

By default the mgmt1 interface of each FortiGate-5001D unit has the same IP address. To log into each FortiGate-5001D unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

2. Register and apply licenses to the FortiGate before configuring it for HA operation. This includes licensing for **FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs. **FortiToken** licenses can be added at any time because they are synchronized to all cluster members. FortiClient licenses will be added in a following step.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

3. Click on the System Information dashboard widget and select **Configure settings** in **System > Settings**.
4. Enter a new Host Name for this FortiGate, for example:

New Name	5001D-Slot-3
----------	--------------

5. Connect to the CLI and enter the following command to display backplane interfaces on the GUI:

```
config system global
    set show-backplane-intf enable
end
```

6. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.

You can do this from the GUI by going to **Network > Interfaces**, editing each interface and setting **Administrative Status** to **Up**.

You can also do this from the CLI using the following command:

```
config system interface
    edit base1
        set status up
    next
    edit base2
        set status up
end
```

7. Go to **Network > Interfaces** and configure the IP address of the mgmt1 interface.

Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001D should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

After the FortiGate is operating in HA mode the mgmt1 interface will retain its original MAC address instead of being assigned a virtual MAC address.

8. Go to **System > HA** and change the following settings:

Set the **Mode** to **Active-Active**.

Select **Reserve Management Port for Cluster Member** and select **mgmt1**.

Set the group name and password:

Group Name	example3.com
Password	HA_pass_3

Set the Heartbeat interface configuration to use base1, base2 and mgmt2 for heartbeat communication. Set the priority of each heartbeat interface to 50:

Heartbeat Interface		
	Enable	Priority
base1	Select	50
base2	Select	50
mgmt2	Select	50

9. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate-5001D interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- fabric3 interface virtual MAC: 00-09-0f-09-00-04
- fabric4 interface virtual MAC: 00-09-0f-09-00-05
- fabric5 interface virtual MAC: 00-09-0f-09-00-06
- mgmt1 keeps its original MAC address
- mgmt2 interface virtual MAC: 00-09-0f-09-00-08
- port1 interface virtual MAC: 00-09-0f-09-00-09
- port2 interface virtual MAC: 00-09-0f-09-00-0a

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic base1
```

```

.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.

```

9. Repeat these steps for the FortiGate-5001D units in chassis slots 4 and 5, with the following differences.
Set the mgmt1 interface IP address of each FortiGate-5001D unit to a different IP address.

Set the FortiGate-5001D unit in chassis slot 4 host name to:

New Name	5001D-Slot-4
----------	--------------

Set the FortiGate-5001D unit in chassis slot 5 host name to:

New Name	5001D-Slot-5
----------	--------------

As you configure each FortiGate, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the GUI of one of the cluster units to view the status of the cluster. The status displays will show each unit as it is added to the cluster.

1. Log into the primary unit or any cluster unit and view the system dashboard.
The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed) You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
2. Go to **System > HA** to view the cluster members list.
The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster

See [Troubleshooting HA clusters on page 1845](#).

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster

units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster GUI.
You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Interfaces** and edit the **port1** interface. Set this interface IP address to the address required to connect to the interface to the Internet.
7. Edit the port2 interface and set its IP to an IP address for the internal network.

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGates before forming the cluster. However, you can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can log into <https://support.fortinet.com> and add a FortiClient license key to each licensed FortiGate. Then, as long as the cluster can connect to the Internet the license keys are downloaded from the FortiGuard network to all of the FortiGates in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the GUI. Your cluster must be connected to the Internet.

1. Log into the GUI of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside FortiClient select **Enter License**.
3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the following command to add the license key from the CLI:

```
execute FortiClient-NAC update-registration-license <license-number>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Configuring the FortiGate-5000 active-active cluster - CLI

These procedures assume you are starting with three FortiGate-5001D boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001D boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5005FA2 units

1. From the internal network, log into the CLI of the FortiGate-5001D unit in chassis slot 3 by connecting to the mgmt1 interface.

By default the mgmt1 interface of each FortiGate-5001D unit has the same IP address. To log into each FortiGate-5001D unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

You can also use a console connection.

2. Register and apply licenses to the FortiGate.
 3. Change the host name for this FortiGate. For example:
4. Enter the following command to display backplane interfaces on the GUI:

```
config system global
  set hostname 5001D-Slot-3
end
```

```
config system global
  set show-backplane-intf enable
end
```

5. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.

```
config system interface
  edit base1
    set status up
  next
  edit base2
    set status up
end
```

6. Add an IP address to the mgmt1 interface.

```
config system interface
  edit mgmt1
    set ip 172.20.120.110/24
    set allowaccess http https ssl ping
  end
```

Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001D should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

7. Configure HA settings.

```

config system ha
    set mode a-a
    set ha-mgmt-status enable
    set ha-mgmt-interface mgmt1
    set group-name example3.com
    set password HA_pass_3
    set hbdev base1 50 base2 50 mgmt2 50
end

```

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate-5001D interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- fabric3 interface virtual MAC: 00-09-0f-09-00-04
- fabric4 interface virtual MAC: 00-09-0f-09-00-05
- fabric5 interface virtual MAC: 00-09-0f-09-00-06
- mgmt1 keeps its original MAC address
- mgmt2 interface virtual MAC: 00-09-0f-09-00-08
- port1 interface virtual MAC: 00-09-0f-09-00-09
- port2 interface virtual MAC: 00-09-0f-09-00-0a

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```

get hardware nic base1
.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.

```

7. Repeat these steps for the FortiGate-5001D units in chassis slots 4 and 5, with the following differences. Set the mgmt1 interface IP address of each FortiGate-5001D unit to a different IP address.

Set the FortiGate-5001D unit in chassis slot 4 host name to:

```

config system global
    set hostname 5001D-Slot-4
end

```

Set the FortiGate-5001D unit in chassis slot 5 host name to:

```
config system global
  set hostname 5001D-Slot-5
end
```

As you configure each FortiGate, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the CLI of one of the cluster units using its reserved management interface to view the status of the cluster. The status will show each unit as it is added to the cluster.

For example, the following command output shows the status of the cluster when all three cluster units have been added:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
Slave : 5001d-slot4      , FG-5KD3914800284, operating cluster index = 2
Master: 5001d-slot5      , FG-5KD3914800353, operating cluster index = 0
Slave : 5001d-slot3      , FG-5KD3914800344, operating cluster index = 1
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster

See [Troubleshooting HA clusters on page 1845](#).

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster CLI.

You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.

2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

3. Set the port1 interface IP address to the address required to connect to the interface to the Internet.

```
config system interface
  edit port1
    set ip 10.10.10.10/24
  end
```

4. Set the port2 interface IP address to the address required to connect to the interface to the internal network.

```
config system interface
  edit port2
    set ip 172.20.120.12/24
  end
```

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGates before forming the cluster. However, you can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can log into <https://support.fortinet.com> and add a FortiClient license key to each licensed FortiGate. Then, as long as the cluster can connect to the Internet the license keys are downloaded from the FortiGuard network to all of the FortiGates in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the CLI. Your cluster must be connected to the Internet.

1. Log into the CLI of each cluster unit using its reserved management interface IP address.
2. Enter the following command to the unit's serial number:

```
get system status
```

3. Enter the following command to add the license key for that serial number:

```
execute FortiClient-NAC update-registration-license <license-key>
```

4. Confirm that the license has been installed and the correct number of FortiClients are licensed.

```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
  NAC: 114
  WANOPT: 0
  Test: 0
Other connections:
  IPsec: 0
  SSLVPN: 0
```

5. Repeat for all of the cluster units.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Converting a standalone FortiGate to a cluster

In this example, a backup FortiGate will be installed and connected to a FortiGate that has previously been installed to provide redundancy if the primary FortiGate fails.

In this recipe, a backup FortiGate unit is installed and connected to a previously installed FortiGate to form a high availability (HA) cluster that improves network reliability.

Before you begin, the FortiGates should be running the same FortiOS firmware version and interfaces should not be configured to get their addresses from DHCP or PPPoE. Also, you cannot use a switch port as an HA heartbeat interface. If necessary, convert the switch port to individual interfaces.

This example uses the FortiGate Clustering Protocol (FGCP) for HA. The previously installed FortiGate will continue to operate as the primary unit and the new FortiGate will operate as the backup FortiGate.

1. Setting up registration and licensing

Make sure both FortiGates are running the same FortiOS firmware version. Register and apply licenses to the new FortiGate unit before adding it to the HA cluster. This includes licensing for **FortiCare Support, IPS, AntiVirus, Web Filtering, Mobile Malware, FortiClient, FortiCloud**, and additional **virtual domains** (VDOMs). All FortiGates in the cluster must have the same level of licensing for FortiGuard, FortiCloud, FortiClient, and VDOMs.

FortiToken licenses can be added at any time because they are synchronized to all cluster members.

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed, third-party certificates are synchronized to the backup FortiGate.

2. Configuring the primary FortiGate for HA

On the primary FortiGate, go to **System > Settings** and change the **Host name** to identify this as the primary FortiGate in the HA cluster.

Go to **System > HA** and set the **Mode** to **Active-Passive**. Set the **Device priority** to a higher value than the default (in the example, 250) to make sure this FortiGate will always be the primary FortiGate. Also, set a **Group name** and **Password**.

Make sure that two **Heartbeat interfaces** (in the example, port3 and port4) are selected and the **Heartbeat Interface Priority** for each is set to 50.

Since the backup FortiGate is not available, when you save the HA configuration, the primary FortiGate will form a cluster of one FortiGate but will keep operating normally. If these steps don't start HA mode, make sure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

Mode: Active-Passive

Device priority: 250

Cluster Settings

Group name: External-HA-cluster

Password: [masked]

Session pickup: [disabled]

Monitor interfaces: +

Heartbeat interfaces: port3, port4

Heartbeat Interface Priority

Interface	Priority
port3	50
port4	50

If there are other FortiOS HA clusters on your network, you may need to change the cluster group ID using this CLI command.

```
config system ha
  set group-id 25
end
```

3. Connecting the backup FortiGate

Connect the backup FortiGate to the primary FortiGate and the network, as shown in the network diagram at the top of the recipe. Making these network connections will disrupt traffic so you should do this when the network is not processing much traffic.

If possible, make direct Ethernet connections between the heartbeat interfaces of the two FortiGate units. This example uses two FortiGate-600Ds and the default heartbeat interfaces are used (port3 and port4). You can use any interfaces for HA heartbeat interfaces. A best practice is to use interfaces that do not process traffic, but this is not a requirement.

Switches must be used between the cluster and the Internet, and between the cluster and the internal networks, as shown in the network diagram. You can use any good quality switches to make these connections. You can also use one switch for all of these connections, as long as you configure the switch to separate traffic from the different networks.

4. Configuring the backup FortiGate for HA

Connect to the backup FortiGate GUI and go to **System > Settings** and change the **Host name** to identify this as the backup FortiGate.

Host name

Go to **System > HA** and duplicate the HA configuration of the primary FortiGate (except for the **Device priority**): set **Mode** to **Active-Passive**, and set the **Device Priority** to a lower value than the default to make sure this FortiGate will always be the backup FortiGate. Also, set the same **Group name** and **Password** as the primary FortiGate.

Make sure that the same two **Heartbeat interfaces** (port3 and port4) are selected and the **Heartbeat Interface Priority** for each is set to 50.

Mode Active-Passive

Device priority 50

Cluster Settings

Group name External-HA-cluster

Password ••••

Session pickup ☐

Monitor interfaces +

Heartbeat interfaces

	port3	
	port4	
		+

Heartbeat Interface Priority i

port3		50
port4		50

If you changed the cluster group id of the primary FortiGate, change the cluster group ID for the backup FortiGate to match, using this CLI command.

```
config system ha
  set group-id 25
end
```

When you save the HA configuration of the backup FortiGate, if the heartbeat interfaces are connected, the FortiGates will find each other and form an HA cluster. Network traffic may be disrupted for a few seconds while the cluster is negotiating. If these steps don't start HA mode, make sure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

5. Viewing the status of the HA cluster

Connect to the GUI of the primary FortiGate. The **HA Status** widget shows the cluster mode (**Mode**) and group name (**Group**). It also shows the host name of the primary FortiGate (**Master**), which you can hover over to verify that the cluster is synchronized and operating normally. You can click on the widget to change the HA configuration or view a list of recently recorded cluster events, such as members joining or leaving the cluster.

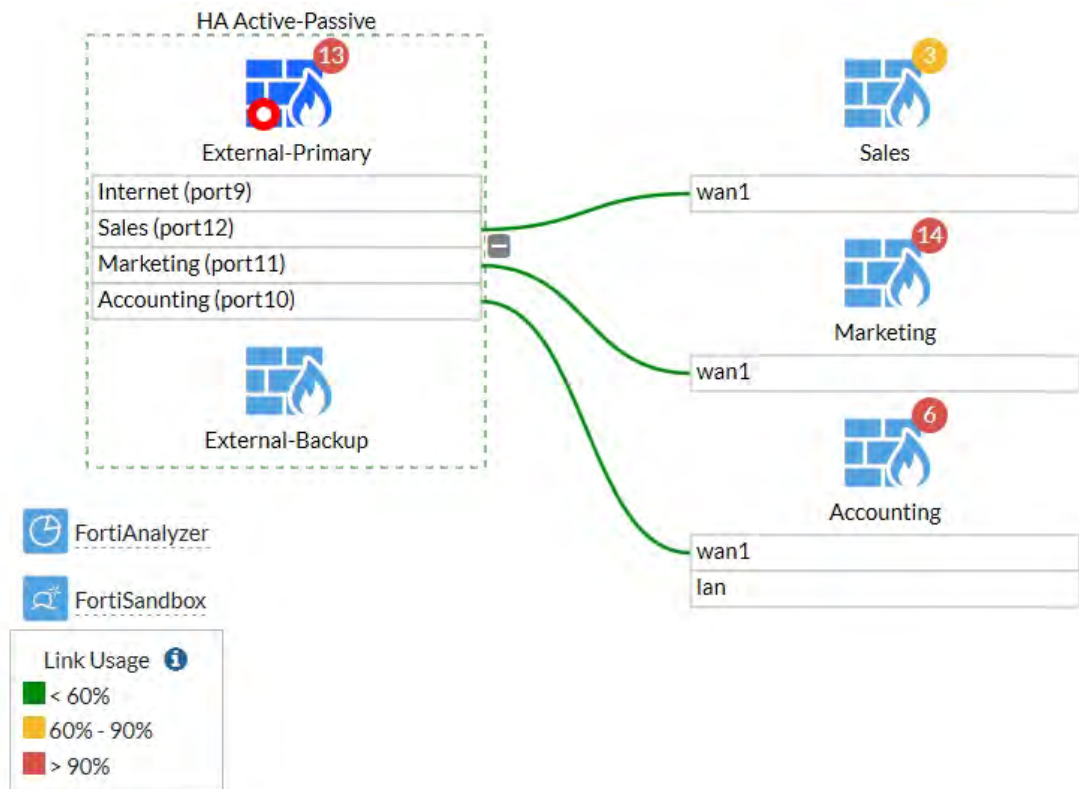

HA Status

Mode	Active-Passive
Group	External-HA-Cluster
Master	✓ External-Primary
Slave	✓ External-Backup
Uptime	00:00:43:06
State Changed	00:00:02:07

Click on the **HA Status** widget and select **Configure settings in System > HA** (or go to **System > HA**) to view the cluster status.

Synchronized	Priority	Hostname	Serial No.	Role	Uptime	Sessions	Throughput
							
✓	250	External-Primary	FGT6HD3916800525	Master	42d 5h 54m 2s	167	258 bps
							
✗	50	External-Backup	FGT6HD3916801195	Slave	2h 57m 18s	45	129 bps

If the cluster is part of a Security Fabric, the FortiView Physical and Logical Topology views show information about the cluster status.

6. Results

Traffic is now passing through the primary FortiGate. However, if the primary FortiGate becomes unavailable, traffic should fail over and the backup FortiGate will process traffic.

A failover also causes the primary and backup FortiGate to reverse roles, even when both FortiGates are available again.

To test HA failover, from a PC on the internal network, ping an IP address on the Internet (in the example, 8.8.8.8). After a moment, power off the primary FortiGate. If you are using port monitoring, you can also unplug the primary FortiGate's Internet-facing interface to test failover. You will see a momentary pause in the ping results, until traffic fails over to the backup FortiGate, allowing the ping traffic to continue.

7. (Optional) Upgrading the firmware for the HA cluster

Upgrading the firmware on the primary FortiGate automatically upgrades the firmware on the backup FortiGate. Both FortiGates are updated with minimal traffic disruption. For information about accessing firmware images, see [Verifying and updating the FortiGate unit's firmware](#).

Always review the Release Notes and [Supported Upgrade Paths](#) before installing new firmware.

Click the **System Information** widget and select **Update firmware in System > Firmware**. Back up the configuration and update the firmware from FortiGuard or by uploading a firmware image file. The firmware installs onto both the primary and backup FortiGates.

After the upgrade is complete, verify that the **System Information** widget shows the new firmware version.

System Information		
Hostname	External-Primary	
Serial Number	FGT6HD3916800525	
Firmware	v5.6.0 build1449 (GA)	
Mode	NAT (Flow-based)	
System Time	2017/05/12 13:22:14	
Uptime	42:06:07:39	
WAN IP	209.87.240.98	
	Kanata, Ontario	

Replacing a failed cluster unit

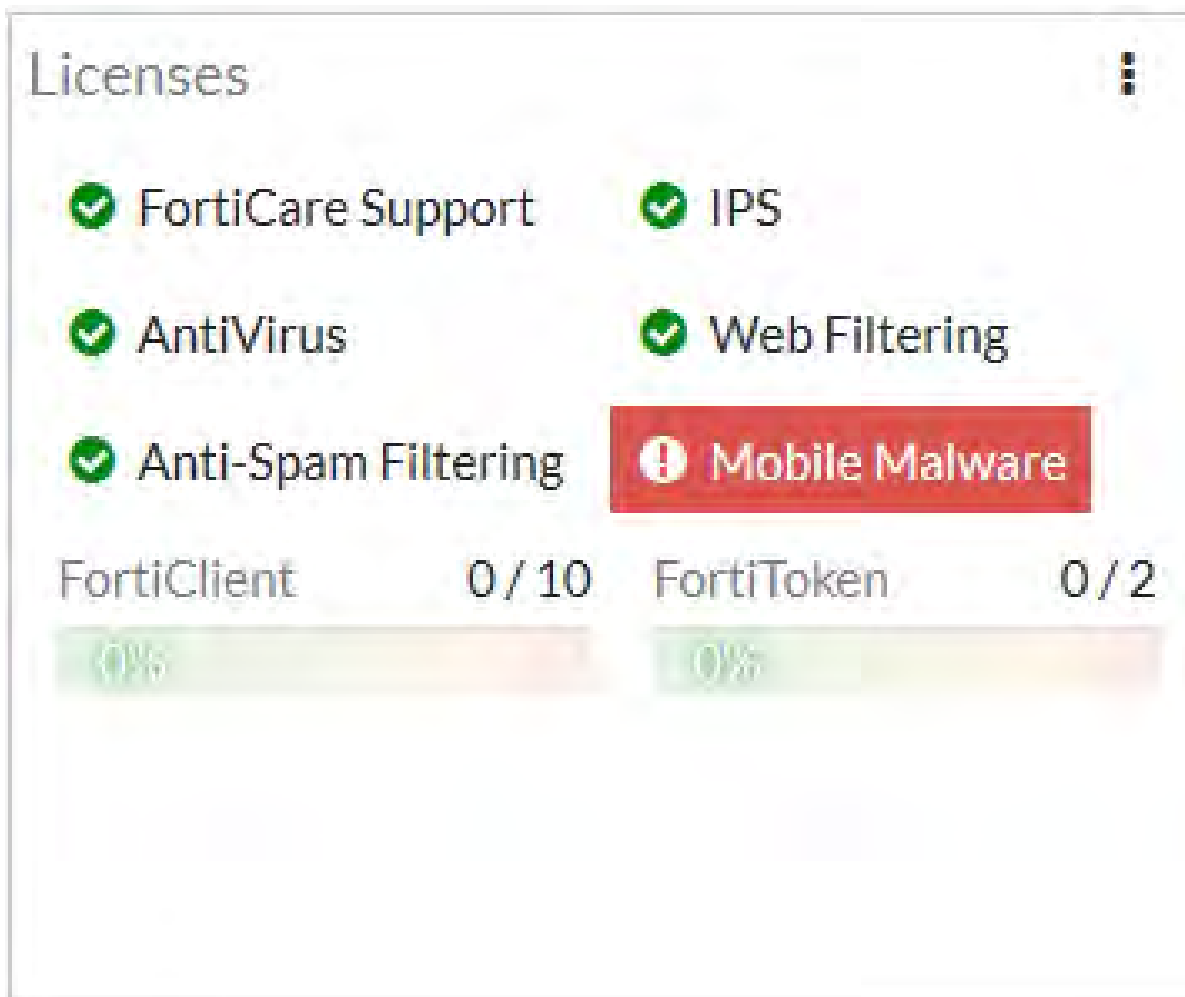

This procedure describes how to remove a failed cluster unit from a cluster and add a new one to replace it. You can also use this procedure to remove a failed unit from a cluster, repair it and add it back to the cluster.

Replacing a failed does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the replacement unit.

You can use this procedure to replace more than one cluster unit.

To replace a failed cluster unit

1. Disconnect the failed unit from the cluster and the network.
If you maintain other connections between the network and the still functioning cluster unit or units and between remaining cluster units network traffic will continue to be processed.
2. Repair the failed cluster unit, or obtain a replacement unit with the exact same hardware configuration as the failed cluster unit.
3. Install the same firmware build on the repaired or replacement unit as is running on the cluster.
4. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.

5. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
We recommend that you add FortiToken licenses and FortiTokens to the primary unit after the cluster has formed.
6. Configure the repaired or replacement unit for HA operation with the same HA configuration as the cluster.
7. If the cluster is running in transparent mode, change the operating mode of the repaired or replacement unit to transparent mode.
8. Connect the repaired or replacement cluster unit to the cluster.
For an example see [How to set up FGCP clustering \(recommended steps\) on page 1771](#).
9. Power on the repaired or replacement cluster unit.
When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the repaired or replacement unit configuration with the configuration of the primary unit.

You can add a repaired or replacement unit to a functioning cluster at any time. The repaired or replacement cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.

- Be set to the same operating mode (NAT or transparent) as the cluster.
- Be operating in single VDOM mode.

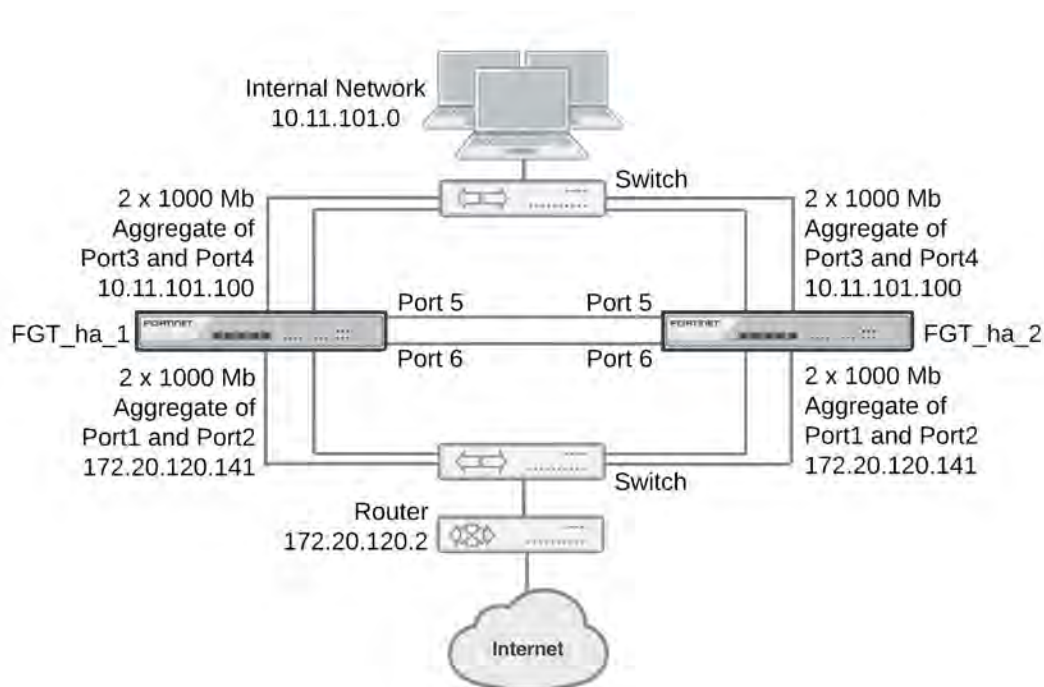

FGCP HA with 802.3ad aggregated interfaces

On FortiGate models that support it you can use 802.3ad link aggregation to combine two or more interfaces into a single aggregated interface. 802.3ad Link Aggregation and its management protocol, Link Aggregation Control Protocol (LACP) are a method for combining multiple physical links into a single logical link. This increases both potential throughput and network resiliency. Using LACP, traffic is distributed among the physical interfaces in the link, potentially resulting in increased performance.

This example describes how to configure an HA cluster consisting of two FortiGates with two aggregated 1000 Mb connections to the Internet using port1 and port2 and two aggregated 1000 Mb connections to the internal network using port3 and port4. The aggregated interfaces are also configured as HA monitored interfaces.

Each of the aggregate links connects to a different switch. Each switch is configured for link aggregation (2x1000Mb).

Example cluster with aggregate interfaces

HA interface monitoring, link failover, and 802.3ad aggregation

When monitoring the aggregated interface, HA interface monitoring treats the aggregated link as a single interface and does not monitor the individual physical interfaces in the link. HA interface monitoring registers the link to have failed only if all the physical interfaces in the link have failed. If only some of the physical interfaces in the link fail or become disconnected, HA considers the link to be operating normally.

HA MAC addresses and 802.3ad aggregation

If a configuration uses the Link Aggregate Control Protocol (LACP) (either passive or active), LACP is negotiated over all of the interfaces in any link. For a standalone FortiGate, the FortiGate LACP implementation uses the MAC address of the first interface in the link to uniquely identify that link. For example, a link consisting of port1 and port2 interfaces would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. An aggregate interface in a cluster acquires the virtual MAC address that would have been acquired by the first interface in the aggregate.

Link aggregation, HA failover performance, and HA mode

To operate an active-active or active-passive cluster with aggregated interfaces and for best performance of a cluster with aggregated interfaces, the switches used to connect the cluster unit aggregated interfaces together should support configuring multiple Link Aggregation (LAG) groups.

For example, the cluster shown above should be configured into two LAG groups on the external switch: one for the port1 and port2 aggregated interface of FGT_ha_1 and a second one for the port1 and port2 aggregate interface of FGT_ha_2. You should also be able to do the same on the internal switch for the port3 and port4 aggregated interfaces of each cluster unit.

As a result, the subordinate unit aggregated interfaces would participate in LACP negotiation while the cluster is operating. In an active-active mode cluster, packets could be redirected to the subordinate unit interfaces. As well, in active-active or active-passive mode, after a failover the subordinate unit can become a primary unit without having to perform LACP negotiation before it can process traffic. Performing LACP negotiation causes a minor failover delay.

However if you cannot configure multiple LAG groups on the switches, due to the primary and subordinate unit interfaces having the same MAC address, the switch will put all of the interfaces into the same LAG group which would disrupt the functioning of the cluster. To prevent this from happening, you must change the FortiGate aggregated interface configuration to prevent subordinate units from participating in LACP negotiation.

For example, use the following command to prevent subordinate units from participating in LACP negotiation with an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

As a result of this setting, subordinate unit aggregated interfaces cannot accept packets. This means that you cannot operate the cluster in active-active mode because in active-active mode the subordinate units must be able to receive and process packets. Also, failover may take longer because after a failover the subordinate unit has to perform LACP negotiation before being able to process network traffic.

Also, it may also be necessary to configure the switch to use Passive or even Static mode for LACP to prevent the switch from sending packets to the subordinate unit interfaces, which won't be able to process them.

Finally, in some cases depending on the LACP configuration of the switches, you may experience delayed failover if the FortiGate LACP configuration is not compatible with the switch LACP configuration. For example, in some cases setting the FortiGate LACP mode to static reduces the failover delay because the FortiGate does not perform LACP negotiation. However there is a potential problem with this configuration because static LACP does not send periodic LAC Protocol Data Unit (LACPDU) packets to test the connections. So a non-physical failure (for example, if a device is not responding because its too busy) may not be detected and packets could be lost or delayed.

General configuration steps

The section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.
 - Change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the aggregated interfaces.
 - Add a password for the admin administrative account.
 - Add the aggregated interfaces.
 - Disable `lacp-ha-slave` so that the subordinate unit does not send LACP packets.
 - Add a default route.

You could also configure aggregated interfaces in each FortiGate before the units form a cluster.

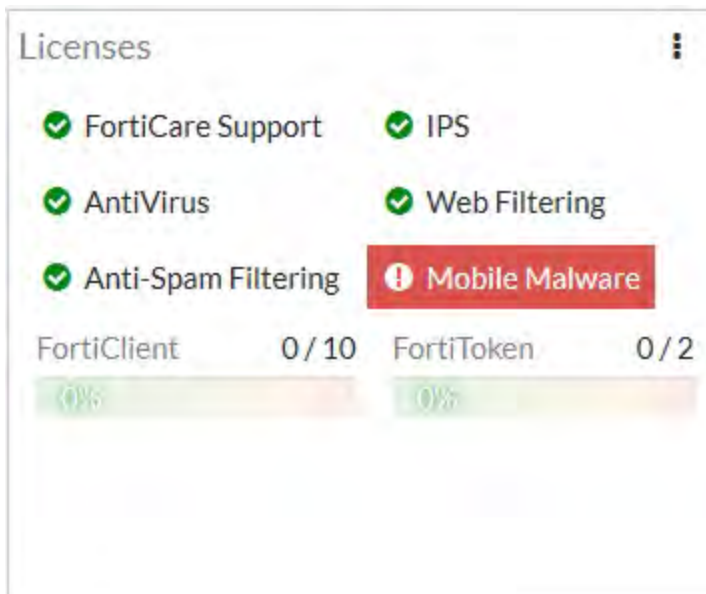

5. Configure HA port monitoring for the aggregated interfaces.

Configuring active-passive HA cluster that includes aggregated interfaces - GUI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings.

Mode	Active-Passive	
Group Name	example5.com	
Password	HA_pass_5	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration to not use those interfaces.

6. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11

- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate.
8. Repeat these steps for the second FortiGate.

Set the second FortiGate host name to:

New Name	FGT_ha_2

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up a second aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up an aggregated interface and port3 and port4 of FGT_ha_2 make up another aggregated interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete, the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed) You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.

2. Go to **System > HA** to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a aggregated interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** to add the aggregate interface to connect to the Internet.
8. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the Internet:

Name	Port1_Port2
Interface Members	port1, port2
IP/Network Mask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New > Interface** to add the aggregate interface to connect to the internal network.
11. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the Internet:

Name	Port3_Port4
Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Connect to the CLI and enter the following command to disable sending LACP packets from the subordinate unit:

```
config system interface
    edit Port1_Port2
        set lacp-ha-slave disable
    next
    edit Port3_Port4
        set lacp-ha-slave disable
end
```

14. Go to **Network > Static Routes**.

15. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

16. Select **OK**.

To configure HA port monitoring for the aggregate interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the aggregate interfaces:

Port Monitor	
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes aggregate interfaces - CLI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.
2. Install any third-party certificates on the FortiGate.
3. Change the host name for this FortiGate:

```
config system global
    set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example5.com
    set password HA_pass_5
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06

- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate.

Set the other FortiGate host name to:

```
config system global
    set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up another aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up an interfaced and port3 and port4 of FGT_ha_2 make up another aggregated interface.

3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to view the status of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1845](#) to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings and the aggregate interfaces.

1. Add a password for the admin administrative account.

```

config system admin
  edit admin
    set password <psswr>
  end

```

2. Temporarily delete the default route.

You cannot add an interface to an aggregate interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```

config router static
  delete 1
end

```

3. Add the aggregate interfaces:

```

config system interface
  edit Port1_Port2
    set type aggregate
    set lacp-ha-slave disable
    set member port1 port2
    set ip 172.20.120.141/24
    set vdom root
  next
  edit Port3_Port4
    set type aggregate
    set lacp-ha-slave disable
    set member port3 port4
    set ip 10.11.101.100/24
    set vdom root
  end
end

```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10

- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

4. Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
  end
```

To configure HA port monitoring for the aggregate interfaces

1. Configure HA port monitoring for the aggregate interfaces.

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Example HA and redundant interfaces

On FortiGate models that support it you can combine two or more interfaces into a single redundant interface. A redundant interface consists of two or more physical interfaces. Traffic is processed by the first physical interface in the redundant interface. If that physical interface fails, traffic fails over to the next physical interface. Redundant interfaces don't have the benefit of improved performance that aggregate interfaces can have, but they do provide failover if a physical interface fails or is disconnected.

Example cluster with a redundant interfaces

This example describes how to configure an HA cluster consisting of two FortiGates with a redundant interface connection to the Internet and to an internal network. The connection to the Internet uses port1 and port2. The connection to the internal network uses port3 and port4. The HA heartbeat uses port5 and port6.

The redundant interfaces are also configured as HA monitored interfaces.

HA interface monitoring, link failover, and redundant interfaces

HA interface monitoring monitors the redundant interface as a single interface and does not monitor the individual physical interfaces in the redundant interface. HA interface monitoring registers the redundant interface to have failed only if all the physical interfaces in the redundant interface have failed. If only some of the physical interfaces in the redundant interface fail or become disconnected, HA considers the redundant interface to be operating normally.

HA MAC addresses and redundant interfaces

For a standalone FortiGate a redundant interface has the MAC address of the first physical interface added to the redundant interface configuration. A redundant interface consisting of port1 and port2 would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. A redundant interface in a cluster acquires the virtual MAC address that would have been acquired by the first physical interface added to the redundant interface configuration.

Connecting multiple redundant interfaces to one switch while operating in active-passive HA mode

HA assigns the same virtual MAC addresses to the subordinate unit interfaces as are assigned to the corresponding primary unit interfaces. Consider a cluster of two FortiGates operating in active-passive mode with a redundant interface consisting of port1 and port2. You can connect multiple redundant interfaces to the same switch if you configure the switch so that it defines multiple separate redundant interfaces and puts the redundant interfaces of each cluster unit into separate redundant interfaces. In this configuration, each cluster unit forms a separate redundant interface with the switch.

However, if the switch is configured with a single four-port redundant interface configuration, because the same MAC addresses are being used by both cluster units, the switch adds all four interfaces (port1 and port2 from the primary unit and port1 and port2 from the subordinate unit) to the same redundant interface.

To avoid unpredictable results, when you connect a switch to multiple redundant interfaces in an active-passive cluster you should configure separate redundant interfaces on the switch; one for each cluster unit.

Connecting multiple redundant interfaces to one switch while operating in active-active HA mode

In an active-active cluster, all cluster units send and receive packets. To operate a cluster with redundant interfaces in active-active mode, with multiple redundant interfaces connected to the same switch, you must separate the redundant interfaces of each cluster unit into different redundant interfaces on the connecting switch.

General configuration steps

The section includes GUI and CLI procedures. These procedures assume that the FortiGates are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGates to become the cluster.
2. Configure the FortiGates for HA operation.

- Change each unit's host name.
 - Configure HA.
2. Connect the cluster to the network.
 3. View cluster status.
 4. Add basic configuration settings and configure the redundant interfaces.
 - Add a password for the admin administrative account.
 - Add the redundant interfaces.
 - Add a default route.

You could also configure redundant interfaces in each FortiGate before they form a cluster.

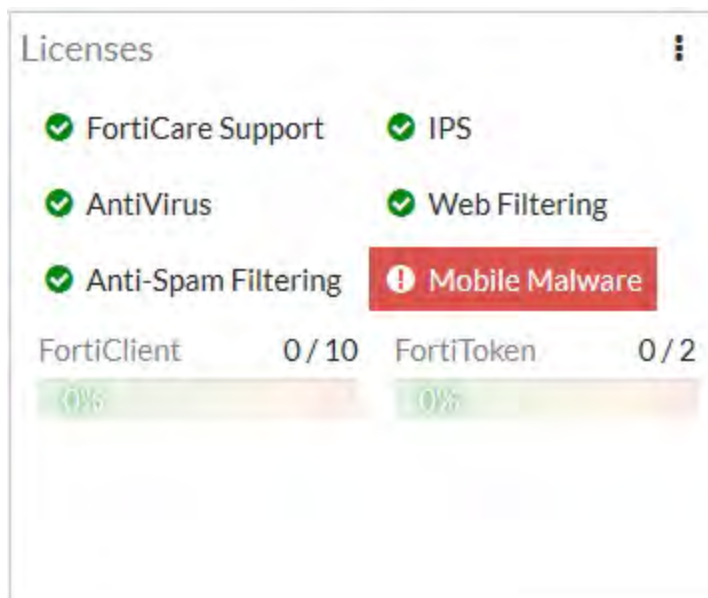

5. Configure HA port monitoring for the redundant interfaces.

Configuring active-passive HA cluster that includes redundant interfaces - GUI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Select **OK**.
5. Go to **System > HA** and change the following settings.

Mode	Active-Passive
-------------	----------------

Group Name	example6.com	
Password	HA_pass_6	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

6. Select OK.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following

command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate.
8. Repeat these steps for the second FortiGate.
Set the second FortiGate host name to:

New Name	FGT_ha_2
----------	----------

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.
The HA Status dashboard widget displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change. You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.
2. Go to **System > HA** to view the cluster members list.
The list shows both cluster units, their host names, their roles in the cluster, and their device priorities.

You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1845](#).

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** to add the redundant interface to connect to the Internet.
8. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the Internet:

Name	Port1_Port2
Physical Interface Members	port1, port2
IP/Netmask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New** to add the redundant interface to connect to the internal network.
11. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the Internet:

Name	Port3_Port4
Physical Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.
The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:
 - port1 interface virtual MAC: 00-09-0f-09-00-00
 - port10 interface virtual MAC: 00-09-0f-09-00-01
 - port11 interface virtual MAC: 00-09-0f-09-00-02

- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Go to **Router > Static > Static Routes**.

14. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

15. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes redundant interfaces - CLI

These procedures assume you are starting with two FortiGates with factory default settings.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). All of the FortiGates in a cluster must have the same level of licensing.
2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
We recommend that you add FortiToken licenses and FortiTokens to the primary unit after the cluster has formed.
3. Change the host name for this FortiGate:

```
config system global
    set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example6.com
    set password HA_pass_6
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

The FortiGate negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate.

Set the other FortiGate host name to:

```
config system global
    set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet. Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network. Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

To troubleshoot the cluster configuration

See [Troubleshooting HA clusters on page 1845](#).

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings and the redundant interfaces.

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

2. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

3. Add the redundant interfaces:

```
config system interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
```

```

        set ip 172.20.120.141/24
        set vdom root
    next
    edit Port3_Port4
        set type redundant
        set member port3 port4
        set ip 10.11.101.100/24
        set vdom root
    end

```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

4. Add the default route.

```

config router static
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set gateway 172.20.120.2
        set device Port1_Port2
    end

```

To configure HA port monitoring for the redundant interfaces

1. Configure HA port monitoring for the redundant interfaces.

```

config system ha
    set monitor Port1_Port2 Port3_Port4
end

```

Troubleshooting HA clusters

This section describes some HA clustering troubleshooting techniques.

Ignoring hardware revisions

Many FortiGate platforms have gone through multiple hardware versions and in some cases the hardware changes prevent cluster formation. If you run into this problem you can use the following command on each FortiGate to cause the cluster to ignore different hardware versions:

```
execute ha ignore-hardware-revision enable
```

This command is only available on FortiGates that have had multiple hardware revisions.

By default the command is set to prevent cluster formation between FortiGates with different hardware revisions. You can enter the following command to view its status:

```
execute ha ignore-hardware-revision status
```

Usually the incompatibility is caused by different hardware versions having different hard disks and enabling this command disables each FortiGate's hard disks. As a result of disabling hard disks the cluster will not support logging to the hard disk or WAN Optimization.

If the FortiGates do have compatible hardware versions or if you want to run a FortiGate in standalone mode you can enter the following command to disable ignoring the hardware revision and enable the hard disks:

```
execute ha ignore-hardware-revision disable
```

Affected models include but are not limited to:

- FortiGate-100D
- FortiGate-300C
- FortiGate-600C
- FortiGate-800C
- FortiGate-80C and FortiWiFi-80C
- FortiGate-60C

It's possible that a cluster will not form because the disk partition sizes of the cluster units are different. You can use the `diagnose sys ha checksum test | grep storage` command to check the disk storage checksum of each cluster unit. If the checksums are different then visit the [Fortinet Support](#) website for help in setting up compatible storage partitions.

Before you set up a cluster

Before you set up a cluster ask yourself the following questions about the FortiGates that you are planning to use to create a cluster.

1. Do all the FortiGates have the same hardware configuration? Including the same hard disk configuration?
2. Do all of the FortiGates have the same FortiGuard, FortiCloud, FortiClient, VDOM and FortiOS Carrier licensing?
3. Do all the FortiGates have the same firmware build?
4. Are all the FortiGates set to the same operating mode (NAT or transparent)?
5. Are all the FortiGates operating in single VDOM mode?
6. If the FortiGates are operating in multiple VDOM mode do they all have the same VDOM configuration?

In some cases you may be able to form a cluster if different FortiGates have different firmware builds, different VDOM configurations, and are in different operating modes. However, if you encounter problems they may be resolved by installing the same firmware build on each unit, and give them the same VDOM configuration and operating mode. If the FortiGates in the cluster have different licenses, the cluster will form but it will operate with the lowest licensing level.

Troubleshooting the initial cluster configuration

This section describes how to check a cluster when it first starts up to make sure that it is configured and operating correctly. This section assumes you have already configured your HA cluster.

To verify that a cluster can process traffic and react to a failure

1. Add a basic security policy configuration and send network traffic through the cluster to confirm connectivity.
For example, if the cluster is installed between the Internet and an internal network, set up a basic internal to external security policy that accepts all traffic. Then from a PC on the internal network, browse to a website on the Internet or ping a server on the Internet to confirm connectivity.
2. From your management PC, set ping to continuously ping the cluster, and then start a large download, or in some other way establish ongoing traffic through the cluster.
3. While traffic is going through the cluster, disconnect the power from one of the cluster units.
You could also shut down or restart a cluster unit.
Traffic should continue with minimal interruption.
4. Start up the cluster unit that you disconnected.
The unit should re-join the cluster with little or no affect on traffic.
5. Disconnect a cable from one of the HA heartbeat interfaces.
The cluster should keep functioning, using the other HA heartbeat interface.
6. If you have port monitoring enabled, disconnect a network cable from a monitored interface.
Traffic should continue with minimal interruption.

To verify the cluster configuration from the GUI

Use these steps if a cluster is formed just to verify its status and configuration.

1. Log into the cluster GUI.
2. Check the system dashboard to verify that the System Information widget displays all of the cluster units.
3. Check the Unit Operation widget graphic to verify that the correct cluster unit interfaces are connected.
4. Go to **System > HA** or from the System Information dashboard widget select **HA Status > Configure** and verify that all of the cluster units are displayed on the HA Cluster list.
5. From the cluster members list, edit the primary unit (master) and verify the cluster configuration is as expected.

To troubleshoot the cluster configuration from the GUI

Use these steps if the FortiGates don't successfully form a cluster:

1. Connect to each cluster unit GUI and verify that the HA configurations are the same. The HA configurations of all of the cluster units must be identical. Even though the HA configuration is very simple you can easily make a small

mistake that prevents a FortiGate from joining a cluster.

2. If the configurations are the same, try re-entering the HA **Password** on each cluster unit in case you made an error typing the password when configuring one of the cluster units.
3. Check that the correct interfaces of each cluster unit are connected.
Check the cables and interface LEDs.

Use the Unit Operation dashboard widget, system network interface list, or cluster members list to verify that each interface that should be connected actually is connected.

If the link is down re-verify the physical connection. Try replacing network cables or switches as required.

To verify the cluster configuration from the CLI

Use these steps if a cluster is formed just to verify its status and configuration.

1. Log into each cluster unit CLI.
You can use the console connection if you need to avoid the problem of units having the same IP address.
2. Enter the command `get system status`.
Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Verify that the `get system ha status` command shows that the cluster health is OK and shows that all of the cluster units have joined the cluster.
4. Enter the `get system ha` command to verify that the HA configuration is correct and the same for each cluster unit.

To troubleshoot the cluster configuration from the CLI

Try these steps if the FortiGates don't successfully form a cluster:

1. Try using the following command to re-enter the cluster password on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

```
config system ha
  set password <password>
end
```

2. Check that the correct interfaces of each cluster unit are connected.
Check the cables and interface LEDs.

Use `get hardware nic <interface_name>` command to confirm that each interface is connected. If the interface is connected the command output should contain a `Link: up` entry similar to the following:

```

get hardware nic port1
.
.
.
Link: up
.
.
.

```

If the link is down, re-verify the physical connection. Try replacing network cables or switches as required.

More troubleshooting information

Much of the information in this HA guide can be useful for troubleshooting HA clusters. Here are some links to sections with more information.

- If sessions are lost after a failover you may need to change route-ttl to keep synchronized routes active longer. See [Synchronizing kernel routing tables on page 1933](#)
- To control which cluster unit becomes the primary unit, you can change the device priority and enable override. See [Controlling primary unit selection using device priority and override on page 1754](#)
- Changes made to a cluster can be lost if override is enabled. See [Configuration changes can be lost if override is enabled on page 1755](#)
- When override is enabled, after a failover traffic may be disrupted if the primary unit rejoins the cluster before the session tables are synchronized or for other reasons such as if the primary unit is configured for DHCP or PPPoE. See [Delaying how quickly the primary unit rejoins the cluster when override is enabled on page 1756](#).
- In some cases, age differences among cluster units result in the wrong cluster unit becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units. You can resolve this problem by resetting the age of one or more cluster units. See [Primary unit selection and age on page 1747](#) You can also adjust how sensitive the cluster is to age differences. This can be useful if large age differences cause problems. See [Cluster age difference margin \(grace period\) on page 1747](#) and [Changing the cluster age difference margin on page 1748](#).
- If one of the cluster units needs to be serviced or removed from the cluster for other reasons, you can do so without affecting the operation of the cluster. See [Disconnecting a cluster unit from a cluster on page 1905](#)
- The GUI and CLI will not allow you to configure HA if you have enabled FGSP HA. See [FortiGate Session Life Support Protocol \(FGSP\) on page 1991](#).
- The GUI and CLI will not allow you to configure HA if one or more FortiGate interfaces is configured as a PPTP or L2TP client.
- The FGCP is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. See [FortiGate HA compatibility with DHCP and PPPoE on page 1756](#).
- Some third-party network equipment may prevent HA heartbeat communication, resulting in a failure of the cluster or the creation of a split brain scenario. For example, some switches use packets with the same Ethertype as HA heartbeat packets use for internal functions and when used for HA heartbeat communication the switch generates CRC errors and the packets are not forwarded. See [Heartbeat packet Ethernets on page 1915](#).
- Very busy clusters may not be able to send HA heartbeat packets quickly enough, also resulting in a split brain scenario. You may be able to resolve this problem by modifying HA heartbeat timing. See [Modifying heartbeat timing on page 1916](#).

- Very busy clusters may suffer performance reductions if session pickup is enabled. If possible you can disable this feature to improve performance. If you require session pickup for your cluster, several options are available for improving session pickup performance. See [Improving session synchronization performance on page 1954](#).
- If it takes longer than expected for a cluster to failover you can try changing how the primary unit sends gratuitous ARP packets. See [Changing how the primary unit sends gratuitous ARP packets after a failover on page 1919](#).
- You can also improve failover times by configuring the cluster for sub-second failover. See [Sub-second failover on page 1942](#) and [Failover performance on page 1951](#).
- When you first put a FortiGate in HA mode you may lose connectivity to the unit. This occurs because HA changes the MAC addresses of all FortiGate interfaces, including the one that you are connecting to. The cluster MAC addresses also change if you change some HA settings such as the cluster group ID. The connection will be restored in a short time as your network and PC updates to the new MAC address. To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
- Since HA changes all cluster unit MAC addresses, if your network uses MAC address filtering you may have to make configuration changes to account for the HA MAC addresses.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See [Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1923](#).
- The cluster CLI displays `slave is not in sync` messages if there is a synchronization problem between the primary unit and one or more subordinate units. See [How to diagnose HA out of sync messages on page 1931](#).
- If you have configured dynamic routing and the new primary unit takes too long to update its routing table after a failover you can configure graceful restart and also optimize how routing updates are synchronized. See [Configuring graceful restart for dynamic routing failover on page 1935](#) and [Synchronizing kernel routing tables on page 1933](#).
- Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur after a link failover if the switch does not detect the failure and does not clear its MAC forwarding table. See [Updating MAC forwarding tables when a link failover occurs on page 1940](#).
- If a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails you can enable remote link failover to maintain communication. See [Remote link failover \(remote IP monitoring\) on page 1943](#).
- If you find that some cluster units are not running the same firmware build you can reinstall the correct firmware build on the cluster to upgrade all cluster units to the same firmware build. See [Synchronizing the firmware build running on a new cluster unit on page 1895](#).

Virtual clusters

This chapter describes virtual clustering, a variation of the FGCP for FortiGates with multiple VDOMs. Virtual clustering includes can operate in active-passive or active-active HA mode for clusters of up to four FortiGates. Active-passive virtual clustering includes VDOM partitioning that to distribute traffic for different VDOMs between the primary and backup FortiGates.

Virtual clustering overview

Virtual clustering is an extension of the FGCP that provides failover protection between two instances of one or more VDOMs operating on two FortiGates in a virtual cluster.

A standard virtual cluster consists of up to four FortiGates operating in active-passive or active-active HA mode with multiple VDOMS enabled.

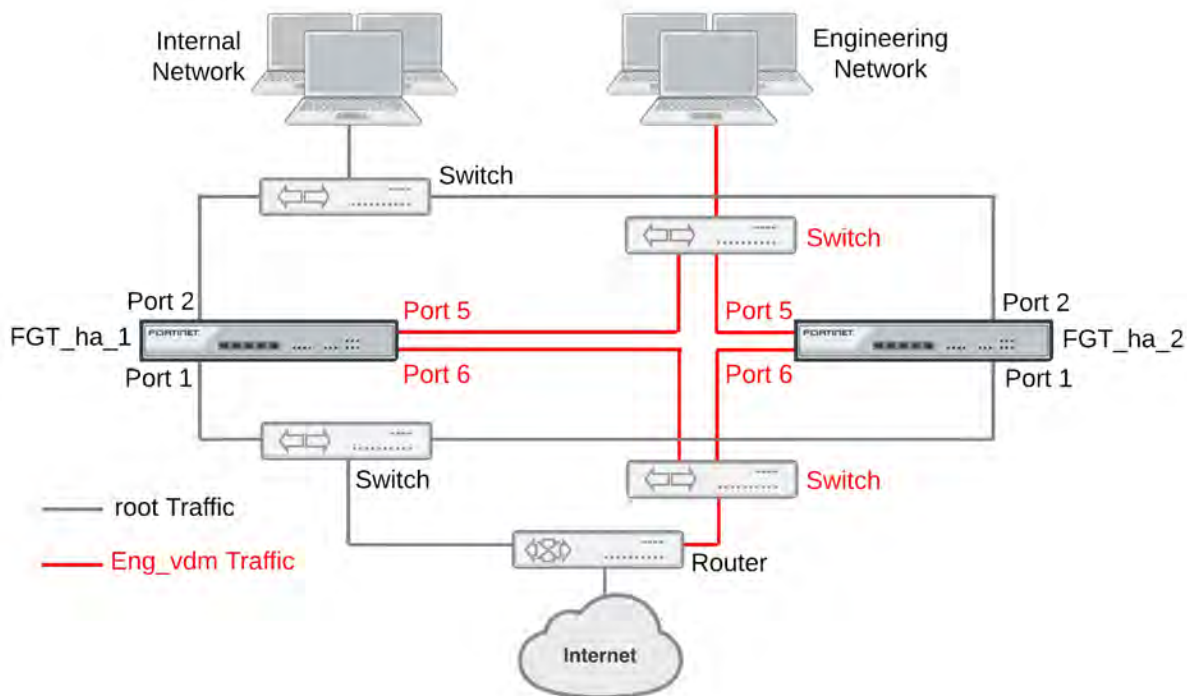

Active-passive virtual clustering uses VDOM partitioning to send traffic for some VDOMs to the primary FortiGate and traffic for other VDOMs to the backup FortiGate. Traffic distribution between both FortiGates can potentially improve throughput. If a failure occurs and only one FortiGate continues to operate, all traffic fails over to that FortiGate, similar to normal HA. If the failed FortiGates restart, the configured traffic distribution is restored.

Active-active virtual clustering operates just the same as standard FGCP active-active HA, distributing traffic to all of the FortiGates in the cluster using FGCP load balancing.

In an active-passive virtual cluster of two FortiGates, the primary and backup FortiGates share traffic processing according to the VDOM partitioning configuration. If you add a third or fourth FortiGate, the primary and first backup FortiGate process all traffic and the other one or two FortiGates operate in standby mode. If the primary or first backup FortiGate fails, one of the other FortiGates becomes the new primary or backup FortiGate and begins processing traffic.

The figure below shows an example virtual cluster configuration consisting of two FortiGates. The virtual cluster has two VDOMs, root and Eng_vdm.

Example virtual cluster

The root VDOM includes the port1 and port2 interfaces. The Eng_vdm VDOM includes the port5 and port6 interfaces. The port3 and port4 interfaces (not shown in the diagram) are the HA heartbeat interfaces.

If you don't want active-passive virtual clustering to distribute traffic between FortiGates, you can configure VDOM partitioning to send traffic for all VDOMs to the primary unit. The result is the same as standard active-passive FCGP HA, all traffic is processed by the primary FortiGate.

Separation of VDOM traffic

Virtual clustering creates a cluster between instances of each VDOM on the two FortiGates in the virtual cluster. All traffic to and from a given VDOM is sent to one of the FortiGates where it stays within its VDOM and is only processed by that VDOM. One FortiGate is the primary FortiGate for each VDOM and one FortiGate is the backup FortiGate for each VDOM. The primary FortiGate processes all traffic for its VDOMs. The backup FortiGate processes all traffic for its VDOMs.

If your cluster has a VLAN that is part of a different VDOM than the physical interface that the VLAN has been added to, then you must configure VDOM partitioning to keep traffic for both of these VDOMs on the same FortiGate.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Virtual clustering and load balancing

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary FortiGate receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

In an active-passive virtual clustering configuration, you can configure a form of load balancing by using VDOM partitioning to distribute traffic between the primary and backup FortiGates. While a cluster is operating, you can change the VDOM partitioning configuration to change the distribution of traffic between the cluster units. For example, if you have two VDOMs with high traffic volume you can set up VDOM partitioning so that different FortiGates process the traffic for each high-volume VDOM. If over time traffic patterns change you can dynamically re-adjust VDOM partitioning to optimize traffic throughput. VDOM partitioning can be changed at any with only minor traffic disruptions.

Configuring virtual clustering

Configuring virtual clustering is the same as configuring standard FCGP HA with the addition of VDOM partitioning. Using VDOM partitioning you can control the distribution of VDOMs, and the traffic they process, between the FortiGates in the cluster.

VDOM partitioning can be thought of in two parts. First there is configuring the distribution of VDOMs between two virtual clusters. By default, all VDOMs are in virtual cluster 1 and virtual cluster 1 is associated with the primary FortiGate. In this configuration, the primary FortiGate processes all traffic. If you want traffic to be processed by the backup FortiGate, you need to enable virtual cluster 2, move some of the VDOMs to it, and associate virtual cluster 2 with the backup FortiGate.

Since there are only two virtual clusters, even in a virtual clustering configuration of three or four FortiGates only two of the FortiGates process traffic. The third and fourth FortiGates operate in standby mode and process traffic after a failover.

By default all VDOMs are in virtual cluster 1 and the primary FortiGate processes all traffic.

You associate a virtual cluster with a FortiGate using priorities. The FortiGate with the highest device priority is associated with virtual cluster 1. To associate a FortiGate with virtual cluster 2 you must enable virtual cluster 2 and set the virtual cluster 2 device priority. The FortiGate with the highest virtual cluster 2 device priority processes traffic for the VDOMs added to virtual cluster 2. (Reminder: device priorities are not synchronized.)

If both FortiGates have the same device priority, virtual cluster 1 is associated with the primary FortiGate. If both FortiGates have the same virtual cluster 2 device priority, virtual cluster 2 is associated with the primary FortiGate.

Virtual clustering and the override setting

Enabling virtual cluster 2 also turns on the HA override setting. Enabling override is required for virtual clustering to function as configured. Enabling override causes the cluster to negotiate every time a failure occurs. If override is not enabled, the cluster will not negotiate after all failures. While more frequent negotiation may cause more minor traffic disruptions, with virtual clustering its more important to negotiate after any failure to make sure the correct traffic flows are maintained.

Example virtual clustering configuration

For example, consider a configuration that includes four VDOMs: root, Engineering, Marketing, and Finance. You can use the following configuration to send root and Engineering traffic to the primary FortiGate and Marketing and Finance traffic to the backup FortiGate.

First, on the primary FortiGate:

- Set the device priority to 200
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 50
- Add the Marketing and Finance VDOMs to virtual cluster 2 (secondary-vcluster)

When you enable multiple VDOMs, virtual cluster 2 is enabled by default. Even so the command to enable virtual cluster 2 is included in this example in case for some reason it has been disabled. Enabling virtual cluster 2 also enables override.

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 200
    set vcluster2 enable
    config secondary-vcluster
      set vdom Marketing Finance
      set priority 50
    end
  end
end
```

Then on the backup FortiGate:

- Set the device priority to 50 (lower than the primary FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 200 (higher than the primary FortiGate).

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 50
    set vcluster2 enable
    config secondary-vcluster
      set priority 200
    end
  end
end
```

Since the primary FortiGate has the highest device priority, the primary unit processes all traffic for the VDOMs in virtual cluster 1. Since the backup FortiGate has the highest virtual cluster 2 device priority, the backup FortiGate processes all traffic for the VDOMs in virtual cluster 2. The primary FortiGate configuration adds the VDOMs to virtual cluster 2. All you have to configure on the backup FortiGate for virtual cluster 2 is the virtual cluster 2 (or secondary-vcluster) device priority.

Adding a third FortiGate to the virtual cluster

You can add a third FortiGate to the virtual cluster and configure it so that if the primary FortiGate fails, the third FortiGate becomes the new primary FortiGate or if the backup FortiGate fails, the third FortiGate becomes the new backup FortiGate.

On the third FortiGate:

- Set the device priority to 150 (lower than the primary FortiGate but higher than the backup FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 100 (higher than the primary FortiGate but lower than the backup FortiGate)

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 150
    set vcluster2 enable
    config secondary-vcluster
      set priority 100
    end
  end
end
```

Adding a fourth FortiGate to the virtual cluster

You can add a fourth FortiGate to the virtual cluster and configure it so that:

- If the primary FortiGate fails, the third FortiGate becomes the new primary FortiGate, the backup FortiGate continues to operate as the backup FortiGate.
- If the backup FortiGate fails, the fourth FortiGate becomes the new backup FortiGate.
- If both the primary and backup FortiGates fail, the third FortiGate becomes the primary FortiGate and the fourth FortiGate becomes the backup FortiGate.

On the fourth FortiGate:

- Set the device priority to 100 (lower than the primary and third FortiGate but higher than the backup FortiGate)
- Enable virtual cluster 2 (vcluster2)
- Set the virtual cluster 2 device priority (secondary-vcluster) to 150 (higher than the primary FortiGate and the third FortiGate but lower than the backup FortiGate)

```
config global
  config system ha
    set mode a-p
    set group-name mygroup
    set password <password>
    set priority 100
```

```
set vcluster2 enable
config secondary-vcluster
    set priority 150
end
end
```

Virtual clustering with four FortiGates recommended configuration

As described in the previous sections, here is a recommended device priority configuration for a virtual cluster consisting of four FortiGates. Other configurations are also supported depending on how you want the virtual cluster to respond to a failure.

FortiGate	Device Priority	Virtual Cluster 2 Device Priority
Primary	200	50
Backup	50	100
Third	150	200
Fourth	100	150

Virtual clustering GUI configuration

From the GUI, you configure virtual clustering from the Global menu by going to **System > HA** setting the **Mode** to **Active-Passive** and enabling **VDOM Partitioning**.

Example primary FortiGate virtual clustering configuration

Mode	Active-Passive
Device priority ⓘ	200

Cluster Settings

Group name	My-vcluster	
Password	Change
Session pickup	<input type="checkbox"/>	
Monitor interfaces	<div> wan1 ×</div> <div>+</div>	
Heartbeat interfaces	<div><div> lan4 ×</div><div> lan5 ×</div><div>+</div></div>	

Heartbeat Interface Priority ⓘ

Virtual clustering configuration examples

See the following cookbook recipe for a virtual clustering configuration example. This example shows how to set up a virtual cluster of two FortiGates and then how to add a third and fourth FortiGate to the virtual cluster configuration.

- [FGCP virtual clustering with two FortiGates](#)
- [FGCP virtual clustering with two FortiGates](#)

Example inter-VDOM links in a virtual clustering configuration

In a virtual domain configuration you can use inter-VDOM links to route traffic between two virtual domains operating in a single FortiGate without using physical interfaces. Adding an inter-VDOM link has the affect of adding two interfaces to the FortiGate and routing traffic between the virtual domains using the inter-VDOM link interfaces.

In a virtual clustering configuration inter-VDOM links can only be made between virtual domains that are in the same virtual cluster. So, if you are planning on configuring inter-VDOM links in a virtual clustering configuration, you should make sure the virtual domains that you want to link are in the same virtual cluster.

For example, the following tables show an example virtual clustering configuration where each virtual cluster contains four virtual domains. In this configuration you can configure inter-VDOM links between root and vdom_1 and between vdom_2 and vdom_3. But, you cannot configure inter-VDOM links between root and vdom_2 or between vdom_1 and vdom_3 (and so on).

Hostname		
Virtual Domains	FortiGate_A	FortiGate_B
root	Priority	Priority
	200	100
vdom_1	Role	Role
	Primary	Subordinate

Hostname		
Virtual Domains	FortiGate_A	FortiGate_B
vdom_2	Priority	Priority
	100	200
vdom_3	Role	Role
	Subordinate	Primary

Configuring inter-VDOM links in a virtual clustering configuration

Configuring inter-VDOM links in a virtual clustering configuration is very similar to configuring inter-VDOM links for a standalone FortiGate. The main difference the `config system vdom-link` command includes the `vcluster` keyword. The default setting for `vcluster` is `vcluster1`. So you only have to use the `vcluster` keyword if you are added an inter-VDOM link to virtual cluster 2.

To add an inter-VDOM link to virtual cluster 1

This procedure describes how to create an inter-VDOM link to virtual cluster 1 that results in a link between the root and vdom_1 virtual domains.

Inter-VDOM links are also called internal point-to-point interfaces.

1. Add an inter-VDOM link called `vc1link`.

```
config global
  config system vdom-link
  edit vc1link
end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc1link0` and `vc1link1`. These interfaces appear in all CLI and GUI interface lists. These interfaces can only be added to virtual domains in virtual cluster 1.

2. Bind the `vc1link0` interface to the root virtual domain and bind the `vc1link1` interface to the `vdom_1` virtual domain.

```
config system interface
  edit vc1link0
    set vdom root
  next
  edit vc1link1
    set vdom vdom_1
end
```

To add an inter-VDOM link to virtual cluster 2

This procedure describes how to create an inter-VDOM link to virtual cluster 2 that results in a link between the `vdom_2` and `vdom_3` virtual domains.

1. Add an inter-VDOM link called `vc2link`.

```
config global
  config system vdom-link
  edit vc2link
    set vcluster vcluster2
end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc2link0` and `vc2link1`. These interfaces appear in all CLI and GUI interface lists. These interfaces can only be added to virtual domains in virtual cluster 2.

2. Bind the `vc2link0` interface to the `vdom_2` virtual domain and bind the `vc2link1` interface to the `vdom_3` virtual domain.

```
config system interface
  edit vc2link0
    set vdom vdom_2
  next
  edit vc2link1
    set vdom vdom_3
end
```

Troubleshooting virtual clustering

Troubleshooting virtual clusters is similar to troubleshooting any cluster (see [FGCP configuration examples and troubleshooting on page 1771](#)). This section describes a few testing and troubleshooting techniques for virtual clustering.

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for different VDOMs will be distributed among both FortiGates in the virtual cluster. These steps assume the cluster is otherwise operating correctly.

1. Log into the GUI or CLI using the IP addresses of interfaces in each VDOM.
Confirm that you have logged into the FortiGate that should be processing traffic for that VDOM by checking the HTML title displayed by your web browser or the CLI prompt. Both of these should include the host name of the cluster unit that you have logged into. Also on the system Dashboard, the System Information widget displays the serial number of the FortiGate that you logged into. From the CLI the `get system status` command displays the status of the cluster unit that you logged into.
2. To verify that the correct cluster unit is processing traffic for a VDOM:
 - Add security policies to the VDOM that allow communication between the interfaces in the VDOM.
 - Optionally enable traffic logging and other monitoring for that VDOM and these security policies.
 - Start communication sessions that pass traffic through the VDOM.
 - Log into the GUI and go to **System > HA**. Verify that the statistics display shows more active sessions, total packets, network utilization, and total bytes for the unit that should be processing all traffic for the VDOM.
 - Optionally check traffic logging and the Top Sessions Widget for the FortiGate that should be processing traffic for that VDOM to verify that the traffic is being processed by this FortiGate.

Full mesh HA

This chapter provides an introduction to full mesh HA and also contains general procedures and configuration examples that describe how to configure FortiGate full mesh HA.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

Full mesh HA overview

When two or more FortiGates are connected to a network in an HA cluster the reliability of the network is improved because the HA cluster replaces a single FortiGate as a single point of failure. With a cluster, a single FortiGate is replaced by a cluster of two or more FortiGates.

However, even with a cluster, potential single points of failure remain. The interfaces of each cluster unit connect to a single switch and that switch provides a single connection to the network. If the switch fails or if the connection between the switch and the network fails service is interrupted to that network.

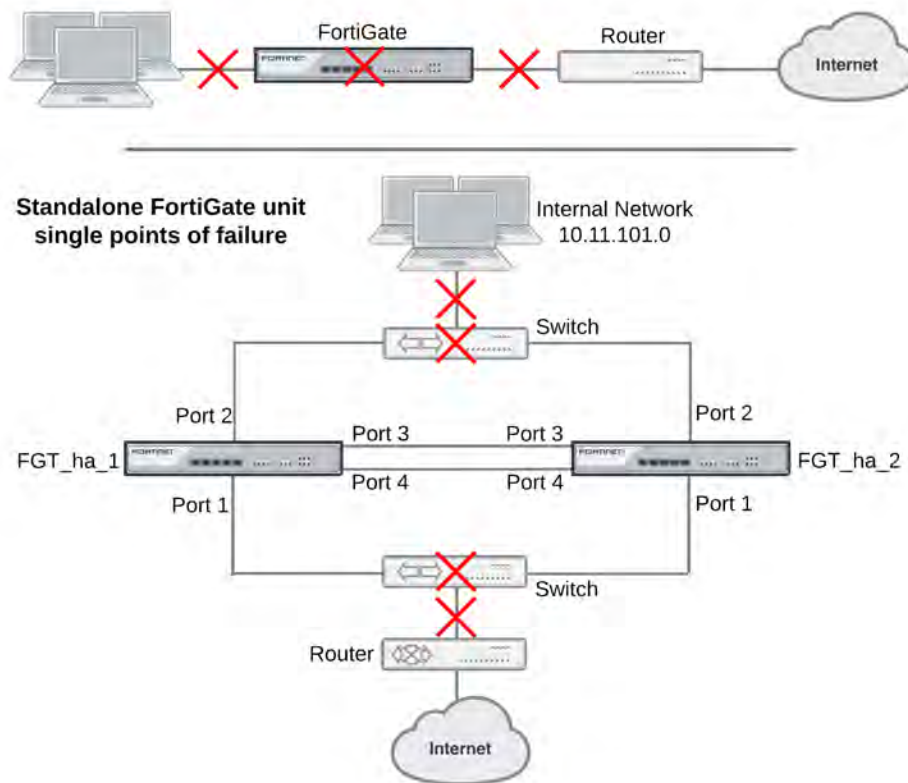

The HA cluster does improve the reliability of the network because switches are not as complex components as FortiGates, so are less likely to fail. However, for even greater reliability, a configuration is required that includes redundant connections between the cluster the networks that it is connected to.

FortiGate models that support 802.3ad Aggregate or Redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster.

This redundant configuration can be achieved using FortiGate 802.3ad Aggregate or Redundant interfaces and a full mesh HA configuration. In a full mesh HA configuration, you connect an HA cluster consisting of two or more FortiGates to the network using 802.3ad Aggregate or Redundant interfaces and redundant switches. Each 802.3ad Aggregate or Redundant interface is connected to two switches and both of these switches are connected to the network. In addition you must set up an IEEE 802.1Q (also called Dot1Q) or ISL link between the redundant switches connected to the Aggregate or Redundant interfaces.

The resulting full mesh configuration, an example is shown below, includes redundant connections between all network components. If any single component or any single connection fails, traffic automatically switches to the redundant component and connection and traffic flow resumes.

Single points of failure in a standalone and HA network configuration

Full mesh HA and redundant heartbeat interfaces

A full mesh HA configuration also includes redundant HA heartbeat interfaces. At least two heartbeat interfaces should be selected in the HA configuration and both sets of HA heartbeat interfaces should be connected. The HA heartbeat interfaces do not have to be configured as redundant interfaces because the FGCP handles failover between heartbeat interfaces.

Full mesh HA, redundant interfaces and 802.3ad aggregate interfaces

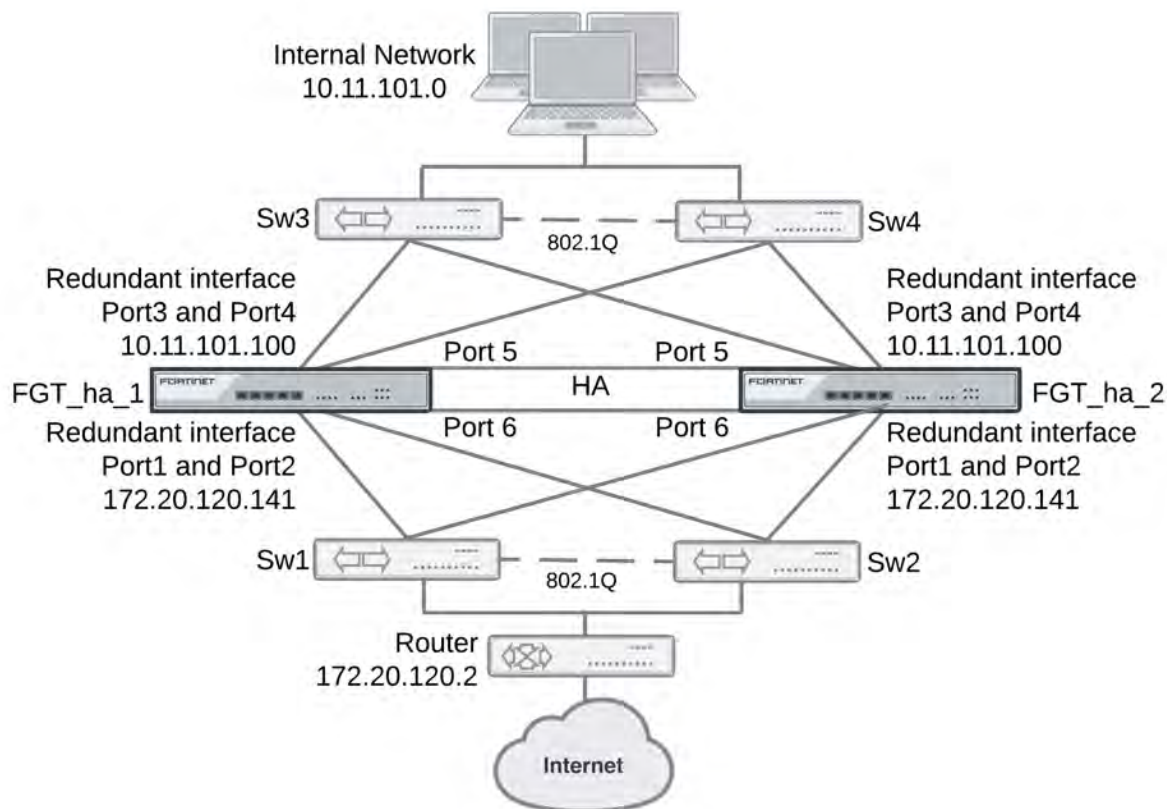

Full mesh HA is supported for both redundant interfaces and 802.3ad aggregate interfaces. In most cases you would simply use redundant interfaces. However, if your switches support 802.3ad aggregate interfaces and split multi-trunking you can use aggregate interfaces in place of redundant interfaces for full mesh HA. One advantage of using aggregate interfaces is that all of the physical interfaces in the aggregate interface can send and receive packets. As a result, using aggregate interfaces may increase the bandwidth capacity of the cluster.

Usually redundant and aggregate interfaces consist of two physical interfaces. However, you can add more than two physical interfaces to a redundant or aggregate interface. Adding more interfaces can increase redundancy protection. Adding more interfaces can also increase bandwidth capacity if you are using 802.3ad aggregate interfaces.

Example full mesh HA configuration

The following figure shows a full mesh HA configuration with a cluster of two FortiGate. This section describes the FortiGate configuration settings and network components required for a full mesh HA configuration. This section also contains example steps for setting up this full mesh HA configuration. The procedures in this section describe one of many possible sequences of steps for configuring full mesh HA. As you become more experienced with FortiOS, HA, and full mesh HA you may choose to use a different sequence of configuration steps.

Full Mesh HA configuration

For simplicity these procedures assume that you are starting with two new FortiGates set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

These procedures describe how to configure a cluster operating in NAT mode because NAT is the default FortiGate operating mode. However, the steps are the same if the cluster operates in transparent mode. You can either switch the cluster units to operate in transparent mode before beginning these procedures, or you can switch the cluster to operate in transparent mode after HA is configured and the cluster is connected and operating.

Full mesh HA configuration

The two FortiGates (FGT_ha_1 and FGT_ha_2) can be operating in NAT or transparent mode. Aside from the standard HA settings, the FortiGate configuration includes the following:

- The port5 and port6 interfaces configured as heartbeat interfaces. A full mesh HA configuration also includes redundant HA heartbeat interfaces.
- The port1 and port2 interfaces added to a redundant interface. Port1 is the active physical interface in this redundant interface. To make the port1 interface the active physical interface it should appear above the port2 interface in the redundant interface configuration.
- The port3 and port4 interfaces added to a redundant interface. Port3 is the active physical interface in this redundant interface. To make the port3 interface the active physical interface it should appear above the port4 interface in the redundant interface configuration.

Full mesh switch configuration

The following redundant switch configuration is required:

- Two redundant switches (Sw3 and Sw4) connected to the internal network. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.
- Two redundant switches (Sw1 and Sw2) connected to the Internet. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.

Full mesh network connections

Make the following physical network connections for FGT_ha_1:

- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

Make the following physical network connections for FGT_ha_2:

- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

How packets travel from the internal network through the full mesh cluster and to the Internet

If the cluster is operating in active-passive mode and FGT_ha_2 is the primary unit, all packets take the following path from the internal network to the internet:

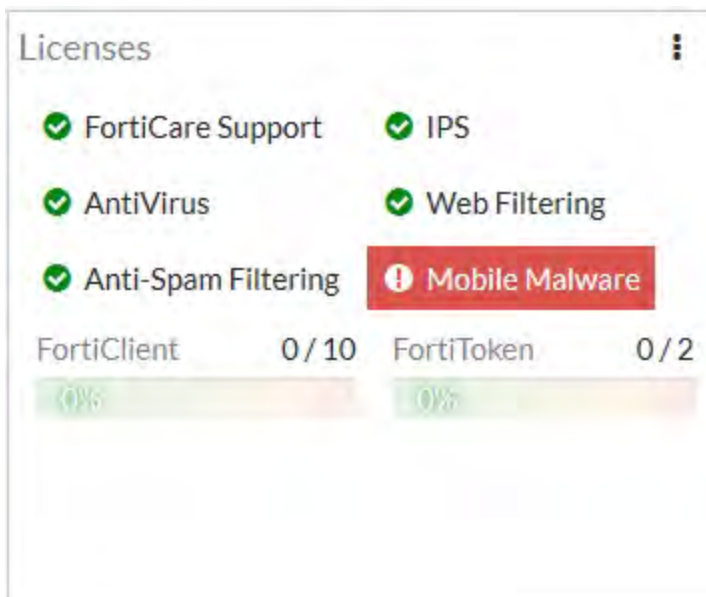

1. From the internal network to Sw4. Sw4 is the active connection to FGT_ha_2; which is the primary unit. The primary unit receives all packets.
2. From Sw4 to the FGT_ha_2 port3 interface. Active connection between Sw4 and FGT_ha_2. Port3 is the active member of the redundant interface.
3. From FGT_ha_2 port3 to FGT_ha_2 port1. Active connection between FGT_ha_2 and Sw2. Port1 is the active member of the redundant interface.
4. From Sw2 to the external router and the Internet.

Configuring full-mesh HA - GUI

Each cluster unit must have the same HA configuration.

To configure the FortiGate for HA operation

1. Register and apply licenses to the FortiGate.

2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate.

New Name	FGT_ha_1
-----------------	----------

4. Go to **System > HA** and change the following settings.

Mode	Active-Active	
Group Name	Rexample1.com	
Password	RHA_pass_1	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

5. Select **OK**.

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following

virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

6. Power off the first FortiGate.
7. Repeat these steps for the second FortiGate.

Set the second FortiGate host name to:

New Name	FGT_ha_2
----------	----------

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
 - Port1 to Sw1 (active)
 - Port2 to Sw2 (inactive)
 - Port3 to Sw3 (active)
 - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
 - Port1 to Sw2 (active)
 - Port2 to Sw1 (inactive)
 - Port3 to Sw4 (active)
 - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the **Cluster Name** (Rexample1.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
2. Go to **System > HA** to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGates are not functioning as a cluster. See [Example full mesh HA configuration on page 1862](#) to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster GUI.
2. Go to **System > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.

5. Select **OK**.
6. Go to **Network > Static Routes** and temporarily delete the default route.
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to **Network > Interfaces** and select **Create New > Interface** and configure the redundant interface to connect to the Internet.

Name	Port1_Port2
Type	Redundant
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

8. Select **OK**.
9. Select **Create New** and configure the redundant interface to connect to the internal network.

Name	Port3_Port4
Type	Redundant
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

10. Select **OK**.
The virtual MAC addresses of the FortiGate interfaces change to the following. Notice that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)

- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

11. Go to **Router > Static > Static Routes**.

12. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

13. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > HA**.
2. In the cluster members list, edit the primary unit.
3. Enable **interface monitoring** the **Port1_Port2** and the **Port3_Port4** interfaces
4. Select **OK**.

Configuring full mesh HA - CLI

Each cluster must have the same HA configuration. Use the following procedure to configure the FortiGates for HA operation.

To configure the FortiGates for HA operation

1. Register and apply licenses to the FortiGate.
2. Enter a new Host Name for this FortiGate.

```
config system global
    set hostname FGT_ha_1
end
```

3. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name Rexample1.com
    set password RHA_pass_1
    set hbdev port5 50 port6 50
end
```

The FortiGate negotiates to establish an HA cluster. When you select OK you may temporarily lose

connectivity with the FortiGate as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Power off the first FortiGate.
5. Repeat these steps for the second FortiGate.

Set the other FortiGate host name to:

```
config system global
  set hostname FGT_ha_2
end
```

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
 - Port1 to Sw1 (active)
 - Port2 to Sw2 (inactive)
 - Port3 to Sw3 (active)
 - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
 - Port1 to Sw2 (active)
 - Port2 to Sw1 (inactive)
 - Port3 to Sw4 (active)
 - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into.

If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit.

If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit.

If the command output includes `Current HA mode: standalone` the cluster unit is not operating in HA mode.

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
HA Health Status: OK
Model: FortiGate-XXXX
Mode: HA A-P
Group: 0
Debug: 0
Cluster Uptime: 7 days 00:30:26
.
.
.
```

You can use this command to confirm that the cluster is healthy and operating normally, some information about the cluster configuration, and information about how long the cluster has been

operating. Information not shown in this example includes how the primary unit was selected, configuration synchronization status, usage stats for each cluster unit, heartbeat status, and the relative priorities of the cluster units.

4. Use the `execute ha manage` command to connect to the other cluster unit's CLI and use these commands to verify cluster status.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGates are not functioning as a cluster. See [Example full mesh HA configuration on page 1862](#) to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings. Some steps use the CLI and some the GUI.

1. Log into the cluster CLI.
2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
  end
```

3. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

```
config router static
  delete 1
end
```

4. Go to **System > Network > Interface** and select **Create New** to add the redundant interface to connect to the Internet.
5. Add the redundant interface to connect to the Internet.

```
config system interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
  end
```

6. Add the redundant interface to connect to the internal network.

```
config system interface
  edit Port3_Port4
    set type redundant
    set member port3 port4
  end
```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01

- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

7. Go to Router > Static > Static Routes.

8. Add the default route.

```
config router static
edit 1
set dst 0.0.0.0 0.0.0.0
set gateway 172.20.120.2
set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1. Enter the following command to configure port monitoring for the redundant interfaces:

```
config system ha
set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting full mesh HA

Troubleshooting full mesh HA clusters is similar to troubleshooting any cluster (see [FGCP configuration examples and troubleshooting on page 1771](#) or [Virtual clusters on page 1850](#)). The configuration and operation of a full mesh HA cluster is very similar to the configuration and operation of a standard cluster. The only differences relate to the configuration, connection, and operation of the redundant interfaces and redundant switches.

- Make sure the redundant interfaces and switches are connected correctly. With so many connections it is possible to make mistakes or for cables to become disconnected.
- Confirm that the configuration of the cluster unit 802.3ad Aggregate or Redundant interfaces is correct according to the configuration procedures in this chapter.
- In some configurations with some switch hardware, MAC-learning delays on the inter-switch links on the surrounding topologies may occur. The delays occur if the gratuitous ARP packets sent by the cluster after a failover

are delayed by the switches before being sent across the inter-switch link. If this happens the surrounding topologies may be delayed in recognizing the failover and will keep sending packets to the MAC address of the failed primary unit resulting in lost traffic. Resolving this problem may require changing the configuration of the switch or replacing them with switch hardware that does not delay the gratuitous ARP packets.

Operating clusters and virtual clusters

With some exceptions, you can operate a cluster in much the same way as you operate a standalone FortiGate. This chapter describes those exceptions and also the similarities involved in operating a cluster instead of a standalone FortiGate.

Operating a cluster

The configurations of all of the FortiGates in a cluster are synchronized so that the cluster units can simulate a single FortiGate. Because of this synchronization, you manage the HA cluster instead of managing the individual cluster units. You manage the cluster by connecting to the GUI using any cluster interface configured for HTTPS or HTTP administrative access. You can also manage the cluster by connecting to the CLI using any cluster interface configured for SSH or telnet administrative access.

The cluster GUI dashboard displays the cluster name, the host name and serial number of each cluster member, and also shows the role of each unit in the cluster. The roles can be master (primary unit) and slave (subordinate units). The dashboard also displays a cluster unit front panel illustration.

You can also go to **System > HA** to view the cluster members list. This includes status information for each cluster unit. You can also use the cluster members list for a number of cluster management functions including changing the HA configuration of an operating cluster, changing the host name and device priority of a subordinate unit, and disconnecting a cluster unit from a cluster. See [Cluster members list on page 1892](#).

You can use log messages to view information about the status of the cluster. See [Clusters and logging on page 1884](#).

You can use SNMP to manage the cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration information and receive traps. See [Clusters and SNMP on page 1887](#).

You can configure a reserved management interface to manage individual cluster units. You can use this interface to access the GUI or CLI and to configure SNMP management for individual cluster units. See [Managing individual cluster units using a reserved out-of-band management interface on page 1875](#).

You can manage individual cluster units by using SSH, telnet, or the CLI console on the GUI dashboard to connect to the CLI of the cluster. From the CLI you can use the `execute ha manage` command to connect to the CLI of any unit in the cluster.

You can also manage individual cluster units by using a null-modem cable to connect to any cluster unit CLI. From there you can use the `execute ha manage` command to connect to the CLI of each unit in the cluster.

Operating a virtual cluster

Managing a virtual cluster is very similar to managing a cluster that does not contain multiple virtual domains. Most of the information in this chapter applies to managing both kinds of clusters. This section describes what is different when managing a virtual cluster.

If virtual domains are enabled, the cluster GUI dashboard displays the cluster name and the role of each cluster unit in virtual cluster 1 and virtual cluster 2.

The configuration and maintenance options that you have when you connect to a virtual cluster GUI or CLI depend on the virtual domain that you connect to and the administrator account that you use to connect.

If you connect to a cluster as the administrator of a virtual domain, you connect directly to the virtual domain. Since HA virtual clustering is a global configuration, virtual domain administrators cannot see HA configuration options. However, virtual domain administrators see the host name of the cluster unit that they are connecting to on the web browser title bar or CLI prompt. This host name is the host name of the primary unit for the virtual domain. Also, when viewing log messages the virtual domain administrator can select to view log messages for either of the cluster units.

If you connect to a virtual cluster as the admin administrator you connect to the global GUI or CLI. Even so, you are connecting to an interface and to the virtual domain that the interface has been added to. The virtual domain that you connect to does not make a difference for most configuration and maintenance operations. However, there are a few exceptions. You connect to the FortiGate that functions as the primary unit for the virtual domain. So the host name displayed on the web browser title bar and on the CLI is the host name of this primary unit.

Managing individual cluster units using a reserved out-of-band management interface

You can provide direct management access to all cluster units by reserving up to four management interfaces as part of the HA configuration. Once a management interface is reserved, you can configure a different IP address, administrative access and other interface settings for each management interface for each cluster unit. Then by connecting these interfaces of each cluster unit to your network you can manage each cluster unit separately from different IP addresses. Configuration changes to the reserved management interfaces are not synchronized to other cluster units.

You can also configure an in-band management interface for a cluster unit. See ["Managing individual cluster units using an in-band management IP address" on page 1881](#).

Reserved management interfaces provide direct management access to each cluster unit and give each cluster unit a different identity on your network. This simplifies using external services, such as SNMP, to separately monitor and manage each cluster unit.

The reserved management interfaces are not assigned HA virtual MAC addresses like other cluster interfaces. Instead the reserved management interfaces retain the permanent hardware address of the physical interface unless you change it using the `config system interface` command.

Reserved management interfaces and their IP addresses should not be used for managing a cluster using FortiManager. To correctly manage a FortiGate HA cluster with FortiManager use the IP address of one of the cluster unit interfaces.

If you enable SNMP administrative access for a reserved management interface you can use SNMP to monitor each cluster unit using the reserved management interface IP address. To monitor each cluster unit using SNMP, just add the IP address of each cluster unit's reserved management interface to the SNMP server configuration. You must also enable direct management of cluster members in the cluster SNMP configuration.

If you enable HTTPS or HTTP administrative access for the reserved management interfaces you can connect to the GUI of each cluster unit. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. From the subordinate units the GUI has the same features as the primary unit except that unit-specific information is displayed for the subordinate unit, for example:

- The **Dashboard System Information** widget displays the subordinate unit serial number but also displays the same information about the cluster as the primary unit

- On the Cluster members list (go to **System > HA**) you can change the HA configuration of the subordinate unit that you are logged into. For the primary unit and other subordinate units you can change only the host name and device priority.
- Log Access displays the logs of the subordinate that you are logged into first. You use the HA Cluster list to view the log messages of other cluster units including the primary unit.

If you enable SSH or TELNET administrative access for the reserved management interfaces you can connect to the CLI of each cluster unit. The CLI prompt contains the host name of the cluster unit that you have connected to. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. You can also use the `execute ha manage` command to connect to other cluster unit CLIs.

The reserved management interface is available in NAT and in transparent mode. It is also available if the cluster is operating with multiple VDOMs. In transparent mode you cannot normally add an IP address to an interface. However, you can add an IP address to the reserved management interface.

Reserved management interface for FortiSandbox, SNMP, and RADIUS

By default, management services such as SNMP, remote logging, remote authentication and so on use a cluster interface. As a result, communication from each cluster unit comes from a cluster interface instead of from the interface of an individual cluster unit and not from the HA reserved management interface.

If you want to use an HA reserved management interface for these management features you must enter the following command:

```
config system ha
    set ha-direct enable
end
```

By enabling `ha-direct`, the following management features will use the HA reserved management interface:

- Remote logging (including syslog, FortiAnalyzer, and FortiCloud).
- SNMP queries and traps.
- RADIUS remote authentication.
- Communication with FortiSandbox.

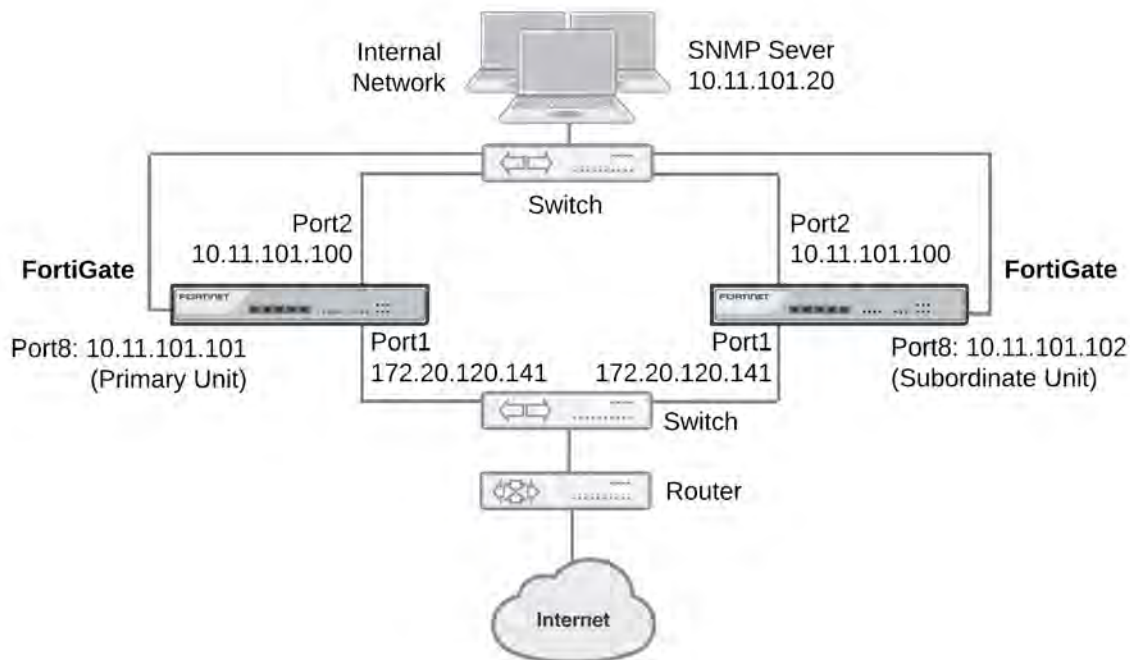

This means that individual cluster units send log messages and communicate with FortiSandbox and so on using their HA reserved management interface instead of one of the cluster interfaces. This allows you to manage each cluster unit separately and to separate the management traffic from each cluster unit. This can also be useful if each cluster unit is in a different location.

If you just want to use HA reserved management interfaces for SNMP remote management you can enable `ha-direct` in the SNMP configuration as shown in the following section.

Configuring the reserved management interface and SNMP remote management of individual cluster units

This example describes how to configure SNMP remote management of individual cluster units using an HA reserved management interface. The configuration consists of two FortiGate-620B units already operating as a cluster. In the example, the port8 interface of each cluster unit is connected to the internal network using the switch and configured as the reserved management interface.

SNMP remote management of individual cluster units

To configure the reserved management interface - GUI

From the GUI you can also configure IPv4 and IPv6 default routes that are only used by the reserved management interface.

1. Go to **System > HA**.
2. Edit the primary unit.
3. Select **Management Interface Reservation** and select port8.
4. Set **Gateway** to 10.11.101.2.
5. Set **IPv6 Gateway** to 2001:db8:0:2::20
6. Select **OK**.

To configure the reserved management interface - CLI

From the CLI you can also configure IPv4 and IPv6 default routes that are only used by the reserved management interface.

1. Log into the CLI of any cluster unit.
2. Enter the following command to enable the reserved management interface, set port8 as the reserved interface, and add an IPv4 default route of 10.11.101.2 and an IPv6 default route of 2001:db8:0:2::20 for the reserved management interface.

```
config system ha
  set ha-mgmt-status enable
  config ha-mgmt-interfaces
    edit 1
      set interface port8
```

```

set gateway 10.11.101.2
set gateway6 2001:db8:0:2::20
end

```

The reserved management interface default route is not synchronized to other cluster units.

To change the primary unit reserved management interface configuration - GUI

You can change the IP address of the primary unit reserved management interface from the primary unit GUI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. From a PC on the internal network, browse to <http://10.11.101.100> and log into the cluster GUI. This logs you into the primary unit GUI.

You can identify the primary unit from its serial number or host name that appears on the System Information dashboard widget.

2. Go to **Network > Interfaces** and edit the port8 interface as follows:

Alias	primary_reserved
IP/Netmask	10.11.101.101/24
Administrative Access	Ping, SSH, HTTPS, SNMP

3. Select **OK**.

You can now log into the primary unit GUI by browsing to <https://10.11.101.101>. You can also log into this primary unit CLI by using an SSH client to connect to 10.11.101.101.

To change subordinate unit reserved management interface configuration - CLI

At this point you cannot connect to the subordinate unit reserved management interface because it does not have an IP address. Instead, this procedure describes connecting to the primary unit CLI and using the `execute ha manage` command to connect to subordinate unit CLI to change the port8 interface. You can also use a serial connection to the cluster unit CLI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. Connect to the primary unit CLI and use the `execute ha manage` command to connect to a subordinate unit CLI. You can identify the subordinate unit from its serial number or host name. The host name appears in the CLI prompt.
2. Enter the following command to change the port8 IP address to 10.11.101.102 and set management access to HTTPS, ping, SSH, and SNMP.

```

config system interface
edit port8
set ip 10.11.101.102/24
set allowaccess https ping ssh snmp
end

```

You can now log into the subordinate unit GUI by browsing to <https://10.11.101.102>. You can also log into this subordinate unit CLI by using an SSH client to connect to 10.11.101.102.

To configure the cluster for SNMP management using the reserved management interfaces - CLI

This procedure describes how to configure the cluster to allow the SNMP server to get status information from the primary unit and the subordinate unit. The SNMP configuration is synchronized to all cluster units. To support using the reserved management interfaces, you must add at least one HA direct management host to an SNMP community. If your SNMP configuration includes SNMP users with user names and passwords you must also enable HA direct management for SNMP users.

1. Enter the following command to add an SNMP community called `Community` and add a host to the community for the reserved management interface of each cluster unit. The host includes the IP address of the SNMP server (10.11.101.20).

```
config system snmp community
edit 1
set name Community
config hosts
edit 1
set ha-direct enable
set ip 10.11.101.20
end
end
```

Enabling ha-direct in non-HA environments makes SNMP unusable.

- 2.
3. Enter the following command to add an SNMP user for the reserved management interface.

```
config system snmp user
edit 1
set ha-direct enable
set notify-hosts 10.11.101.20
end
```

Configure other settings as required.

To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses

From the command line of an SNMP manager, you can use the following SNMP commands to get CPU, memory and network usage information for each cluster unit. In the examples, the community name is `Community`. The commands use the MIB field names and OIDs listed below.

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.101 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.102 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Adding firewall local-in policies for the dedicated HA management interface

To add local-in policies for the dedicated management interface, enable `ha-mgmt-intf-only` and set `intf` to any. Enabling `ha-mgmt-intf-only` means the local-in policy applies only to the VDOM that contains the dedicated HA management interface. For example:

```
config firewall local-in-policy
edit 0
    set ha-mgmt-intf-only enable
    set intf any
    set scraddr internal-net
    set dstaddr mgmt-int
    set action accept
    set service HTTPS
    set schedule weekdays
end
```

NTP over Dedicated HA management interfaces

If you set up dedicated management interfaces on each cluster unit, if NTP is enabled, the primary unit contacts an NTP server using the dedicated management interface. System time is then synchronized to the backup units through the HA heartbeat.

Example CLI:

```
config system interface
edit port5
    set ip 172.16.79.46 255.255.255.0
end

config system ha
    set group-name FGT-HA
    set mode a-p
    set ha-mgmt-status enable
    config ha-mgmt-interfaces
        edit 1
            set interface port5
            set gateway 172.16.79.1
        end
    set ha-direct enable
end

config system ntp
    set ntpsync enable
    set syncinterval 5
```

```
end
```

Managing individual cluster units using an in-band management IP address

You can use the following command to add an in-band management IP address to an individual cluster unit interface that is also connected to a network and processing traffic. The in-band management IP address is an alternative to the reserved HA management interface feature and does not require reserving an interface just for management access.

```
config system interface
  edit port1
    set management-ip 172.20.121.155/24
  end
```

The management IP address is accessible from the network that the cluster interface is connected to. This setting is not synchronized so each cluster unit can have their own in-band management IP addresses. You can add a management IP address to one or more interfaces of each cluster unit.

The in-band management IP address should be on the same subnet as the interface you are adding it to, but cannot be on the same subnet as other interface IP addresses.

You can connect to the in-band management IP address using the interface's administrative access settings. The in-band management IP only supports the following subset of administrative access settings: ping, Telnet, HTTP, HTTPS, and SNMP.

For example, use the following command to add an in-band management IP address and allow access using HTTPS, SSH and SNMP:

```
config system interface
  edit port23
    set management-ip 172.25.12.5/24
    set allowaccess https ssh snmp
  end
```

Managing individual cluster units in a virtual cluster

You can select the HA option **Do NOT Synchronize Management VDOM Configuration** if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can select this option to prevent the management VDOM configuration from being synchronized between cluster units in a virtual cluster. This allows you to add an interface to the VDOM in each cluster unit and then to give the interfaces different IP addresses in each cluster unit, allowing you to manage each cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
  set standalone-mgmt-vdom enable
end
```

This feature must be disabled to manage a cluster using FortiManager.

Shutting down or rebooting the primary unit

You can shutdown or reboot the primary unit from the primary unit GUI by selecting **Shutdown** or **Reboot** from the **Admin** menu. From the primary unit CLI you can use the `execute reboot` or `execute shutdown` commands to shutdown or reboot the primary unit.

During the shutdown the primary unit first becomes the backup unit before shutting down allowing the backup unit to become the new primary unit and avoiding a split brain scenario. This behavior only happens when you manually shutdown or reboot the primary unit.

The primary unit acts as a router for subordinate unit management traffic

HA uses routing and inter-VDOM links to route subordinate unit management traffic through the primary unit to the network. Similar to a standalone FortiGate, subordinate units may generate their own management traffic, including:

- DNS queries.
- FortiGuard Web Filtering rating requests.
- Log messages to be sent to a FortiAnalyzer unit, to a syslog server, or to the FortiGuard Analysis and Management Service.
- Log file uploads to a FortiAnalyzer unit.
- Quarantine file uploads to a FortiAnalyzer unit.
- SNMP traps.
- Communication with remote authentication servers (RADIUS, LDAP, TACACS+ and so on)

Subordinate units send this management traffic over the HA heartbeat link to the primary unit. The primary unit forwards the management traffic to its destination. The primary unit also routes replies back to the subordinate unit in the same way.

HA uses a hidden VDOM called `vsys_ha` for HA operations. The `vsys_ha` VDOM includes the HA heartbeat interfaces, and all communication over the HA heartbeat link goes through the `vsys_ha` VDOM. To provide communication from a subordinate unit to the network, HA adds hidden inter-VDOM links between the primary unit management VDOM and the primary unit `vsys_ha` VDOM. By default, root is the management VDOM.

Management traffic from the subordinate unit originates in the subordinate unit `vsys_ha` VDOM. The `vsys_ha` VDOM routes the management traffic over the HA heartbeat link to the primary unit `vsys_ha` VDOM. This management traffic is then routed to the primary unit management VDOM and from there out onto the network.

DNS queries and FortiGuard Web Filtering and Email Filter requests are still handled by the HA proxy so the primary unit and subordinate units share the same DNS query cache and the same FortiGuard Web Filtering and Email Filter cache. In a virtual clustering configuration, the cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering, Email Filtering, and DNS query cache.

Subordinate unit management traffic path

Cluster communication with RADIUS and LDAP servers

In an active-passive cluster, only the primary unit processes traffic, so the primary unit communicates with RADIUS or LDAP servers. In a cluster that is operating in active-active mode, subordinate units send RADIUS and LDAP requests to the primary unit over the HA heartbeat link and the primary unit routes them to their destination. The primary unit relays the responses back to the subordinate unit.

Clusters and FortiGuard services

This section describes how various FortiGate HA clustering configurations communicate with the FDN.

In an operating cluster, the primary unit communicates directly with the FortiGuard Distribution Network (FDN). Subordinate units also communicate directly with the FDN but as described above, all communication between subordinate units and the FDN is routed through the primary unit.

You must register and license all of the units in a cluster for all required FortiGuard services, both because all cluster units communicate with the FDN and because any cluster unit could potentially become the primary unit.

FortiGuard and active-passive clusters

For an active-passive cluster, only the primary unit processes traffic. Even so, all cluster units communicate with the FDN. Only the primary unit sends FortiGuard Web Filtering and Antispam requests to the FDN. All cluster units receive FortiGuard Antivirus, IPS, and application control updates from the FDN.

In an active-passive cluster the FortiGuard Web Filter and Email Filter caches are located on the primary unit in the same way as for a standalone FortiGate. The caches are not shared among cluster units so after a failover the new primary unit must build up new caches.

In an active-passive cluster all cluster units also communicate with the FortiGuard Analysis and Management Service (FAMS).

FortiGuard and active-active clusters

For an active-active cluster, both the primary unit and the subordinate units process traffic. Communication between the cluster units and the FDN is the same as for active-passive clusters with the following exception.

Because the subordinate units process traffic, they may also be making FortiGuard Web Filtering and Email Filter requests. The primary unit receives all such requests from the subordinate units and relays them to the FDN and then relays the FDN responses back to the subordinate units. The FortiGuard Web Filtering and Email Filtering

URL caches are maintained on the primary unit. The primary unit caches are used for primary and subordinate unit requests.

FortiGuard and virtual clustering

For a virtual clustering configuration the management virtual domain of each cluster unit communicates with the FDN. The cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering and Email Filtering caches. All FortiGuard Web Filtering and Email Filtering requests are proxied by the management VDOM of the cluster unit that is the primary unit for the management virtual domain.

Clusters and logging

This section describes the log messages that provide information about how HA is functioning, how to view and manage logs for each unit in a cluster, and provides some example log messages that are recorded during specific cluster events.

You configure logging for a cluster in the same way as you configuring logging for a standalone FortiGate. Log configuration changes made to the cluster are synchronized to all cluster units.

All cluster units record log messages separately to the individual cluster unit's log disk, to the cluster unit's system memory, or both. You can view and manage log messages for each cluster unit from the cluster GUI Log Access page.

When remote logging is configured, all cluster units send log messages to remote FortiAnalyzer units or other remote servers as configured. HA uses routing and inter-VDOM links to route subordinate unit log traffic through the primary unit to the network.

When you configure a FortiAnalyzer unit to receive log messages from a FortiGate cluster, you should add a cluster to the FortiAnalyzer unit configuration so that the FortiAnalyzer unit can receive log messages from all cluster units.

Viewing and managing log messages for individual cluster units

This section describes how to view and manage log messages for an individual cluster unit.

To view HA cluster log messages

1. Log into the cluster GUI.
2. Go to **Log&Report > Log Config > Log Settings > GUI Preferences** and select to display logs from **Memory, Disk or FortiAnalyzer**.

For each log display, the **HA Cluster** list displays the serial number of the cluster unit for which log messages are displayed. The serial numbers are displayed in order in the list.

3. Set **HA Cluster** to the serial number of one of the cluster units to display log messages for that unit.

About HA event log messages

HA event log messages always include the host name and serial number of the cluster unit that recorded the message. HA event log messages also include the HA state of the unit and also indicate when a cluster unit switches (or moves) from one HA state to another. Cluster units can operate in the HA states listed below:

HA states

Hello	A FortiGate configured for HA operation has started up and is looking for other FortiGates with which to form a cluster.
Work	In an active-passive cluster a cluster unit is operating as the primary unit. In an active-active cluster unit is operating as the primary unit or a subordinate unit.
Standby	In an active-passive cluster the cluster unit is operating as a subordinate unit.

HA log Event log messages also indicate the virtual cluster that the cluster unit is operating in as well as the member number of the unit in the cluster. If virtual domains are not enabled, all clusters unit are always operating in virtual cluster 1. If virtual domains are enabled, a cluster unit may be operating in virtual cluster 1 or virtual cluster 2. The member number indicates the position of the cluster unit in the cluster members list. Member 0 is the primary unit. Member 1 is the first subordinate unit, member 2 is the second subordinate unit, and so on.

HA log messages

See the FortiOS log message reference for a listing of and descriptions of the HA log messages.

FortiGate HA message "HA master heartbeat interface <intf_name> lost neighbor information"

The following HA log messages may be recorded by an operating cluster:

```
2009-02-16 11:06:34 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=critical vd=root msg="HA slave heartbeat interface internal lost neighbor information"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=notice vd=root msg="Virtual cluster 1 of group 0 detected new joined HA member"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha
pri=notice vd=root msg="HA master heartbeat interface internal get peer information"
```

These log messages indicate that the cluster units could not connect to each other over the HA heartbeat link for the period of time that is given by hb-interval x hb-lost-threshold, which is 1.2 seconds with the default values.

To diagnose this problem

1. Check all heartbeat interface connections including cables and switches to make sure they are connected and operating normally.
2. Use the following commands to display the status of the heartbeat interfaces.

```
get hardware nic <heartbeat_interface_name>
diagnose hardware deviceinfo nic <heartbeat_interface_name>
```

The status information may indicate the interface status and link status and also indicate if a large number of errors have been detected.

3. If the log message only appears during peak traffic times, increase the tolerance for missed HA heartbeat packets by using the following commands to increase the lost heartbeat threshold and heartbeat interval:

```
config system ha
    set hb-lost-threshold 12
    set hb-interval 4
end
```

These settings multiply by 4 the loss detection interval. You can use higher values as well.

This condition can also occur if the cluster units are located in different buildings or even different geographical locations. Called a distributed cluster, as a result of the separation it may take a relatively long time for heartbeat packets to be transmitted between cluster units. You can support a distributed cluster by increasing the heartbeat interval so that the cluster expects extra time between heartbeat packets.

4. Optionally disable session-pickup to reduce the processing load on the heartbeat interfaces.
5. Instead of disabling session-pickup you can enable `session-pickup-delay` to reduce the number of sessions that are synchronized. With this option enabled only sessions that are active for more than 30 seconds are synchronized.

It may be useful to monitor CPU and memory usage to check for low memory and high CPU usage. You can configure event logging to monitor CPU and memory usage. You can also enable the CPU over usage and memory low SNMP events.

Once this monitoring is in place, try and determine if there have been any changes in the network or an increase of traffic recently that could be the cause. Check to see if the problem happens frequently and if so what the pattern is.

To monitor the CPU of the cluster units and troubleshoot further, use the following procedure and commands:

```
get system performance status
get system performance top 2
diagnose sys top 2
```

These commands repeated at frequent intervals will show the activity of the CPU and the number of sessions.

Search the Fortinet Knowledge Base for articles about monitoring CPU and Memory usage.

If the problem persists, gather the following information (a console connection might be necessary if connectivity is lost) and provide it to Technical Support when opening a ticket:

- Debug log from the GUI: **System > Advanced > Download Debug Log**
- CLI command output:

```
diagnose sys top 2 (keep it running for 20 seconds)
get system performance status (repeat this command multiple times to get good samples)
get system ha status
diagnose sys ha status
diagnose sys ha dump-by {all options}
diagnose netlink device list
diagnose hardware deviceinfo nic <heartbeat-interface-name>
execute log filter category 1
execute log display
```

Formatting cluster unit hard disks (log disks)

If you need to format the hard disk (also called log disk or disk storage) of one or more cluster units you should disconnect the unit from the cluster and use the `execute formatlogdisk` command to format the cluster unit hard disk then add the unit back to the cluster.

For information about how to remove a unit from a cluster and add it back, see [Disconnecting a cluster unit from a cluster on page 1905](#) and [Adding a disconnected FortiGate back to its cluster on page 1906](#).

Once you add the cluster unit with the formatted log disk back to the cluster you should make it the primary unit before removing other units from the cluster to format their log disks and then add them back to the cluster.

Clusters and SNMP

You can use SNMP to manage a cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration and status information and receive traps.

You configure SNMP for a cluster in the same way as configuring SNMP for a standalone FortiGate. SNMP configuration changes made to the cluster are shared by all cluster units.

Each cluster unit sends its own traps and SNMP manager systems can use SNMP get commands to query each cluster unit separately. To set SNMP get queries to each cluster unit you must create a special get command that includes the serial number of the cluster unit.

Alternatively you can use the HA reserved management interface feature to give each cluster unit a different management IP address. Then you can create an SNMP get command for each cluster unit that just includes the management IP address and does not have to include the serial number.

SNMP get command syntax for the primary unit

Normally, to get configuration and status information for a standalone FortiGate or for a primary unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to the following:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

<address_ipv4> is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. The HA MIB fields and OIDs are listed below:

SNMP field names and OIDs

MIB field	OID	Description
fgHaSystemMode	.1.3.6.1.4.1.12356.101.13.1.1.0	HA mode (standalone, a-a, or a-p)
fgHaGroupId	.1.3.6.1.4.1.12356.101.13.1.2.0	The HA group ID of the cluster unit.
fgHaPriority	.1.3.6.1.4.1.12356.101.13.1.3.0	The HA priority of the cluster unit. Default 128.
fgHaOverride	.1.3.6.1.4.1.12356.101.13.1.4.0	Whether HA override is disabled or enabled for the cluster unit.
fgHaAutoSync	.1.3.6.1.4.1.12356.101.13.1.5.0	Whether automatic HA synchronization is disabled or enabled.

MIB field	OID	Description
fgHaSchedule	.1.3.6.1.4.1.12356.101.13.1.6.0	The HA load balancing schedule. Set to none unless operating in a-p mode.
fgHaGroupName	.1.3.6.1.4.1.12356.101.13.1.7.0	The HA group name.
fgHaStatsIndex	.1.3.6.1.4.1.12356.101.13.2.1.1.1.1	An index value that identifies the FortiGates in an HA cluster. The index is always 1 for the FortiGate that receives the HA get. The other FortiGate(s) in the cluster will have an index of 2, 3, or 4. For example, if you get the stats index from the primary FortiGate, the primary FortiGate will have a stats index of 1 and the backup FortiGate will have a stats index of 2. If you get the stats index from the backup unit, the backup unit will have a stats index of 1 and the primary unit will have a stats index of 2.
fgHaStatsSerial	.1.3.6.1.4.1.12356.101.13.2.1.1.2.1	The serial number of the cluster unit.
fgHaStatsCpuUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.3.1	The cluster unit's current CPU usage.
fgHaStatsMemUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.4.1	The cluster unit's current Memory usage.
fgHaStatsNetUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.5.1	The cluster unit's current Network bandwidth usage.
fgHaStatsSesCount	.1.3.6.1.4.1.12356.101.13.2.1.1.6.1	The cluster unit's current session count.
fgHaStatsPktCount	.1.3.6.1.4.1.12356.101.13.2.1.1.7.1	The cluster unit's current packet count.
fgHaStatsByteCount	.1.3.6.1.4.1.12356.101.13.2.1.1.8.1	The cluster unit's current byte count.
fgHaStatsIdsCount	.1.3.6.1.4.1.12356.101.13.2.1.1.9.1	The number of attacks reported by the IPS for the cluster unit.
fgHaStatsAvCount	.1.3.6.1.4.1.12356.101.13.2.1.1.10.1	The number of viruses reported by the antivirus system for the cluster unit.
fgHaStatsHostname	.1.3.6.1.4.1.12356.101.13.2.1.1.11.1	The hostname of the cluster unit.

To get the HA priority for the primary unit

The following SNMP get command gets the HA priority for the primary unit. The community name is `public`. The IP address of the cluster interface configured for SNMP management access is `10.10.10.1`. The HA priority MIB field is `fgHaPriority` and the OID for this MIB field is `1.3.6.1.4.1.12356.101.13.1.3.0`. The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgHaPriority
```

```
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.1.3.0
```

SNMP get command syntax for any cluster unit

To get configuration status information for a specific cluster unit (for the primary unit or for any subordinate unit), the SNMP manager must add the serial number of the cluster unit to the SNMP get command after the community name. The community name and the serial number are separated with a dash. The syntax for this SNMP get command would be:

```
snmpget -v2c -c <community_name>-<fgt_serial> <address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. All units in the cluster have the same community name. The most commonly used community name is `public`.

<fgt_serial> is the serial number of any cluster unit. For example, FGT4002803033172. You can specify the serial number of any cluster unit, including the primary unit, to get information for that unit.

<address_ipv4> is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself.

If the serial number matches the serial number of a subordinate unit, the SNMP get request is sent over the HA heartbeat link to the subordinate unit. After processing the request, the subordinate unit sends the reply back over the HA heartbeat link back to the primary unit. The primary unit then forwards the response back to the SNMP manager.

If the serial number matches the serial number of the primary unit, the SNMP get request is processed by the primary unit. You can actually add a serial number to the community name of any SNMP get request. But normally you only need to do this for getting information from a subordinate unit.

To get the CPU usage for a subordinate unit

The following SNMP get command gets the CPU usage for a subordinate unit in a FortiGate-5001SX cluster. The subordinate unit has serial number FG50012205400050. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1. The HA status table MIB field is `fgHaStatsCpuUsage` and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.3.1. The first command uses the MIB field name and the second uses the OID for this table:

```
snmpget -v2c -c public-FG50012205400050 10.10.10.1 fgHaStatsCpuUsage
snmpget -v2c -c public-FG50012205400050 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
```

FortiGate SNMP recognizes the community name with syntax `<community_name>-<fgt_serial>`. When the primary unit receives an SNMP get request that includes the community name followed by serial number, the FGCP extracts the serial number from the request. Then the primary unit redirects the SNMP get request to the cluster unit with that serial number. If the serial number matches the serial number of the primary unit, the SNMP get is processed by the primary unit.

Getting serial numbers of cluster units

The following SNMP get commands use the MIB field name `fgHaStatsSerial.<index>` to get the serial number of each cluster unit. Where `<index>` is the cluster unit's cluster index and 1 is the cluster index of the primary unit, 2 is the cluster index of the first subordinate unit, and 3 is the cluster index of the second subordinate unit.

The OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.2.1. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1.

The first command uses the MIB field name and the second uses the OID for this table and gets the serial number of the primary unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.1
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.2.1
```

The second command uses the MIB field name and the second uses the OID for this table and gets the serial number of the first subordinate unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.2
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.2.2
```

SNMP get command syntax - reserved management interface enabled

To get configuration and status information for any cluster unit where you have enabled the HA reserved management interface feature and assigned IP addresses to the management interface of each cluster unit, an SNMP manager would use the following get command syntax:

```
snmpget -v2c -c <community_name> <mgmt_address_ipv4> {<OID> | <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community names to a FortiGate SNMP configuration. The most commonly used community name is public.

<mgmt_address_ipv4> is the IP address of the FortiGate HA reserved management interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see your FortiGate's online help.

Adding FortiClient licenses to a cluster

Each FortiGate in a cluster must have its own FortiClient license. Contact your reseller to purchase FortiClient licenses for all of the FortiGates in your cluster.

When you receive the license keys you can visit the [Fortinet Support](#) website and add the FortiClient license keys to each FortiGate. Then, as long as the cluster can connect to the Internet each cluster unit receives its FortiClient license key from the FortiGuard network.

Adding FortiClient licenses to cluster units with a reserved management interface

You can also use the following steps to manually add license keys to your cluster units from the GUI or CLI. Your cluster must be connected to the Internet and you must have configured a reserved management interface for each cluster unit.

1. Log into the GUI of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside **FortiClient** select **Enter License**.
3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the reserved management IP address to log into each cluster unit CLI and use following command to add the license key:

```
execute FortiClient-NAC update-registration-license <license-key>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

Adding FortiClient licenses to cluster units with no reserved management interface

If you have not set up reserved management IP addresses for your cluster units, you can still add FortiClient license keys to each cluster unit. You must log into the primary unit and then use the `execute ha manage` command to connect to each cluster unit CLI. For example, use the following steps to add a FortiClient license key a cluster of three FortiGates:

1. Log into the primary unit CLI and enter the following command to confirm the serial number of the primary unit:

```
get system status
```

2. Add the FortiClient license key for that serial number to the primary unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

You can also use the GUI to add the license key to the primary unit.

3. Enter the following command to log into the first subordinate unit:

```
execute ha manage 1
```

4. Enter the following command to confirm the serial number of the cluster unit that you have logged into:

```
get system status
```

5. Add the FortiClient license key for that serial number to the cluster unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

6. Enter the following command to log into the second subordinate unit:

```
execute ha manage 2
```

7. Enter the following command to confirm the serial number of the cluster unit that you have logged into:

```
get system status
```

8. Add the FortiClient license key for that serial number to the cluster unit:

```
execute FortiClient-NAC update-registration-license <license-key>
```

Viewing FortiClient license status and active FortiClient users for each cluster unit

To view FortiClient license status and FortiClient information for each cluster unit you must log into each cluster unit's GUI or CLI. You can do this by connecting to each cluster unit's reserved management interface if they are configured. If you have not configured reserved management interfaces you can use the `execute ha manage` command to log into each cluster unit CLI.

From the GUI, view FortiClient License status from the License Information dashboard widget and select **Details** to display the list of active FortiClient users connecting through that cluster unit. You can also see active FortiClient users by going to **User & Device > Monitor > FortiClient**.

From the CLI you can use the `execute FortiClient {list | info}` command to display FortiClient license status and active FortiClient users.

For example, use the following command to display the FortiClient license status of the cluster unit that you are logged into:

```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
  NAC: 114
  WANOPT: 0
  Test: 0
```

Other connections:

IPsec: 0

SSLVPN: 0

Use the following command to display the list of active FortiClient users connecting through the cluster unit. The output shows the time the connection was established, the type of FortiClient connection, the name of the device, the user name of the person connecting, the FortiClient ID, the host operating system, and the source IP address of the session.

```
execute forticlient list
TIMESTAMP TYPE CONNECT-NAME USER CLIENT-ID HOST-OS SRC-IP

Cluster members list

To display the cluster members list, log into an operating cluster and go to **System > HA**.

The cluster members list displays illustrations of the front panels of the cluster units. The displays use color coding to indicate the status and configuration of individual cluster unit interfaces:

- Green indicates data interfaces that are up and connected to data networks
- Yellow indicates monitored data interfaces that are up and connected to data networks
- Red indicates connected heartbeat interfaces
- Grey indicates unconnected data interfaces
- A pale salmon color indicates disconnected monitored interfaces or heartbeat interfaces

You can hover the mouse pointer over each interface to view the interface IP address (if any) link status, and speed.

From the cluster members list you can:

- View HA statistics including uptime, sessions, and throughput for each cluster unit.
- Click and drag to change the order of the cluster units.
- See the host name of each cluster unit. To change the primary unit host name, go to **System > Settings** and change the **Host Name**. To view and change a subordinate unit host name, edit the subordinate unit from the cluster members list.
- View the status or role of each cluster unit (master or slave).
- View and optionally change the HA configuration of the operating cluster.
- Disconnect a device from the cluster.

Virtual cluster members list

If virtual domains are enabled, you can display the cluster members list to view the status of the operating virtual clusters. The virtual cluster members list shows the status of both virtual clusters including the virtual domains added to each virtual cluster.

To display the virtual cluster members list for an operating cluster log in as the admin administrator, select Global Configuration and go to **System > HA**.

The functions of the virtual cluster members list are the same as the functions of the Cluster Members list with the following exceptions.

- When you edit a primary unit in a virtual cluster, you can change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit and you can edit the VDOM partitioning configuration of the cluster.
- When you edit a subordinate unit in a virtual cluster, you can change the device priority for the subordinate unit for the selected virtual cluster.

Also, the HA cluster members list changes depending on the cluster unit that you connect to.

Viewing HA statistics

From the cluster members list you can select **View HA statistics** to display the serial number, status, and monitor information for each cluster unit. To view HA statistics, go to **System > HA** and select View HA Statistics. Note the following about the HA statistics display:

- Use the serial number ID to identify each FortiGate in the cluster. The cluster ID matches the FortiGate serial number.
- Status indicates the status of each cluster unit. A green check mark indicates that the cluster unit is operating normally. A red X indicates that the cluster unit cannot communicate with the primary unit.
- The up time is the time in days, hours, minutes, and seconds since the cluster unit was last started.
- The GUI displays CPU usage for core processes only. CPU usage for management processes (for example, for HTTPS connections to the GUI) is excluded.
- The GUI displays memory usage for core processes only. Memory usage for management processes (for example, for HTTPS connections to the GUI) is excluded.

Changing the HA configuration of an operating cluster

To change the configuration settings of an operating cluster, go to **System > HA** to display the cluster members list. Select Edit for the master (or primary) unit in the cluster members list to display the HA configuration page for the cluster.

You can use the HA configuration page to check and fine tune the configuration of the cluster after the cluster is up and running. For example, if you connect or disconnect cluster interfaces you may want to change the Port Monitor configuration.

Any changes you make on this page, with the exception of changes to the device priority, are first made to the primary unit configuration and then synchronized to the subordinate units. Changing the device priority only affects the primary unit.

Changing the HA configuration of an operating virtual cluster

To change the configuration settings of the primary unit in a functioning cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > HA** to display the cluster members list. Select Edit for the master (or primary) unit in virtual cluster 1 or virtual cluster 2 to display the HA configuration page for the virtual cluster.

You can use the virtual cluster HA configuration page to check and fine tune the configuration of both virtual clusters after the cluster is up and running. For example, you may want to change the Port Monitor configuration for virtual cluster 1 and virtual cluster 2 so that each virtual cluster monitors its own interfaces.

You can also use this configuration page to move virtual domains between virtual cluster 1 and virtual cluster 2. Usually you would distribute virtual domains between the two virtual clusters to balance the amount of traffic being processed by each virtual cluster.

Any changes you make on this page, with the exception of changes to the device priorities, are first made to the primary unit configuration and then synchronized to the subordinate unit.

You can also adjust device priorities to configure the role of this cluster unit in the virtual cluster. For example, to distribute traffic to both cluster units in the virtual cluster configuration, you would want one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. You can create this configuration by setting the device priorities. The cluster unit with the highest device priority in virtual cluster 1 becomes the primary unit for virtual cluster 1. The cluster unit with the highest device priority in virtual cluster 2 becomes the primary unit in virtual cluster 2.

Changing the subordinate unit host name and device priority

To change the host name and device priority of a subordinate unit in an operating cluster, go to **System > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

To change the host name and device priority of a subordinate unit in an operating cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

You can change the host name (Peer) and device priority (Priority) of this subordinate unit. These changes only affect the configuration of the subordinate unit.

The device priority is not synchronized among cluster members. In a functioning cluster you can change device priority to change the priority of any unit in the cluster. The next time the cluster negotiates, the cluster unit with the highest device priority becomes the primary unit.

The device priority range is 0 to 255. The default device priority is 128.

Upgrading cluster firmware

You can upgrade the FortiOS firmware running on an HA cluster in the same manner as upgrading the firmware running on a standalone FortiGate. During a normal firmware upgrade, the cluster upgrades the primary unit and all subordinate units to run the new firmware image. The firmware upgrade takes place without interrupting communication through the cluster.

Upgrading cluster firmware to a new major release (for example upgrading from 5.6.3 to 6.0.2) is supported for clusters. Make sure you are taking an appropriate [upgrade path](#). Even so you should back up your configuration and only perform such a firmware upgrade during a maintenance window.

To upgrade the firmware without interrupting communication through the cluster, the cluster goes through a series of steps that involve first upgrading the firmware running on the subordinate units, then making one of the subordinate units the primary unit, and finally upgrading the firmware on the former primary unit. These steps are transparent to the user and the network, but depending upon your HA configuration may result in the cluster selecting a new primary unit.

The following sequence describes in detail the steps the cluster goes through during a firmware upgrade and how different HA configuration settings may affect the outcome.

1. The administrator uploads a new firmware image from the GUI or CLI.
2. If the cluster is operating in active-active mode load balancing is turned off.
3. The cluster upgrades the firmware running on all of the subordinate units.
4. Once the subordinate units have been upgraded, a new primary unit is selected.
This primary unit will be running the new upgraded firmware.
5. The cluster now upgrades the firmware of the former primary unit.
If the age of the new primary unit is more than 300 seconds (5 minutes) greater than the age of all other cluster units, the new primary unit continues to operate as the primary unit.

This is the intended behavior but does not usually occur because the age difference of the cluster units is usually less than the cluster age difference margin of 300 seconds. So instead, the cluster negotiates again to select a primary unit as described in [Primary unit selection on page 1744](#).

You can keep the cluster from negotiating again by reducing the cluster age difference margin using the `ha-uptime-diff-margin` option. However, you should be cautious when reducing the age or other problems may occur. For information about the cluster age difference margin, see [Cluster age difference margin \(grace period\) on page 1747](#). For more information about changing the cluster age margin, see [Changing the cluster age difference margin on page 1748](#).

6. If the cluster is operating in active-active mode, load balancing is turned back on.

If, during the firmware upgrade process all of the subordinate units crash or otherwise stop responding, the primary unit will not be upgraded to the new firmware, but will continue to operate normally. The primary unit waits until at least one subordinate unit rejoins the cluster before upgrading its firmware.

Changing how the cluster processes firmware upgrades

By default cluster firmware upgrades proceed as uninterruptible upgrades that do not interrupt traffic flow. If required, you can use the following CLI command to change how the cluster handles firmware upgrades. You might want to change this setting if you are finding uninterruptible upgrades take too much time.

```
config system ha
    set uninterruptible-upgrade disable
end
```

`uninterruptible-upgrade` is enabled by default. If you disable `uninterruptible-upgrade` the cluster still upgrades the firmware on all cluster units, but all cluster units are upgraded at once; which takes less time but interrupts communication through the cluster.

Synchronizing the firmware build running on a new cluster unit

If the firmware build running on a FortiGate that you add to a cluster is older than the cluster firmware build, you may be able to use the following steps to synchronize the firmware running on the new cluster unit.

This procedure describes re-installing the same firmware build on a cluster to force the cluster to upgrade all cluster units to the same firmware build.

Due to firmware upgrade and synchronization issues, in some cases this procedure may not work. In all cases it will work to install the same firmware build on the new unit as the one that the cluster is running before adding the new unit to the cluster.

To synchronize the firmware build running on a new cluster unit

1. Obtain a firmware image that is the same as build already running on the cluster.
2. Connect to the cluster using the GUI.
3. Go to the **System Information** dashboard widget.
4. Select **Update** beside **Firmware Version**.
You can also install a newer firmware build.
5. Select **OK**.
After the firmware image is uploaded to the cluster, the primary unit upgrades all cluster units to this firmware build.

Downgrading cluster firmware

For various reasons you may need to downgrade the firmware that a cluster is running. You can use the information in this section to downgrade the firmware version running on a cluster.

In most cases you can downgrade the firmware on an operating cluster using the same steps as for a firmware upgrade. A warning message appears during the downgrade but the downgrade usually works and after the downgrade the cluster continues operating normally with the older firmware image.

Downgrading between some firmware versions, especially if features have changed between the two versions, may not always work without the requirement to fix configuration issues after the downgrade.

Only perform firmware downgrades during maintenance windows and make sure you back up your cluster configuration before the downgrade.

If the firmware downgrade that you are planning may not work without configuration loss or other problems, you can use the following downgrade procedure to make sure your configuration is not lost after the downgrade.

To downgrade cluster firmware

This example shows how to downgrade the cluster shown in Example NAT mode HA network topology. The cluster consists of two cluster units (FGT_ha_1 and FGT_ha_2). The port1 and port2 interfaces are connected to networks and the port3 and port4 interfaces are connected together for the HA heartbeat.

This example, describes separating each unit from the cluster and downgrading the firmware for the standalone FortiGates. There are several ways you could disconnect units from the cluster. This example describes using the disconnect from cluster function on the cluster members list GUI page.

1. Go to the **System Information** dashboard widget and backup the cluster configuration.
From the CLI use `execute backup config`.
2. Go to **System > HA** and for FGT_ha_1 select the **Disconnect from cluster** icon.
3. Select the port2 interface and enter an IP address and netmask of 10.11.101.101/24 and select **OK**.
From the CLI you can enter the following command (FG600B3908600705 is the serial number of the cluster unit) to be able to manage the standalone FortiGate by connecting to the port2 interface with IP address and netmask 10.11.101.101/24.

```
execute ha disconnect FG600B3908600705 port2 10.11.101.101/24
```

After FGT_ha_1 is disconnected, FGT_ha_2 continues processing traffic.

4. Connect to the FGT_ha_1 GUI or CLI using IP address 10.11.101.101/24 and follow normal procedures to downgrade standalone FortiGate firmware.

5. When the downgrade is complete confirm that the configuration of FGT_ha_1 is correct.
6. Set the HA mode of FGT_ha_2 to Standalone and follow normal procedures to downgrade standalone FortiGate firmware.
Network communication will be interrupted for a short time during the downgrade.
7. When the downgrade is complete confirm that the configuration of FGT_ha_2 is correct.
8. Set the HA mode of FGT_ha_2 to Active-Passive or the required HA mode.
9. Set the HA mode of FGT_ha_1 to the same mode as FGT_ha_2.
If you have not otherwise changed the HA settings of the cluster units and if the firmware downgrades have not affected the configurations the units should negotiate and form cluster running the downgraded firmware.

Backing up and restoring the cluster configuration

You can backup and restore the configuration of a cluster in the same way as backing up and restoring a standalone FortiGate unit. Backing up the cluster from the primary unit GUI or CLI saves a single configuration file for the cluster. If you restore this configuration file, the configuration of all cluster units is restored. The restore process keeps configuration settings of individual cluster units that are not synchronized unchanged but resets all other configuration setting to those in the restored configuration file.

When restoring the configuration of a cluster, all cluster units reboot to install the new configuration. This may result in a brief traffic interruption as all cluster units may restart at the same time.

Restoring settings that are not synchronized

The FGCP does not synchronize some FortiOS configuration settings. For details about settings that are not synchronized, see [Synchronizing the configuration \(and settings that are not synchronized\) on page 1735](#). If you need to restore the configuration of the cluster including the configuration settings that are not synchronized, you should first restore the configuration of the primary FortiGate and then restore the configuration of the other cluster units. Alternatively you could log into each FortiGate in the cluster and manually add the configuration settings that were not restored.

Monitoring cluster units for failover

If the primary unit in the cluster fails, the units in the cluster renegotiate to select a new primary unit. Failure of the primary unit results in the following:

- If SNMP is enabled, the new primary unit sends HA trap messages. The messages indicate a cluster status change, HA heartbeat failure, and HA member down.
- If event logging is enabled and HA activity event is selected, the new primary unit records log messages that show that the unit has become the primary unit.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGates. The failed primary unit no longer appears on the Cluster Members list.
- The host name and serial number of the primary unit changes. You can see these changes when you log into the GUI or CLI.

- The cluster info displayed on the dashboard, cluster members list or from the `get system ha status` command changes.

If a subordinate unit fails, the cluster continues to function normally. Failure of a subordinate unit results in the following:

- If event logging is enabled and HA activity event is selected, the primary unit records log messages that show that a subordinate has been removed from the cluster.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGates. The failed unit no longer appears on the Cluster Members list.

Viewing cluster status from the CLI

Use the `get system ha status` command to display information about an HA cluster. The command displays general HA configuration settings. The command also displays information about how the cluster unit that you have logged into is operating in the cluster. You can enter the `get system ha status` command from the primary or backup units. The output produced by the command is similar for each unit, it shows cluster data as well as data for the FortiGate that you are logged into.

For a virtual cluster configuration, the `get system ha status` command displays information about how the cluster unit that you have logged into is operating in virtual cluster 1 and virtual cluster 2. For example, if you connect to the cluster unit that is the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2, the output of the `get system ha status` command shows virtual cluster 1 in the work state and virtual cluster 2 in the standby state. The `get system ha status` command also displays additional information about virtual cluster 1 and virtual cluster 2.

The command includes the following fields.

Field	Description
HA Health Status	Indicates if all cluster units are operating normally (OK) or if a problem was detected with the cluster. For example, a message similar to <code>ERROR <serial-number> is lost @ <date> <time></code> appears if one the subordinate units leaves the cluster.
Model	The FortiGate model number.
Mode	The HA mode of the cluster, for example, HA A-P or HA A-A.
Group	The group ID of the cluster.
Debug	The debug status of the cluster.
Cluster Uptime	The number of days, hours, minutes, and seconds that the cluster has been operating.
Cluster state changed time	The date and time at which the FortiGate most recently changed state. For example, the last time the FortiGate joined the cluster or changed from the primary unit to a backup unit, and so on.

Field	Description
Master selected using	Shows how the primary unit was selected the last four times that the cluster negotiated. For example, when a cluster first forms, this part of the command output could have one line showing that the primary unit is the cluster unit with the highest uptime. Up to four lines can be included as the cluster negotiates to choose a new primary unit on different occasions. Each line includes a time stamp and the criteria used to select the primary unit.
ses_pickup	The status of session pickup: enable or disable.
load_balance	The status of the <code>load-balance-all</code> keyword: enable or disable. Active-active clusters only.
load_balance_udp	The status of the <code>load-balance-udp</code> keyword: enable or disable. Available on some FortiGate models. Active-active clusters only.
schedule	The active-active load balancing schedule. Active-active clusters only.
override	The status of the override option for the current cluster unit: enable or disable.
Configuration Status	Shows if the configurations of each of the cluster units are synchronized or not.
System Usage stats	Shows how busy each cluster unit is by displaying the number of sessions being processed by the cluster unit, CPU usage, and memory usage.
HBDEV stats	Shows the status of each cluster unit's heartbeat interfaces. Includes whether the interfaces are up or down, how much data they have processed, as well as errors found.
Master Slave	<p>Displays the host name, serial number, and cluster index of the primary unit (master) and the subordinate units (slave). The FortiGate with cluster index 0 is the primary unit and the FortiGates with cluster indexes 1 to 3 are the backup units.</p> <p>The order in which the cluster units are listed starts with the cluster unit that you are logged into.</p>
number of vcluster	The number of virtual clusters. If virtual domains are not enabled, the cluster has one virtual cluster. If virtual domains are enabled the cluster has two virtual clusters.
vcluster 1 vcluster 2	The heartbeat interface IP address of the primary unit in each virtual cluster. If virtual domains are not enabled there is one vcluster and this is the IP address of the primary unit. If virtual domains are enabled then each vcluster line will have an IP address. If the IP addresses are the same then the same FortiGate is the primary unit for both virtual clusters.

Field	Description
<code>vcluster 1</code>	<p>The HA state (hello, work, or standby) and HA heartbeat IP address of the primary unit. If virtual domains are not enabled, <code>vcluster 1</code> displays information for the cluster. If virtual domains are enabled, <code>vcluster 1</code> displays information for virtual cluster 1.</p>
Master	<p><code>vcluster 1</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 1. The list includes the serial number and operating cluster index of each cluster unit in virtual cluster 1. The cluster unit that you have logged into is at the top of the list. The FortiGate in the cluster with the highest serial number always has an operating cluster index of 0. Other FortiGates in the cluster get a higher operating cluster index based in their serial number. When you use the <code>execute ha manage</code> command to log into another FortiGate you use the operating cluster index to specify the FortiGate to log into.</p>
Slave	<p>If virtual domains are not enabled and you connect to the primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the primary unit.</p> <p>If virtual domains are not enabled and you connect to a subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you have logged into.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the virtual cluster 1 primary unit.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>
<code>vcluster 2</code>	<p><code>vcluster 2</code> only appears if virtual domains are enabled. <code>vcluster 2</code> displays the HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 2. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 2 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 2.</p>
Master	<p><code>vcluster 2</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 2. The list includes the cluster index and serial number of each cluster unit in virtual cluster 2. The cluster unit that you have logged into is at the top of the list.</p>
Slave	<p>If you connect to the virtual cluster 2 primary unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>work</code>. The display lists the cluster units starting with the virtual cluster 2 primary unit.</p> <p>If you connect to the virtual cluster 2 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>standby</code>. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>

Get system ha status example - two FortiGates in active-passive mode

The following example shows `get system ha status` output for a cluster of two FortiGate-600Ds operating in active-passive mode. The cluster is healthy and has been running for 3 hours and 26 minutes. Primary unit selection took place once and the cluster has been stable since then.

The following command output was produced by connecting to the primary unit CLI (host name Edge2-Primary).

```
get system ha status
HA Health Status: OK
Model: FortiGate-600D
Mode: HA A-P
Group: 25
Debug: 0
Cluster Uptime: 0 days 03:26:00
Cluster state change time: 2018-03-06 13:16:33
Master selected using:
    <2018/03/06 13:16:33> FGT6HD3916806098 is selected as the master because it has the
largest value of override priority.
    <2018/03/06 12:47:58> FGT6HD3916806070 is selected as the master because it has the
largest value of override priority.
    <2018/03/06 12:47:55> FGT6HD3916806098 is selected as the master because it has the
largest value of uptime.
    <2018/03/06 12:47:55> FGT6HD3916806098 is selected as the master because it's the only
member in the cluster.

```

About the HA operating cluster index and the execute ha manage command

When a cluster starts up, if primary unit select is based on serial number, the FortiGate Cluster Protocol (FGCP) assigns a cluster index and an HA heartbeat IP address to each cluster unit based on the serial number of the cluster unit:

- The FGCP selects the cluster unit with the highest serial number to become the primary unit. The FGCP assigns a cluster index of 0, an operating cluster index of 0, and an HA heartbeat IP address of 169.254.0.1 to this unit.

- The FGCP assigns a cluster index of 1, an operating cluster index of 1, and an HA heartbeat IP address of 169.254.0.2 to the cluster unit with the second highest serial number.
- If the cluster contains more units, the cluster unit with the third highest serial number is assigned a cluster index of 2, and operating cluster index of 2, and an HA heartbeat IP address of 169.254.0.3, and so on.

You can display the cluster index and operating cluster index assigned to each cluster unit using the `get system ha status` command. When you use the `execute ha manage` command you select a cluster unit to log into by entering its operating cluster index.

The operating cluster index and HA heartbeat IP address only change if a unit leaves the cluster or if a new unit joins the cluster. When one of these events happens, the FGCP resets the cluster index, operating cluster index, and HA heartbeat IP address of each cluster unit according to serial number in the same way as when the cluster first starts up.

If FortiGates don't leave or join, each cluster unit keeps its assigned operating cluster index, and HA heartbeat IP address since these are based on the FortiGate serial number, even as the units take on different roles in the cluster. After the operating cluster index and HA heartbeat IP addresses are set according to serial number, the FGCP checks other primary unit selection criteria such as device priority and monitored interfaces. Checking these criteria could result in selecting a cluster unit without the highest serial number to operate as the primary unit.

Even if the cluster unit without the highest serial number now becomes the primary unit, the operating cluster indexes and HA heartbeat IP addresses assigned to the individual cluster units do not change. Instead the FGCP changes the cluster index to reflect this role change. The cluster index is always 0 for the primary unit and 1 and higher for the other units in the cluster. By default both sets of cluster indexes are the same. But if primary unit selection selects the cluster unit that does not have the highest serial number to be the primary unit, then this cluster unit is assigned a cluster index of 0.

Using the `execute ha manage` command

When you use the CLI command `execute ha manage <index_integer>` to connect to the CLI of another cluster unit, the `<index_integer>` that you enter is the operating cluster index of the unit that you want to connect to.

Using `get system ha status` to display cluster indexes

You can display the cluster index assigned to each cluster unit using the CLI command `get system ha status`. The following example shows the information displayed by the `get system ha status` command for a cluster consisting of two FortiGates operating in active-passive HA mode with virtual domains not enabled and without virtual clustering.

```
get system ha status
.
.
.
Master: Edge2-Primary , FGT6HD3916806098, cluster index = 0
Slave : Edge2-Backup , FGT6HD3916806070, cluster index = 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master: FGT6HD3916806098, operating cluster index = 0
Slave : FGT6HD3916806070, operating cluster index = 1
```

In this example, the cluster unit with serial number FGT6HD3916806098 has the highest serial number and so has a cluster index and an operating cluster index of 0 and the cluster unit with serial number

FGT6HD3916806070 has a cluster index and an operating cluster index of 1. From the CLI of the primary unit of this cluster you can connect to the CLI of the subordinate unit using the following command:

```
execute ha manage 1
```

This works because the cluster unit with serial number FGT6HD3916806070 has a cluster index of 1.

The last three lines of the command output display the status of vcluster 1. In a cluster consisting of two cluster units operating without virtual domains enabled, all clustering actually takes place in virtual cluster 1. HA is designed to work this way to support virtual clustering. If this cluster was operating with virtual domains enabled, adding virtual cluster 2 is similar to adding a new copy of virtual cluster 1. Virtual cluster 2 is visible in the `get system ha status` command output when you add virtual domains to virtual cluster 2.

The HA heartbeat IP address displayed by the command is the HA heartbeat IP address of the cluster unit that is actually operating as the primary unit. For a default configuration, this IP address will always be 169.254.0.1 because the cluster unit with the highest serial number will be the primary unit. This IP address changes if the operating primary unit is not the primary unit with the highest serial number.

Example where the cluster index and operating cluster index do not match

This example shows `get system ha status` command output for the same cluster. However, in this example the device priority of the cluster unit with the serial number FGT6HD3916806098 is increased to 250. As a result the cluster unit with the lowest serial number becomes the primary unit. This means the cluster index and the operating cluster index of the cluster units do not match.

```
get system ha status
.
.
.
Master: Edge2-Primary , FGT6HD3916806098, cluster index = 1
Slave : Edge2-Backup , FGT6HD3916806070, cluster index = 0
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master: FGT6HD3916806098, operating cluster index = 0
Slave : FGT6HD3916806070, operating cluster index = 1
```

The actual cluster indexes have not changed but the operating cluster indexes have. Also, the HA heartbeat IP address displayed for vcluster 1 has changed to 169.254.0.2.

Virtual clustering example output

The `get system ha status` command output is the same if a cluster is operating with virtual clustering turned on but with all virtual domains in virtual cluster 1. The following `get system ha status` command output example shows the same cluster operating as a virtual cluster with virtual domains in virtual cluster 1 and added to virtual cluster 2. In this example the cluster unit with serial number FG50012204400045 is the primary unit for virtual cluster 1 and the cluster unit with serial number FG50012205400050 is the primary unit for virtual cluster 2.

```
get system ha status
.
.
.
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master: FG50012205400050, operating cluster index = 1
Slave : FG50012204400045, operating cluster index = 0
vcluster 2: standby 169.254.0.1
```

```
Master: FG50012205400050, operating cluster index = 0
```

```
Slave : FG50012204400045, operating cluster index = 1
```

This example shows three sets of indexes. The indexes in lines six and seven are still used by the `execute ha manage` command. The indexes on lines ten and eleven are for the primary and subordinate units in virtual cluster 1 and the indexes on the last two lines are for virtual cluster 2.

Managing individual cluster units

The following procedure describes how to use SSH to log into the primary unit CLI and from there to use the `execute ha manage` command to connect to the CLI of any other unit in the cluster. The procedure is very similar if you use telnet, or the GUI dashboard CLI console.

You can use the `execute ha manage` command from the CLI of any cluster unit to log into the CLI of another the cluster unit. Usually you would use this command from the CLI of the primary unit to log into the CLI of a subordinate unit. However, if you have logged into a subordinate unit CLI, you can use this command to log into the primary unit CLI, or the CLI of another subordinate unit.

Using SSH or telnet or the GUI CLI console you can only log into the primary unit CLI. Using a direct console connection you can log into any cluster unit. In both cases you can use `execute ha manage` to connect to the CLI of other cluster units.

1. Log into the primary unit CLI.

Connect to any cluster interface configured for SSH administrative access to log into the cluster.

2. Enter the following command followed by a space and type a question mark (?):

```
execute ha manage
```

The CLI displays a list of the serial numbers of all of the subordinate units in the cluster. Each cluster unit is numbered. The number is the operating cluster index.

3. Complete the command with the operating cluster index number of the subordinate unit to log into. For example, to log into subordinate unit 1, enter the following command:

```
execute ha manage 1
```

4. Log into the CLI of the selected subordinate unit.

The CLI prompt changes to the host name of the subordinate unit. You can use CLI commands to manage this subordinate unit. If you make changes to the configuration of any cluster unit (primary or subordinate unit) these changes are synchronized to all cluster units.

5. You can now use the `execute ha manage` command to connect to any other cluster unit (including the primary unit). You can also use the `exit` command to return to the primary unit CLI.

Disconnecting a cluster unit from a cluster

Use the following procedures to disconnect a cluster unit from a functioning cluster without disrupting the operation of the cluster. You can disconnect a cluster unit if you need to use the disconnected FortiGate for another purpose, such as to act as a standalone firewall.

You can use the following procedures for a standard cluster and for a virtual clustering configuration. To use the following procedures from a virtual cluster you must be logged in as the admin administrator and you must have selected Global Configuration.

When you disconnect a cluster unit you must assign an IP address and netmask to one of the interfaces of the disconnected unit. You can disconnect any unit from the cluster even the primary unit. After the unit is

disconnected, the cluster responds as if the disconnected unit has failed. The cluster may renegotiate and may select a new primary unit.

When the cluster unit is disconnected the HA mode is changed to standalone. In addition, all interface IP addresses of the disconnected unit are set to 0.0.0.0 except for the interface that you configure.

Otherwise the configuration of the disconnected unit is not changed. The HA configuration of the disconnected unit is not changed either (except to change the HA mode to Standalone).

To disconnect a cluster unit from a cluster - GUI

1. Go to **System > HA** to view the cluster members list.
2. Select the Disconnect from cluster icon for the cluster unit to disconnect from the cluster.
3. Select the interface that you want to configure. You also specify the IP address and netmask for this interface. When the FortiGate is disconnected, all management access options are enabled for this interface.
4. Specify an IP address and netmask for the interface. You can use this IP address to connect to the interface to configure the disconnected FortiGate.
5. Select **OK**.

The FortiGate is disconnected from the cluster and the cluster may renegotiate and select a new primary unit. The selected interface of the disconnected unit is configured with the specified IP address and netmask.

To disconnect a cluster unit from a cluster - CLI

1. Enter the following command to disconnect a cluster unit with serial number FGT5002803033050. The internal interface of the disconnected unit is set to IP address 1.1.1.1 and netmask 255.255.255.0.

```
execute ha disconnect FGT5002803033050 internal 1.1.1.1 255.255.255.0
```

Adding a disconnected FortiGate back to its cluster

If you disconnect a FortiGate from a cluster, you can re-connect the disconnected FortiGate to the cluster by setting the HA mode of the disconnected unit to match the HA mode of the cluster. Usually the disconnected unit rejoins the cluster as a subordinate unit and the cluster automatically synchronizes its configuration.

You do not have to change the HA password on the disconnected unit unless the HA password has been changed after the unit was disconnected. Disconnecting a unit from a cluster does not change the HA password.

You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. You should also make sure that the HA `override` CLI option is not enabled on the disconnected unit. Otherwise, when the disconnected unit joins the cluster, the cluster will renegotiate and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units. This configuration change might disrupt the operation of the cluster.

The following procedure assumes that the disconnected FortiGate is correctly physically connected to your network and to the cluster but is not running in HA mode and not part of the cluster.

Before you start this procedure you should note the device priority of the primary unit.

To add a disconnected FortiGate back to its cluster - GUI

1. Log into the disconnected FortiGate.
If virtual domains are enabled, log in as the admin administrator and select Global Configuration.
2. Go to **System > HA**.
3. Change Mode to match the mode of the cluster.
4. If required, change the group name and password to match the cluster.
5. Set the Device Priority lower than the device priority of the primary unit.
6. Select **OK**.
The disconnected FortiGate joins the cluster.

To add a disconnected FortiGate back to its cluster - CLI

1. Log into the CLI of the FortiGate to be added back to the cluster.
2. Enter the following command to access the global configuration and add the FortiGate back to a cluster operating in active-passive mode and set the device priority to 50 (a low number) so that this unit will not become the primary unit:

```
config global
  config system ha
    set mode a-p
    set priority 50
  end
end
```

You may have to also change the group name, group id and password. However if you have not changed these for the cluster or the FortiGate after it was disconnected from the cluster you should not have to adjust them now.

diagnose sys ha dump-by command

You can use the following diagnose command to display a data about a cluster:

```
diagnose sys ha dump-by {group | vcluster | rcache | debug-zone | vdom | kernel | device |
  stat | sesync}
```

kernel

This command displays the HA configuration stored by the kernel.

```
diagnose sys ha dump-by kernel
  HA information.
group_id=88, nvcluster=2, mode=2, load_balance=0, schedule=3, ldb_udp=0.
nvcluster=2, mode=2, ses_pickup=0, delay=0, load_balance=0
schedule=3, ldb_udp=0, standalone_ha=0, upgrade_mode=0.
vcluster 1:
FGT51E5618000206, 0, 0.
FGT51E5618000259, 1, 1.
vcluster 2:
FGT51E5618000206, 1, 1.
FGT51E5618000259, 0, 0.
```

stat

This command displays some statistics about how well the cluster is functioning. Information includes packet counts, memory use, failed links and ping failures.

```
diagnose sys ha dump-by stat
HA information.
packet count = 1, memory = 220.
check_linkfails = 0, linkfails = 0, check_pingsvrfails = 2822
bufcnt = -5, bufmem = 0
```

HA and failover protection

In FortiGate active-passive HA, the FortiGate Clustering Protocol (FGCP) provides failover protection. This means that an active-passive cluster can provide FortiGate services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiGate. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially in a mission-critical environment.

The FGCP supports three kinds of failover protection. Device failover automatically replaces a failed device and restarts traffic flow with minimal impact on the network. Link failover maintains traffic flow if a link fails. Session failover resumes communication sessions with minimal loss of data if a device or link failover occurs.

This chapter describes how FGCP failover protection works and provides detailed NAT and transparent mode packet flow descriptions.

About active-passive failover

To achieve failover protection in an active-passive cluster, one of the cluster units functions as the primary unit, while the rest of the cluster units are subordinate units, operating in an active stand-by mode. The cluster IP addresses and HA virtual MAC addresses are associated with the cluster interfaces of the primary unit. All traffic directed at the cluster is actually sent to and processed by the primary unit.

While the cluster is functioning, the primary unit functions as the FortiGate network security device for the networks that it is connected to. In addition, the primary unit and subordinate units use the HA heartbeat to keep in constant communication. The subordinate units report their status to the cluster unit and receive and store connection and state table updates.

Device failure

If the primary unit encounters a problem that is severe enough to cause it to fail, the remaining cluster units negotiate to select a new primary unit. This occurs because all of the subordinate units are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves.

Using the same FGCP negotiation process that occurs when the cluster starts up, after they determine that the primary unit has failed, the subordinate units negotiate amongst themselves to select a new primary unit. The subordinate unit that wins the negotiation becomes the new primary unit with the same MAC and IP addresses as the former primary unit. The new primary unit then sends gratuitous ARP packets out all of its interfaces to inform attached switches to send traffic to the new primary unit. Sessions then resume with the new primary unit.

Link failure

If a primary unit interface fails or is disconnected while a cluster is operation, a link failure occurs. When a link failure occurs the cluster units negotiate to select a new primary unit. Since the primary unit has not stopped operating, it participates in the negotiation. The link failure means that a new primary unit must be selected and the cluster unit with the link failure joins the cluster as a subordinate unit.

Just as for a device failover, the new primary unit sends gratuitous arp packets out all of its interfaces to inform attached switches to send traffic to it. Sessions then resume with the new primary unit.

If a subordinate unit experiences a device failure its status in the cluster does not change. However, in future negotiations a cluster unit with a link failure is unlikely to become the primary unit.

Session failover

If you enable session failover (also called session pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed.

Primary unit recovery

If a primary unit recovers after a device or link failure, it will operate as a subordinate unit, unless the `override` CLI keyword is enabled and its device priority is set higher than the unit priority of other cluster units (see [HA override on page 1752](#)).

About active-active failover

HA failover in a cluster running in active-active mode is similar to active-passive failover described above. Active-active subordinate units are constantly waiting to negotiate to become primary units and, if session failover is enabled, continuously receive connection state information from the primary unit. If the primary unit fails, or one of the primary unit interfaces fails, the cluster units use the same mechanisms to detect the failure and to negotiate to select a new primary unit. If session failover is enabled, the new primary unit also maintains communication sessions through the cluster using the shared connection state table.

Active-active HA load balances sessions among all cluster units. For session failover, the cluster must maintain all of these sessions. To load balance sessions, the functioning cluster uses a load balancing schedule to distribute sessions to all cluster units. The shared connection state table tracks the communication sessions being processed by all cluster units (not just the primary unit). After a failover, the new primary unit uses the load balancing schedule to re-distribute all of the communication sessions recorded in the shared connection state table among all of the remaining cluster units. The connections continue to be processed by the cluster, but possibly by a different cluster unit, and are handled according to their last known state.

Device failover

The FGCP provides transparent device failover. Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

In the case of FortiOS HA, the device is the primary unit. If the primary unit fails, device failover ensures that one of the subordinate units in the cluster automatically takes the place of the primary unit and can continue processing network traffic in the same way as the failed primary unit.

Device failover does not maintain communication sessions. After a device failover, communication sessions have to be restarted. To maintain communication sessions, you must enable session failover. See [Device failover on page 1910](#).

FortiGate HA device failover is supported by the HA heartbeat, virtual MAC addresses, configuration synchronization, route synchronization and IPsec VPN SA synchronization.

The HA heartbeat makes sure that the subordinate units detect a primary unit failure. If the primary unit fails to respond on time to HA heartbeat packets the subordinate units assume that the primary unit has failed and negotiate to select a new primary unit.

The new primary unit takes the place of the failed primary unit and continues functioning in the same way as the failed primary unit. For the new primary unit to continue functioning like the failed primary unit, the new primary unit must be able to reconnect to network devices and the new primary unit must have the same configuration as the failed primary unit.

FortiGate HA uses virtual MAC addresses to reconnect the new primary unit to network devices. The FGCP causes the new primary unit interfaces to acquire the same virtual MAC addresses as the failed primary unit. As a result, the new primary unit has the same network identity as the failed primary unit.

The new primary unit interfaces have different physical connections than the failed primary unit. Both the failed and the new primary unit interfaces are connected to the same switches, but the new primary unit interfaces are connected to different ports on these switches. To make sure that the switches send packets to the new primary unit, the new primary unit interfaces send gratuitous ARP packets to the connected switches. These gratuitous ARP packets notify the switches that the primary unit MAC and IP addresses are on different switch ports and cause the switches to send packets to the ports connected to the new primary unit. In this way, the new primary unit continues to receive packets that would otherwise have been sent to the failed primary unit.

Configuration synchronization means that the new primary unit always has the same configuration as the failed primary unit. As a result the new primary unit operates in exactly the same way as the failed primary unit. If configuration synchronization were not available the new primary unit may not process network traffic in the same way as the failed primary unit.

Kernel routing table synchronization synchronizes the primary unit kernel routing table to all subordinate units so that after a failover the new primary unit does not have to form a completely new routing table. IPsec VPN SA synchronization synchronizes IPsec VPN security associations (SAs) and other IPsec session data so that after a failover the new primary unit can resume IPsec tunnels without having to establish new SAs.

HA heartbeat and communication between cluster units

The HA heartbeat keeps cluster units communicating with each other. The heartbeat consists of hello packets that are sent at regular intervals by the heartbeat interface of all cluster units. These hello packets describe the state of the cluster unit and are used by other cluster units to keep all cluster units synchronized.

HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8893. The default time interval between HA heartbeats is 200 ms. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

For best results, isolate the heartbeat devices from your user networks by connecting the heartbeat devices to a separate switch that is not connected to any network. If the cluster consists of two FortiGates you can connect the heartbeat device interfaces directly using a crossover cable. Heartbeat packets contain sensitive information

about the cluster configuration. Heartbeat packets may also use a considerable amount of network bandwidth. For these reasons, it is preferable to isolate heartbeat packets from your user networks.

On startup, a FortiGate configured for HA operation broadcasts HA heartbeat hello packets from its HA heartbeat interface to find other FortiGates configured to operate in HA mode. If two or more FortiGates operating in HA mode connect with each other, they compare HA configurations (HA mode, HA password, and HA group ID). If the HA configurations match, the units negotiate to form a cluster.

While the cluster is operating, the HA heartbeat confirms that all cluster units are functioning normally. The heartbeat also reports the state of all cluster units, including the communication sessions that they are processing.

Heartbeat interfaces

A heartbeat interface is an Ethernet network interface in a cluster that is used by the FGCP for HA heartbeat communications between cluster units.

To change the HA heartbeat configuration go to **System > HA** and select the *FortiGate interfaces* to use as HA heartbeat interfaces.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

From the CLI enter the following command to make port4 and port5 HA heartbeat interfaces and give both interfaces a heartbeat priority of 150:

```
config system ha
    set hbdev port4 150 port5 150
end
```

The following example shows how to change the default heartbeat interface configuration so that the port4 and port1 interfaces can be used for HA heartbeat communication and to give the port4 interface the highest heartbeat priority so that port4 is the preferred HA heartbeat interface.

```
config system ha
    set hbdev port4 100 port1 50
end
```

By default, for most FortiGate models two interfaces are configured to be heartbeat interfaces. You can change the heartbeat interface configuration as required. For example you can select additional or different heartbeat interfaces. You can also select only one heartbeat interface.

In addition to selecting the heartbeat interfaces, you also set the **Priority** for each heartbeat interface. In all cases, the heartbeat interface with the highest priority is used for all HA heartbeat communication. If the interface fails or becomes disconnected, the selected heartbeat interface that has the next highest priority handles all heartbeat communication.

If more than one heartbeat interface has the same priority, the heartbeat interface with the highest priority that is also highest in the heartbeat interface list is used for all HA heartbeat communication. If this interface fails or becomes disconnected, the selected heartbeat interface with the highest priority that is next highest in the list handles all heartbeat communication.

The default heartbeat interface configuration sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration if one or both of the default heartbeat interfaces are connected. You can select different heartbeat interfaces, select more heartbeat interfaces and change heartbeat priorities according to your requirements.

For the HA cluster to function correctly, you must select at least one heartbeat interface and this interface of all of the cluster units must be connected together. If heartbeat communication is interrupted and cannot failover to a second heartbeat interface, the cluster units will not be able to communicate with each other and more than one cluster unit may become a primary unit. As a result the cluster stops functioning normally because multiple devices on the network may be operating as primary units with the same IP and MAC addresses creating a kind of split brain scenario.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. The higher the number the higher the priority.

In most cases you can maintain the default heartbeat interface configuration as long as you can connect the heartbeat interfaces together. Configuring HA heartbeat interfaces is the same for virtual clustering and for standard HA clustering.

You can enable heartbeat communications for physical interfaces, but not for VLAN subinterfaces, IPsec VPN interfaces, redundant interfaces, or for 802.3ad aggregate interfaces. You cannot select these types of interfaces in the heartbeat interface list.

Selecting more heartbeat interfaces increases reliability. If a heartbeat interface fails or is disconnected, the HA heartbeat fails over to the next heartbeat interface.

You can select up to 8 heartbeat interfaces. This limit only applies to FortiGates with more than 8 physical interfaces.

HA heartbeat traffic can use a considerable amount of network bandwidth. If possible, enable HA heartbeat traffic on interfaces used only for HA heartbeat traffic or on interfaces connected to less busy networks.

Connecting HA heartbeat interfaces

For most FortiGate models if you do not change the heartbeat interface configuration, you can isolate the default heartbeat interfaces of all of the cluster units by connecting them all to the same switch. Use one switch per heartbeat interface. If the cluster consists of two units you can connect the heartbeat interfaces together using crossover cables.

HA heartbeat and data traffic are supported on the same cluster interface. In NAT mode, if you decide to use heartbeat interfaces for processing network traffic or for a management connection, you can assign the interface any IP address. This IP address does not affect HA heartbeat traffic.

In transparent mode, you can connect the heartbeat interface to your network and enable management access. You would then establish a management connection to the interface using the transparent mode management IP address. This configuration does not affect HA heartbeat traffic.

Heartbeat packets and heartbeat interface selection

HA heartbeat hello packets are constantly sent by all of the enabled heartbeat interfaces. Using these hello packets, each cluster unit confirms that the other cluster units are still operating. The FGCP selects one of the heartbeat interfaces to be used for communication between the cluster units. The FGCP selects the heartbeat interface for heartbeat communication based on the linkfail states of the heartbeat interfaces, on the priority of the heartbeat interfaces, and on the interface index.

The FGCP checks the linkfail state of all heartbeat interfaces to determine which ones are connected. The FGCP selects one of these connected heartbeat interfaces to be the one used for heartbeat communication. The FGCP selects the connected heartbeat interface with the highest priority for heartbeat communication.

If more than one connected heartbeat interface has the highest priority the FGCP selects the heartbeat interface with the lowest interface index. The GUI lists the FortiGate interfaces in alphabetical order. This order corresponds to the interface index order with lowest index at the top and highest at the bottom. If more than one heartbeat interface has the highest priority, the FGCP selects the interface that is highest in the heartbeat interface list (or first in alphabetical order) for heartbeat communication.

If the interface that is processing heartbeat traffic fails or becomes disconnected, the FGCP uses the same criteria to select another heartbeat interface for heartbeat communication. If the original heartbeat interface is fixed or reconnected, the FGCP again selects this interface for heartbeat communication.

The HA heartbeat communicates cluster session information, synchronizes the cluster configuration, synchronizes the cluster kernel routing table, and reports individual cluster member status. The HA heartbeat constantly communicates HA status information to make sure that the cluster is operating properly.

Interface index and display order

The GUI and CLI display interface names in alphanumeric order. For example, the sort order for a FortiGate with 10 interfaces (named port1 through port10) places port10 at the bottom of the list:

- port1
- port2 through 9
- port10

However, interfaces are indexed in hash map order, rather than purely by alphabetic order or purely by interface number value comparisons. As a result, the list is sorted primarily alphabetical by interface name (for example, base1 is before port1), then secondarily by index numbers:

- port1
- port10
- port2 through port9

HA heartbeat interface IP addresses

The FGCP uses link-local IPv4 addresses ([RFC 3927](#)) in the 169.254.0.x range for HA heartbeat interface IP addresses and for inter-VDOM link interface IP addresses. When a cluster initially starts up, the primary unit heartbeat interface IP address is 169.254.0.1. Subordinate units are assigned heartbeat interface IP addresses in the range 169.254.0.2 to 169.254.0.63. HA inter-VDOM link interfaces on the primary unit are assigned IP addresses 169.254.0.65 and 169.254.0.66.

If a failover occurs, the primary unit heartbeat interface could be something other than 169.254.0.1. If for example, the first subordinate unit is now the primary unit, the primary unit heartbeat interface IP address would be 169.254.0.2.

The output from the `get system ha status` CLI command shows the HA heartbeat interface IP address of the primary unit.

```
get system ha status
.
.
.
vcluster 1: work 169.254.0.2
.
.
.
```

You can also use the `execute traceroute` command from the subordinate unit CLI to display HA heartbeat IP addresses and the HA inter-VDOM link IP addresses. For example, use `execute ha manage 1` to connect to the subordinate unit CLI and then enter the following command to trace the route to an IP address on your network:

```
execute traceroute 172.20.20.10
traceroute to 172.20.20.10 (172.20.20.10), 32 hops max, 72 byte packets
 1 169.254.0.1 0 ms 0 ms 0 ms
 2 169.254.0.66 0 ms 0 ms 0 ms
 3 172.20.20.10 0 ms 0 ms 0 ms
```

Both HA heartbeat and data traffic are supported on the same FortiGate interface. All heartbeat communication takes place on a separate VDOM called `vsys_ha`. Heartbeat traffic uses a virtual interface called `port_ha` in the `vsys_ha` VDOM. Data and heartbeat traffic use the same physical interface, but they're logically separated into separate VDOMs.

Heartbeat packet Ethertypes

Normal IP packets are 802.3 packets that have an Ethernet type (Ethertype) field value of 0x0800. Ether type values other than 0x0800 are understood as level 2 frames rather than IP packets.

By default, HA heartbeat packets use the following Ethertypes:

- HA heartbeat packets for NAT mode clusters use Ether type 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for transparent mode clusters use Ether type 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `hc-eth-type` option of the `config system ha` command.
- HA telnet sessions between cluster units over HA heartbeat links use Ether type 0x8893. The telnet sessions allow an administrator to connect between FortiGates in the cluster using the `execute ha manage` command. You can change the Ether type of these packets using the `l2ep-eth-type` option of the `config system ha` command.

Because heartbeat packets are recognized as level 2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethertypes for other purposes. For example, Cisco N5K/Nexus switches use Ether type 0x8890 for some functions. When one of these switches receives Ether type 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGates connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

Alternatively, you can use the following CLI options to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ether type of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ether type of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
    set ha-eth-type 8895
    set l2ep-eth-type 889f
end
```

Modifying heartbeat timing

In an HA cluster, if a cluster unit CPU becomes very busy, the cluster unit may not be able to send heartbeat packets on time. If heartbeat packets are not sent on time other units in the cluster may think that the cluster unit has failed and the cluster will experience a failover.

A cluster unit CPU may become very busy if the cluster is subject to a syn flood attack, if network traffic is very heavy, or for other similar reasons. You can use the following CLI commands to configure how the cluster times HA heartbeat packets:

```
config system ha
    set hb-interval <interval_integer>
    set hb-lost-threshold <threshold_integer>
    set hello-holddown <holddown_integer>
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that are not received from another cluster unit before assuming that the cluster unit has failed. The default value is 6, meaning that if the 6 heartbeat packets are not received from a cluster unit then that cluster unit is considered to have failed. The range is 1 to 60 packets.

If the primary unit does not receive a heartbeat packet from a subordinate unit before the heartbeat threshold expires, the primary unit assumes that the subordinate unit has failed.

If a subordinate unit does not receive a heartbeat packet from the primary unit before the heartbeat threshold expires, the subordinate unit assumes that the primary unit has failed. The subordinate unit then begins negotiating to become the new primary unit.

The lower the `hb-lost-threshold` the faster a cluster responds when a unit fails. However, sometimes heartbeat packets may not be sent because a cluster unit is very busy. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following CLI command to increase the lost heartbeat threshold to 12:

```
config system ha
    set hb-lost-threshold 12
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

The HA heartbeat packets consume more bandwidth if the heartbeat interval is short. But if the heartbeat interval is very long, the cluster is not as sensitive to topology and other network changes.

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
    set hb-interval 10
end
```

The heartbeat interval combines with the lost heartbeat threshold to set how long a cluster unit waits before assuming that another cluster unit has failed and is no longer sending heartbeat packets. By default, if a cluster unit does not receive a heartbeat packet from a cluster unit for $6 * 200 = 1200$ milliseconds or 1.2 seconds the cluster unit assumes that the other cluster unit has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after $30 * 2000$ milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following CLI command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
    set hb-lost-threshold 30
    set hb-interval 20
end
```

Changing the time to wait in the hello state

The hello state hold-down time is the number of seconds that a cluster unit waits before changing from hello state to work state. After a failure or when starting up, cluster units operate in the hello state to send and receive heartbeat packets so that all the cluster units can find each other and form a cluster. A cluster unit should change from the hello state to work state after it finds all of the other FortiGate to form a cluster with. If for some reason all cluster units cannot find each other during the hello state then some cluster units may be joining the cluster after it has formed. This can cause disruptions to the cluster and affect how it operates.

One reason for a delay in all of the cluster units joining the cluster could be the cluster units are located at different sites or if for some other reason communication is delayed between the heartbeat interfaces.

If cluster units are joining your cluster after it has started up or if it takes a while for units to join the cluster you can increase the time that the cluster units wait in the hello state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following CLI command to increase the time to wait in the hello state to 1 minute (60 seconds):

```
config system ha
    set hello-holddown 60
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
```

```
set authentication enable
set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

Heartbeat bandwidth requirements

The majority of the traffic processed by the HA heartbeat interface is session synchronization traffic. Other heartbeat interface traffic required to synchronize IPsec state/keys, routing tables, configuration changes, and so on is usually negligible.

The amount of traffic required for session synchronization depends on the connections per second (CPS) that the cluster is processing since only new sessions (and session table updates) need to be synchronized.

Another factor to consider is that if session pickup is enabled, traffic on the heartbeat interface surges during a failover or when a unit joins or re-joins the cluster. When one of these events happens, the whole session table needs to be synchronized. Lower bandwidth HA heartbeat interfaces may increase failover time if they can't handle the higher demand during these events.

You can also reduce the amount of heartbeat traffic by:

- Turning off session pickup if you don't need it,
- Configuring `session-pickup-delay` to reduce the number of sessions that are synchronized,
- Using the `session-sync-dev` option to move session synchronization traffic off of the heartbeat link.

See [Improving session synchronization performance on page 1954](#) for details.

Cluster virtual MAC addresses

When a cluster is operating, the FGCP assigns virtual MAC addresses to each primary unit interface. HA uses virtual MAC addresses so that if a failover occurs, the new primary unit interfaces will have the same virtual MAC addresses and IP addresses as the failed primary unit. As a result, most network equipment would identify the new primary unit as the exact same device as the failed primary unit.

If the MAC addresses changed after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in NAT mode, the FGCP assigns a different virtual MAC address to each primary unit interface. VLAN subinterfaces are assigned the same virtual MAC address as the physical interface that the VLAN subinterface is added to. Redundant interfaces or 802.3ad aggregate interfaces are assigned the virtual MAC address of the first interface in the redundant or aggregate list.

If a cluster is operating in transparent mode, the FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

A MAC address conflict can occur if two clusters are operating on the same network. See [Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1923](#) for more information.

Subordinate unit MAC addresses do not change. You can verify this by connecting to the subordinate unit CLI and using the `get hardware interface nic` command to display the MAC addresses of each FortiGate interface.

The MAC address of a reserved management interface is not changed to a virtual MAC address. Instead the reserved management interface keeps its original MAC address.

When the new primary unit is selected after a failover, the primary unit sends gratuitous ARP packets to update the devices connected to the cluster interfaces (usually layer-2 switches) with the virtual MAC address. Gratuitous ARP packets configure connected network devices to associate the cluster virtual MAC addresses and cluster IP address with primary unit physical interfaces and with the layer-2 switch physical interfaces. This is sometimes called using gratuitous ARP packets (sometimes called GARP packets) to train the network. The gratuitous ARP packets sent from the primary unit are intended to make sure that the layer-2 switch forwarding databases (FDBs) are updated as quickly as possible.

Sending gratuitous ARP packets is not required for routers and hosts on the network because the new primary unit will have the same MAC and IP addresses as the failed primary unit. However, since the new primary unit interfaces are connected to different switch interfaces than the failed primary unit, many network switches will update their FDBs more quickly after a failover if the new primary unit sends gratuitous ARP packets.

Changing how the primary unit sends gratuitous ARP packets after a failover

When a failover occurs it is important that the devices connected to the primary unit update their FDBs as quickly as possible to reestablish traffic forwarding.

Depending on your network configuration, you may be able to change the number of gratuitous ARP packets and the time interval between ARP packets to reduce the cluster failover time.

You cannot disable sending gratuitous ARP packets, but you can use the following command to change the number of packets that are sent. For example, enter the following command to send 20 gratuitous ARP packets:

```
config system ha
    set arps 20
end
```

You can use this command to configure the primary unit to send from 1 to 60 ARP packets. Usually you would not change the default setting of 5. In some cases, however, you might want to reduce the number of gratuitous ARP packets. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending a higher number gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully, you could reduce the number of gratuitous ARP packets that are sent to reduce the amount of traffic produced after a failover.

If failover is taking longer than expected, you may be able to reduce the failover time by increasing the number of gratuitous ARP packets sent.

You can also use the following command to change the time interval in seconds between gratuitous ARP packets. For example, enter the following command to change the time between ARP packets to 3 seconds:

```
config system ha
    set arps-interval 3
end
```

The time interval can be in the range of 1 to 20 seconds. The default is 8 seconds between gratuitous ARP packets. Normally you would not need to change the time interval. However, you could decrease the time to be able to send more packets in less time if your cluster takes a long time to failover.

There may also be a number of reasons to set the interval higher. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending gratuitous

ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully you could increase the interval to reduce the amount of traffic produced after a failover.

For more information about gratuitous ARP packets see [RFC 826](#) and [RFC 3927](#).

Disabling gratuitous ARP packets after a failover

You can use the following command to turn off sending gratuitous ARP packets after a failover:

```
config system ha
    set gratuitous-arps disable
end
```

Sending gratuitous ARP packets is turned on by default.

In most cases you would want to send gratuitous ARP packets because its a reliable way for the cluster to notify the network to send traffic to the new primary unit. However, in some cases, sending gratuitous ARP packets may be less optimal. For example, if you have a cluster of FortiGates in transparent mode, after a failover the new primary unit will send gratuitous ARP packets to all of the addresses in its Forwarding Database (FDB). If the FDB has a large number of addresses it may take extra time to send all the packets and the sudden burst of traffic could disrupt the network.

If you choose to disable sending gratuitous ARP packets you must first enable the `link-failed-signal` setting. The cluster must have some way of informing attached network devices that a failover has occurred.

For more information about the `link-failed-signal` setting, see [Updating MAC forwarding tables when a link failover occurs on page 1940](#).

How the virtual MAC address is determined

The virtual MAC address is determined based on following formula:

```
00-09-0f-09-<group-id_hex>-(<vcluster_integer> + <idx>)
```

where

`<group-id_hex>` is the HA Group ID for the cluster converted to hexadecimal. The following table lists the virtual MAC address set for each group ID.

HA group ID in integer and hexadecimal format

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
4	04
...	...

Integer Group ID	Hexadecimal Group ID
10	0a
11	0b
...	...
63	3f
...	...
255	ff

`<vcluster_integer>` is 0 for virtual cluster 1 and 20 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.

`<idx>` is the index number of the interface. Interfaces are numbered from 0 to x (where x is the number of interfaces). Interfaces are numbered according to their has map order. See [Interface index and display order on page 1914](#). The first interface has an index of 0. The second interface in the list has an index of 1 and so on.

Only the `<idx>` part of the virtual MAC address is different for each interface. The `<vcluster_integer>` would be different for different interfaces if multiple VDOMs have been added.

Between FortiOS releases interface indexing may change so the virtual MAC addresses assigned to individual FortiGate interfaces may also change.

Example virtual MAC addresses

An HA cluster with HA group ID unchanged (default=0) and virtual domains not enabled would have the following virtual MAC addresses for interfaces port1 to port12:

- port1 virtual MAC: 00-09-0f-09-00-00
- port10 virtual MAC: 00-09-0f-09-00-01
- port2 virtual MAC: 00-09-0f-09-00-02
- port3 virtual MAC: 00-09-0f-09-00-03
- port4 virtual MAC: 00-09-0f-09-00-04
- port5 virtual MAC: 00-09-0f-09-00-05
- port6 virtual MAC: 00-09-0f-09-00-06
- port7 virtual MAC: 00-09-0f-09-00-07
- port8 virtual MAC: 00-09-0f-09-00-08
- port9 virtual MAC: 00-09-0f-09-00-

- port11 virtual MAC: 00-09-0f-09-00-0a
- port12 virtual MAC: 00-09-0f-09-00-0b

If the group ID is changed to 34 these virtual MAC addresses change to:

- port1 virtual MAC: 00-09-0f-09-22-00
- port3 virtual MAC: 00-09-0f-09-22-03
- port4 virtual MAC: 00-09-0f-09-22-04
- port5 virtual MAC: 00-09-0f-09-22-05
- port6 virtual MAC: 00-09-0f-09-22-06
- port7 virtual MAC: 00-09-0f-09-22-07
- port8 virtual MAC: 00-09-0f-09-22-08
- port9 virtual MAC: 00-09-0f-09-22-
- port11 virtual MAC: 00-09-0f-09-22-0a
- port12 virtual MAC: 00-09-0f-09-22-0b
- port10 virtual MAC: 00-09-0f-09-22-01
- port2 virtual MAC: 00-09-0f-09-22-02

A cluster with virtual domains enabled where the HA group ID has been changed to 23, port5 and port 6 are in the root virtual domain (which is in virtual cluster1), and port7 and port8 are in the vdom_1 virtual domain (which is in virtual cluster 2) would have the following virtual MAC addresses:

- port5 interface virtual MAC: 00-09-0f-09-23-05
- port6 interface virtual MAC: 00-09-0f-09-23-06
- port7 interface virtual MAC: 00-09-0f-09-23-27
- port8 interface virtual MAC: 00-09-0f-09-23-28

Displaying the virtual MAC address

Every FortiGate physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, it is the actual MAC address of the interface hardware. The current hardware address can be changed. The current hardware address is the address seen by the network. For a FortiGate not operating in HA, you can use the following command to change the current hardware address of the port1 interface:

```
config system interface
  edit port1
    set macaddr <mac_address>
  end
end
```

For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP. The `macaddr` option is not available for a functioning cluster. You cannot change an interface MAC address and you cannot view MAC addresses from the `system interface` CLI command.

You can use the `get hardware nic <interface_name_str>` command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface. Depending on their hardware configuration, this command may display different information for different interfaces. You can use this command to display the current hardware address as `Current_HWaddr` and the permanent hardware address as `Permanent_HWaddr`. For some interfaces the current hardware address is displayed as `MAC`. The command displays a great deal of information about the interface so you may have to scroll the output to find the hardware addresses.

You can also use the `diagnose hardware deviceinfo nic <interface_str>` command to display both MAC addresses for any FortiGate interface.

Before HA configuration the current and permanent hardware addresses are the same. For example for one of the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 02:09:0f:78:18:c9
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

During HA operation the current hardware address becomes the HA virtual MAC address, for example for the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

The following command output for Cluster_2 shows the same current hardware address for port1 as for the internal interface of Cluster_2, indicating a MAC address conflict.

```
FG300A2904500238 # get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 00:09:0F:85:40:FD
.
.
.
```

Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain

A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID.

This section describes a topology that can result in packet loss, how to determine if packets are being lost, and how to correct the problem by changing the HA Group ID.

Packet loss on a network can also be caused by IP address conflicts. Finding and fixing IP address conflicts can be difficult. However, if you are experiencing packet loss and your network contains two FortiGate HA clusters you can use the information in this article to eliminate one possible source of packet loss.

Changing the HA group ID to avoid MAC address conflicts

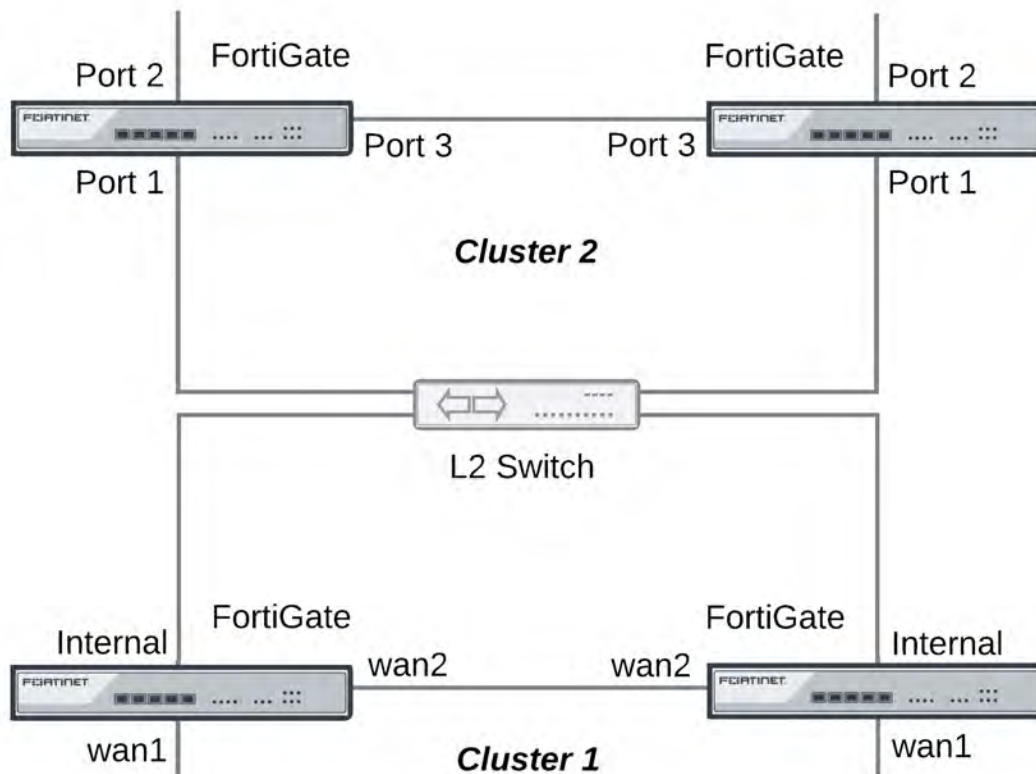

Change the Group ID to change the virtual MAC address of all cluster interfaces. You can change the Group ID from the FortiGate CLI using the following command:

```
config system ha
    set group-id <id_integer>
end
```

Example topology

The topology below shows two clusters. The Cluster_1 internal interfaces and the Cluster_2 port 1 interfaces are both connected to the same broadcast domain. In this topology the broadcast domain could be an internal network. Both clusters could also be connected to the Internet or to different networks.

Example HA topology with possible MAC address conflicts

Ping testing for packet loss

If the network is experiencing packet loss, it is possible that you will not notice a problem unless you are constantly pinging both HA clusters. During normal operation of the network you also might not notice packet loss because the loss rate may not be severe enough to timeout TCP sessions. Also many common types of TCP traffic, such as web browsing, may not be greatly affected by packet loss. However, packet loss can have a significant effect on real time protocols that deliver audio and video data.

To test for packet loss you can set up two constant ping sessions, one to each cluster. If packet loss is occurring the two ping sessions should show alternating replies and timeouts from each cluster.

Cluster_1	Cluster_2
reply	timeout
reply	timeout
reply	timeout
timeout	reply
timeout	reply
reply	timeout
reply	timeout
timeout	reply
timeout	reply
timeout	reply
timeout	reply

Viewing MAC address conflicts on attached switches

If two HA clusters with the same virtual MAC address are connected to the same broadcast domain (L2 switch or hub), the MAC address will conflict and bounce between the two clusters. This example Cisco switch MAC address table shows the MAC address flapping between different interfaces (1/0/1 and 1/0/4).

```
1 0009.0f09.0002 DYNAMIC Gi1/0/1
1 0009.0f09.0002 DYNAMIC Gi1/0/4
```

Synchronizing the configuration

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit.

The following settings are not synchronized between cluster units:

- HA override.
- HA device priority.
- The virtual cluster priority.
- The FortiGate host name.
- The HA priority setting for a ping server (or dead gateway detection) configuration.
- The system interface settings of the HA reserved management interface.
- The HA default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.

The primary unit synchronizes all other configuration settings, including the other HA configuration settings.

All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets.

Disabling automatic configuration synchronization

In some cases you may want to use the following command to disable automatic synchronization of the primary unit configuration to all cluster units.

```
config system ha
    set sync-config disable
end
```

When this option is disabled the cluster no longer synchronizes configuration changes. If a device failure occurs, the new primary unit may not have the same configuration as the failed primary unit. As a result, the new primary unit may process sessions differently or may not function on the network in the same way.

In most cases you should not disable automatic configuration synchronization. However, if you have disabled this feature you can use the `execute ha synchronize` command to manually synchronize a subordinate unit's configuration to that of the primary unit.

You must enter `execute ha synchronize` commands from the subordinate unit that you want to synchronize with the primary unit. Use the `execute ha manage` command to access a subordinate unit CLI.

For example, to access the first subordinate unit and force a synchronization at any time, even if automatic synchronization is disabled enter:

```
execute ha manage 0
execute ha synchronize start
```

You can use the following command to stop a synchronization that is in progress.

```
execute ha synchronize stop
```

Incremental synchronization

When you log into the cluster GUI or CLI to make configuration changes, you are actually logging into the primary unit. All of your configuration changes are first made to the primary unit. Incremental synchronization then immediately synchronizes these changes to all of the subordinate units.

When you log into a subordinate unit CLI (for example using `execute ha manage`) all of the configuration changes that you make to the subordinate unit are also immediately synchronized to all cluster units, including the primary unit, using the same process.

Incremental synchronization also synchronizes other dynamic configuration information such as the DHCP server address lease database, routing table updates, IPsec SAs, MAC address tables, and so on. See [FortiGate HA compatibility with DHCP and PPPoE on page 1756](#) for more information about DHCP server address lease

synchronization and [Synchronizing kernel routing tables on page 1933](#) for information about routing table updates.

Whenever a change is made to a cluster unit configuration, incremental synchronization sends the same configuration change to all other cluster units over the HA heartbeat link. An HA synchronization process running on the each cluster unit receives the configuration change and applies it to the cluster unit. The HA synchronization process makes the configuration change by entering a CLI command that appears to be entered by the administrator who made the configuration change in the first place.

Synchronization takes place silently, and no log messages are recorded about the synchronization activity. However, log messages can be recorded by the cluster units when the synchronization process enters CLI commands. You can see these log messages on the subordinate units if you enable event logging and set the minimum severity level to **Information** and then check the event log messages written by the cluster units when you make a configuration change.

You can also see these log messages on the primary unit if you make configuration changes from a subordinate unit.

Periodic synchronization

Incremental synchronization makes sure that as an administrator makes configuration changes, the configurations of all cluster units remain the same. However, a number of factors could cause one or more cluster units to go out of sync with the primary unit. For example, if you add a new unit to a functioning cluster, the configuration of this new unit will not match the configuration of the other cluster units. Its not practical to use incremental synchronization to change the configuration of the new unit.

Periodic synchronization is a mechanism that looks for synchronization problems and fixes them. Every minute the cluster compares the configuration file checksum of the primary unit with the configuration file checksums of each of the subordinate units. If all subordinate unit checksums are the same as the primary unit checksum, all cluster units are considered synchronized.

If one or more of the subordinate unit checksums is not the same as the primary unit checksum, the subordinate unit configuration is considered out of sync with the primary unit. The checksum of the out of sync subordinate unit is checked again every 15 seconds. This re-checking occurs in case the configurations are out of sync because an incremental configuration sequence has not completed. If the checksums do not match after 5 checks the subordinate unit that is out of sync retrieves the configuration from the primary unit. The subordinate unit then reloads its configuration and resumes operating as a subordinate unit with the same configuration as the primary unit.

The configuration of the subordinate unit is reset in this way because when a subordinate unit configuration gets out of sync with the primary unit configuration there is no efficient way to determine what the configuration differences are and to correct them. Resetting the subordinate unit configuration becomes the most efficient way to resynchronize the subordinate unit.

Synchronization requires that all cluster units run the same FortiOS firmware build. If some cluster units are running different firmware builds, then unstable cluster operation may occur and the cluster units may not be able to synchronize correctly.

Re-installing the firmware build running on the primary unit forces the primary unit to upgrade all cluster units to the same firmware build.

Console messages when configuration synchronization succeeds

When a cluster first forms, or when a new unit is added to a cluster as a subordinate unit, the following messages appear on the CLI console to indicate that the unit joined the cluster and had its configuring synchronized with the primary unit.

```
slave's configuration is not in sync with master's, sequence:0
slave's configuration is not in sync with master's, sequence:1
  slave's configuration is not in sync with master's, sequence:2
  slave's configuration is not in sync with master's, sequence:3
  slave's configuration is not in sync with master's, sequence:4
  slave starts to sync with master
logout all admin users
slave succeeded to sync with master
```

Console messages when configuration synchronization fails

If you connect to the console of a subordinate unit that is out of synchronization with the primary unit, messages similar to the following are displayed.

```
slave is not in sync with master, sequence:0. (type 0x3)
slave is not in sync with master, sequence:1. (type 0x3)
slave is not in sync with master, sequence:2. (type 0x3)
slave is not in sync with master, sequence:3. (type 0x3)
slave is not in sync with master, sequence:4. (type 0x3)
global compared not matched
```

If synchronization problems occur the console message sequence may be repeated over and over again. The messages all include a type value (in the example `type 0x3`). The type value can help Fortinet Support diagnose the synchronization problem.

HA out of sync object messages and the configuration objects that they reference

Out of Sync Message	Configuration Object

Comparing checksums of cluster units

You can use the `diagnose sys ha checksum show` command to compare the configuration checksums of all cluster units. The output of this command shows checksums labeled `global` and `all` as well as checksums for each of the VDOMs including the `root` VDOM. The `get system ha-nonsync-csum` command can be used to display similar information; however, this command is intended to be used by FortiManager.

The primary unit and subordinate unit checksums should be the same. If they are not you can use the `execute ha synchronize start` command to force a synchronization.

The following command output is for the primary unit of a cluster that does not have multiple VDOMs enabled:

```
diagnose sys ha checksum show
is_manage_master()=1, is_root_master()=1
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following command output is for a subordinate unit of the same cluster:

```
diagnose sys ha checksum show
is_manage_master()=0, is_root_master()=0
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following example shows using this command for the primary unit of a cluster with multiple VDOMs. Two VDOMs have been added named `test` and `Eng_vdm`.

From the primary unit:

```
config global
  diagnose sys ha checksum show
  is_manage_master()=1, is_root_master()=1
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test:  a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root:  3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

checksum
global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
test:  a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
root:  3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

From the subordinate unit:

```
config global
  diagnose sys ha checksum show
  is_manage_master()=0, is_root_master()=0
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test:  a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root:  3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

checksum
global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
test:  a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
root:  3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

How to diagnose HA out of sync messages

This section describes how to use the `diagnose sys ha checksum show` and `diagnose debug` commands to diagnose the cause of HA out of sync messages.

If HA synchronization is not successful, use the following procedures on each cluster unit to find the cause.

To determine why HA synchronization does not occur

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following commands to enable debugging and display HA out of sync messages.

```
diagnose debug enable
diagnose debug console timestamp enable
diagnose debug application hataalk -1
diagnose debug application hasync -1
```

Collect the console output and compare the out of sync messages with the information in the table

[HA out of sync object messages and the configuration objects that they reference on page 1928.](#)

3. Enter the following commands to turn off debugging.

```
diagnose debug disable
diagnose debug reset
```

To determine what part of the configuration is causing the problem

If the previous procedure displays messages that include sync object 0x30 (for example, HA_SYNC_SETTING_CONFIGURATION = 0x03) there is a synchronization problem with the configuration. Use the following steps to determine the part of the configuration that is causing the problem.

If your cluster consists of two cluster units, use this procedure to capture the configuration checksums for each unit. If your cluster consists of more than two cluster units, repeat this procedure for all cluster units that returned messages that include 0x30 sync object messages.

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following command to turn on terminal capture

```
diagnose debug enable
```

3. Enter the following command to stop HA synchronization.

```
execute ha sync stop
```

4. Enter the following command to display configuration checksums.

```
diagnose sys ha checksum show global
```

5. Copy the output to a text file.
6. Repeat for all affected units.
7. Compare the text file from the primary unit with the text file from each cluster unit to find the checksums that do not match.

You can use a diff function to compare text files.

8. Repeat for the root VDOM:

```
diagnose sys ha checksum show root
```

9. Repeat for all VDOMS (if multiple VDOM configuration is enabled):

```
diagnose sys ha checksum show <vdom-name>
```

10. You can also use the `grep` option to just display checksums for parts of the configuration.

For example to display system related configuration checksums in the root VDOM or log-related checksums in the global configuration:

```
diagnose sys ha checksum root | grep system
diagnose sys ha checksum global | grep log
```

Generally it is the first non-matching checksum that is the cause of the synchronization problem.

11. Attempt to remove/change the part of the configuration that is causing the problem. You can do this by making configuration changes from the primary unit or subordinate unit CLI.
12. Enter the following commands to start HA configuration and stop debugging:

```
execute ha sync start
diagnose debug disable
diagnose debug reset
```

Recalculating the checksums to resolve out of sync messages

Sometimes an error can occur when checksums are being calculated by the cluster. As a result of this calculation error the CLI console could display out of sync error messages even though the cluster is otherwise operating normally. You can also sometimes see checksum calculation errors in `diagnose sys ha checksum` command output when the checksums listed in the `debugzone` output don't match the checksums in the `checksum` part of the output.

One solution to this problem could be to re-calculate the checksums. The re-calculated checksums should match and the out of sync error messages should stop appearing.

You can use the following command to re-calculate HA checksums:

```
diagnose sys ha checksum recalculate [<vdom-name> | global]
```

Just entering the command without options recalculates all checksums. You can specify a VDOM name to just recalculate the checksums for that VDOM. You can also enter `global` to recalculate the global checksum.

Synchronizing kernel routing tables

In a functioning cluster, the primary unit keeps all subordinate unit kernel routing tables (also called the forwarding information base FIB) up to date and synchronized with the primary unit. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets. After a failover, because of these routing table updates the new primary unit does not have to populate its kernel routing table before being able to route traffic. This gives the new primary unit time to rebuild its regular routing table after a failover.

Use the following command to view the regular routing table. This table contains all of the configured routes and routes acquired from dynamic routing protocols and so on. This routing table is not synchronized. On subordinate units this command will not produce the same output as on the primary unit.

```
get router info routing-table
```

Use the following command to view the kernel routing table (FIB). This is the list of resolved routes actually being used by the FortiOS kernel. The output of this command should be the same on the primary unit and the subordinate units.

```
get router info kernel
```

This section describes how clusters handle dynamic routing failover and also describes how to use CLI commands to control the timing of routing table updates of the subordinate unit routing tables from the primary unit.

Controlling how the FGCP synchronizes kernel routing table updates

You can use the following commands to control some of the timing settings that the FGCP uses when synchronizing routing updates from the primary unit to subordinate units and maintaining routes on the primary unit after a failover.

```
config system ha
  set route-hold <hold_integer>
  set route-ttl <ttl_integer>
  set route-wait <wait_integer>
end
```

Change how long routes stay in a cluster unit routing table

Change the `route-ttl` time to control how long routes remain in a cluster unit routing table. The time to live range is 5 to 3600 seconds. The default time to live is 10 seconds.

The time to live controls how long routes remain active in a cluster unit routing table after the cluster unit becomes a primary unit. To maintain communication sessions after a cluster unit becomes a primary unit, routes remain active in the routing table for the route time to live while the new primary unit acquires new routes.

By default, `route-ttl` is set to 10 which may mean that only a few routes will remain in the routing table after a failover. Normally keeping `route-ttl` to 10 or reducing the value to 5 is acceptable because acquiring new routes usually occurs very quickly, especially if graceful restart is enabled, so only a minor delay is caused by acquiring new routes.

If the primary unit needs to acquire a very large number of routes, or if for other reasons, there is a delay in acquiring all routes, the primary unit may not be able to maintain all communication sessions.

You can increase the route time to live if you find that communication sessions are lost after a failover so that the primary unit can use synchronized routes that are already in the routing table, instead of waiting to acquire new routes.

Change the time between routing updates

Change the `route-hold` time to change the time that the primary unit waits between sending routing table updates to subordinate units. The route hold range is 0 to 3600 seconds. The default route hold time is 10 seconds.

To avoid flooding routing table updates to subordinate units, set `route-hold` to a relatively long time to prevent subsequent updates from occurring too quickly. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Increasing the time between updates means that this data exchange will not have to happen so often.

The `route-hold` time should be coordinated with the `route-wait` time.

Change the time the primary unit waits after receiving a routing update

Change the `route-wait` time to change how long the primary unit waits after receiving routing updates before sending the updates to the subordinate units. For quick routing table updates to occur, set `route-wait` to a relatively short time so that the primary unit does not hold routing table changes for too long before updating the subordinate units.

The `route-wait` range is 0 to 3600 seconds. The default `route-wait` is 0 seconds.

Normally, because the `route-wait` time is 0 seconds the primary unit sends routing table updates to the subordinate units every time its routing table changes.

Once a routing table update is sent, the primary unit waits the `route-hold` time before sending the next update.

Usually routing table updates are periodic and sporadic. Subordinate units should receive these changes as soon as possible so `route-wait` is set to 0 seconds. `route-hold` can be set to a relatively long time because normally the next route update would not occur for a while.

In some cases, routing table updates can occur in bursts. A large burst of routing table updates can occur if a router or a link on a network fails or changes. When a burst of routing table updates occurs, there is a potential that the primary unit could flood the subordinate units with routing table updates. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Setting `route-wait` to a longer time reduces the frequency of additional updates and prevents flooding of routing table updates from occurring.

Configuring graceful restart for dynamic routing failover

When an HA failover occurs, neighbor routers will detect that the cluster has failed and remove it from the network until the routing topology stabilizes. During that time the routers may stop sending IP packets to the cluster and communication sessions that would normally be processed by the cluster may time out or be dropped. Also the new primary unit will not receive routing updates and so will not be able to build and maintain its routing database.

You can solve this problem by configuring graceful restart for the dynamic routing protocols that you are using. This section describes configuring graceful restart for OSPF and BGP.

To support graceful restart you should make sure the new primary unit keeps its synchronized routing data long enough to acquire new routing data. You should also increase the HA route time to live, route wait, and route hold values to 60 using the following CLI command:

```
config system ha
  set route-ttl 60
  set route-wait 60
  set route-hold 60
end
```

Graceful OSPF restart

You can configure graceful restart (also called nonstop forwarding (NSF)) as described in [RFC3623](#) (Graceful OSPF Restart) to solve the problem of dynamic routing failover. If graceful restart is enabled on neighbor routers, they will keep sending packets to the cluster following the HA failover instead of removing it from the network. The neighboring routers assume that the cluster is experiencing a graceful restart.

After the failover, the new primary unit can continue to process communication sessions using the synchronized routing data received from the failed primary unit before the failover. This gives the new primary unit time to update its routing table after the failover.

You can use the following commands to enable graceful restart or NSF on Cisco routers:

```
router ospf 1
  log-adjacency-changes
  nsf ietf helper strict-lsa-checking
```

If the cluster is running OSPF, use the following command to enable graceful restart for OSPF:

```
config router ospf
  set restart-mode graceful-restart
end
```

Graceful BGP restart

If the cluster is running BGP only the primary unit keeps BGP peering connections. When a failover occurs, the BGP peering needs to be reestablished. This will happen if you enable BGP graceful restart which causes the adjacent routers to keep the routes active while the BGP peering is restarted by the new primary unit.

Enabling BGP graceful restart causes the FortiGate's BGP process to restart which can temporarily disrupt traffic through the cluster. So normally you should wait for a quiet time or a maintenance period to enable BGP graceful restart.

Use the following command to enable graceful restart for BGP and set some graceful restart options.

```
config router bgp
```

```
set graceful-restart enable
set graceful-restart-time 120
set graceful-stalepath-time 360
set graceful-update-delay 120
end
```

Notifying BGP neighbors when graceful restart is enabled

You can add BGP neighbors and configure the cluster unit to notify these neighbors that it supports graceful restart.

```
config router bgp
  config neighbor
    edit <neighbor_address_Ipv4>
      set capability-graceful-restart enable
    end
  end
end
```

Bidirectional Forwarding Detection (BFD) enabled BGP graceful restart

You can add a BFD enabled BGP neighbor as a static BFD neighbor using the following command. This example shows how to add a BFD neighbor with IP address 172.20.121.23 that is on the network connected to port4:

```
config router bfd
  config neighbor
    edit 172.20.121.23
      set port4
    end
  end
end
```

The FGCP supports graceful restart of BFD enabled BGP neighbors. The `config router bfd` command is needed as the BGP auto-start timer is 5 seconds. After HA failover, BGP on the new primary unit has to wait for 5 seconds to connect to its neighbors, and then register BFD requests after establishing the connections. With static BFD neighbors, BFD requests and sessions can be created as soon as possible after the failover. The new command `get router info bfd requests` shows the BFD peer requests.

A BFD session created for a static BFD neighbor/peer request will initialize its state as "INIT" instead of "DOWN" and its detection time `asbfd-required-min-rx * bfd-detect-mult` milliseconds.

When a BFD control packet with nonzero `your_discr` is received, if no session can be found to match the `your_discr`, instead of discarding the packet, other fields in the packet, such as addressing information, are used to choose one session that was just initialized, with zero as its remote discriminator.

When a BFD session in the up state receives a control packet with zero as `your_discr` and down as the state, the session will change its state into down but will not notify this down event to BGP and/or other registered clients.

Link failover (port monitoring or interface monitoring)

Link failover means that if a monitored interface fails, the cluster reorganizes to reestablish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

You configure monitored interfaces (also called interface monitoring or port monitoring) by selecting the interfaces to monitor as part of the cluster HA configuration.

You can monitor up to 64 interfaces.

The interfaces that you can monitor appear on the port monitor list. You can monitor all FortiGate interfaces including redundant interfaces and 802.3ad aggregate interfaces.

You cannot monitor the following types of interfaces (you cannot select the interfaces on the port monitor list):

- FortiGate interfaces that contain an internal switch.
- VLAN subinterfaces.
- IPsec VPN interfaces.
- Individual physical interfaces that have been added to a redundant or 802.3ad aggregate interface.
- FortiGate-5000 series backplane interfaces that have not been configured as network interfaces.

If you are configuring a virtual cluster you can create a different port monitor configuration for each virtual cluster. Usually for each virtual cluster you would monitor the interfaces that have been added to the virtual domains in each virtual cluster.

Wait until after the cluster is up and running to enable interface monitoring. You do not need to configure interface monitoring to get a cluster up and running and interface monitoring will cause failovers if for some reason during initial setup a monitored interface has become disconnected. You can always enable interface monitoring once you have verified that the cluster is connected and operating properly.

You should only monitor interfaces that are connected to networks, because a failover may occur if you monitor an unconnected interface.

To enable interface monitoring - GUI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster GUI.
2. Go to **System > HA** and edit the primary unit (**Role** is **MASTER**).
3. Select the **Port Monitor** check boxes for the **port1** and **port2** interfaces and select **OK**.

The configuration change is synchronized to all cluster units.

To enable interface monitoring - CLI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster CLI.
2. Enter the following command to enable interface monitoring for port1 and port2.

```
configure system ha
  set monitor port1 port2
end
```

The following example shows how to enable monitoring for the external, internal, and DMZ interfaces.

```
config system ha
  set monitor external internal dmz
end
```

With interface monitoring enabled, during cluster operation, the cluster monitors each cluster unit to determine if the monitored interfaces are operating and connected. Each cluster unit can detect a failure of its network

interface hardware. Cluster units can also detect if its network interfaces are disconnected from the switch they should be connected to.

Cluster units cannot determine if the switch that its interfaces are connected to is still connected to the network. However, you can use remote IP monitoring to make sure that the cluster unit can connect to downstream network devices. See [Remote link failover \(remote IP monitoring\) on page 1943](#).

Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link between a network and the primary unit fails, to maintain communication with this network, the cluster must select a different primary unit; one that is still connected to the network. Unless another link failure has occurred, the new primary unit will have an active link to the network and will be able to maintain communication with it.

To support link failover, each cluster unit stores link state information for all monitored cluster units in a link state database. All cluster units keep this link state database up to date by sharing link state information with the other cluster units. If one of the monitored interfaces on one of the cluster units becomes disconnected or fails, this information is immediately shared with all cluster units.

If a monitored interface on the primary unit fails

If a monitored interface on the primary unit fails, the cluster renegotiates to select a new primary unit using the process described in [Primary unit selection on page 1744](#). Because the cluster unit with the failed monitored interface has the lowest monitor priority, a different cluster unit becomes the primary unit. The new primary unit should have fewer link failures.

After the failover, the cluster resumes and maintains communication sessions in the same way as for a device failure. See [Device failover on page 1910](#).

If a monitored interface on a subordinate unit fails

If a monitored interface on a subordinate unit fails, this information is shared with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster.

In an active-passive cluster after a subordinate unit link failover, the subordinate unit continues to function normally as a subordinate unit in the cluster.

In an active-active cluster after a subordinate unit link failure:

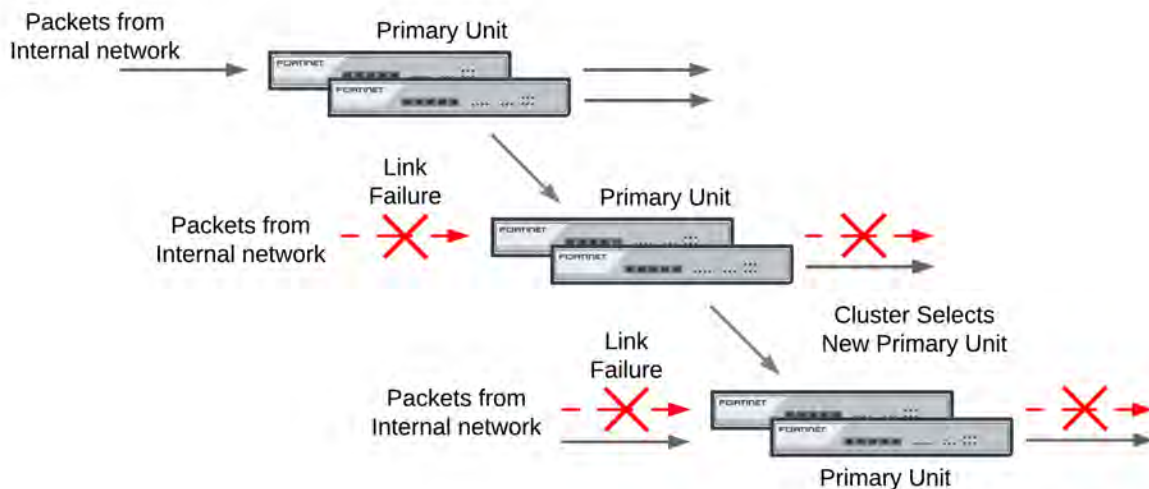

- The subordinate unit with the failed monitored interface can continue processing connections between functioning interfaces. However, the primary unit stops sending sessions to a subordinate unit that use any failed monitored interfaces on the subordinate unit.
- If session pickup is enabled, all sessions being processed by the subordinate unit failed interface that can be failed over are failed over to other cluster units. Sessions that cannot be failed over are lost and have to be restarted.
- If session pickup is not enabled all sessions being processed by the subordinate unit failed interface are lost.

How link failover maintains traffic flow

Monitoring an interface means that the interface is connected to a high priority network. As a high priority network, the cluster should maintain traffic flow to and from the network, even if a link failure occurs. Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link that the primary unit has to a high priority network fails, to maintain

traffic flow to and from this network, the cluster must select a different primary unit. This new primary unit should have an active link to the high priority network.

A link failure causes a cluster to select a new primary unit

If a monitored interface on the primary unit fails, the cluster renegotiates and selects the cluster unit with the highest monitor priority to become the new primary unit. The cluster unit with the highest monitor priority is the cluster unit with the most monitored interfaces connected to networks.

After a link failover, the primary unit processes all traffic and all subordinate units, even the cluster unit with the link failure, share session and link status. In addition all configuration changes, routes, and IPsec SAs are synchronized to the cluster unit with the link failure.

In an active-active cluster, the primary unit load balances traffic to all the units in the cluster. The cluster unit with the link failure can process connections between its functioning interfaces (for, example if the cluster has connections to an internal, external, and DMZ network, the cluster unit with the link failure can still process connections between the external and DMZ networks).

Recovery after a link failover and controlling primary unit selection (controlling falling back to the prior primary unit)

If you find and correct the problem that caused a link failure (for example, re-connect a disconnected network cable) the cluster updates its link state database and re-negotiates to select a primary unit.

What happens next depends on how the cluster configuration affects primary unit selection:

- The former primary unit will once again become the primary unit (falling back to becoming the primary unit)
- The primary unit will not change.

As described in [Primary unit selection and age on page 1747](#), when the link is restored, if no options are configured to control primary unit selection and the cluster age difference is less than 300 seconds the former primary unit will once again become the primary unit. If the age differences are greater than 300 seconds then a new primary unit is not selected. Since you have no control on the age difference the outcome can be unpredictable. This is not a problem in cases where its not important which unit becomes the primary unit.

Preventing a primary unit change after a failed link is restored

Some organizations will not want the cluster to change primary units when the link is restored. Instead they would rather wait to restore the primary unit during a maintenance window. This functionality is not directly supported, but you can experiment with changing some primary unit selection settings. For example, in most cases it should work to enable override on all cluster units and make sure their priorities are the same. This should mean that the primary unit should not change after a failed link is restored.

Then, when you want to restore the original primary unit during a maintenance window you can just set its Device Priority higher. After it becomes the primary unit you can reset all device priorities to the same value. Alternatively during a maintenance window you could reboot the current primary unit and any subordinate units except the one that you want to become the primary unit.

If the `override` CLI keyword is enabled on one or more cluster units and the device priority of a cluster unit is set higher than the others, when the link failure is repaired and the cluster unit with the highest device priority will always become the primary unit.

Testing link failover

You can test link failure by disconnecting the network cable from a monitored interface of a cluster unit. If you disconnect a cable from a primary unit monitored interface the cluster should renegotiate and select one of the other cluster units as the primary unit. You can also verify that traffic received by the disconnected interface continues to be processed by the cluster after the failover.

If you disconnect a cable from a subordinate unit interface the cluster will not renegotiate.

Updating MAC forwarding tables when a link failover occurs

When a FortiGate HA cluster is operating and a monitored interface fails on the primary unit, the primary unit usually becomes a subordinate unit and another cluster unit becomes the primary unit. After a link failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables (also called arp tables) of the switches connected to the cluster. This is normal link failover operation.

Even when gratuitous ARP packets are sent, some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur if the switch does not detect the failure and does not clear its MAC forwarding table.

You have another option available to make sure the switch detects the failover and clears its MAC forwarding tables. You can use the following command to cause a cluster unit with a monitored interface link failure to briefly shut down all of its interfaces (except the heartbeat interfaces) after the failover occurs:

```
config system ha
    set link-failed-signal enable
end
```

Usually this means each interface of the former primary unit is shut down for about a second. When this happens the switch should be able to detect this failure and clear its MAC forwarding tables of the MAC addresses of the former primary unit and pickup the MAC addresses of the new primary unit. Each interface will shut down for a second but the entire process usually takes a few seconds. The more interfaces the FortiGate has, the longer it will take.

Normally, the new primary unit also sends gratuitous ARP packets that also help the switch update its MAC forwarding tables to connect to the new primary unit. If `link-failed-signal` is enabled, sending gratuitous ARP packets is optional and can be disabled if you don't need it or if its causing problems. See [Disabling gratuitous ARP packets after a failover on page 1920](#)

Multiple link failures

Every time a monitored interface fails, the cluster repeats the processes described above. If multiple monitored interfaces fail on more than one cluster unit, the cluster continues to negotiate to select a primary unit that can provide the most network connections.

Example link failover scenarios

For the following examples, assume a cluster configuration consisting of two FortiGate (FGT_1 and FGT_2) connected to three networks: internal using port2, external using port1, and DMZ using port3. In the HA configuration, the device priority of FGT_1 is set higher than the unit priority of FGT_2.

The cluster processes traffic flowing between the internal and external networks, between the internal and DMZ networks, and between the external and DMZ networks. If there are no link failures, FGT1 becomes the primary unit because it has the highest device priority.

Sample link failover scenario topology

Example the port1 link on FGT_1 fails

If the port1 link on FGT_1 fails, FGT_2 becomes primary unit because it has fewer interfaces with a link failure. If the cluster is operating in active-active mode, the cluster load balances traffic between the internal network (port2) and the DMZ network (port3). Traffic between the Internet (port1) and the internal network (port2) and between the Internet (port1) and the DMZ network (port3) is processed by the primary unit only.

Example port2 on FGT_1 and port1 on FGT_2 fail

If port2 on FGT_1 and port1 on FGT_2 fail, then FGT_1 becomes the primary unit. After both of these link failures, both cluster units have the same monitor priority. So the cluster unit with the highest device priority (FGT_1) becomes the primary unit.

Only traffic between the Internet (port1) and DMZ (port3) networks can pass through the cluster and the traffic is handled by the primary unit only. No load balancing will occur if the cluster is operating in active-active mode.

Monitoring VLAN interfaces

If the FortiGates in the cluster have VLAN interfaces, you can use the following command to monitor all VLAN interfaces and write a log message if one of the VLAN interfaces is found to be down.

Once configured, this feature works by verifying that the primary unit can connect to the subordinate unit over each VLAN. This verifies that the switch that the VLAN interfaces are connected to is configured correctly for each VLAN. If the primary unit cannot connect to the subordinate unit over one of the configured VLANs the primary unit writes a link monitor log message indicating that the named VLAN went down (log message id 20099).

Use the following CLI command to enable monitoring VLAN interfaces:

```
config system ha-monitor
  set monitor-vlan enable/disable
  set vlan-hb-interval <interval_seconds>
  set vlan-hb-lost-threshold <vlan-lost-heartbeat-threshold>
end
```

`vlan-hb-interval` is the time between sending VLAN heartbeat packets over the VLAN. The VLAN heartbeat range is 1 to 30 seconds. The default is 5 seconds.

`vlan-hb-lost-threshold` is the number of consecutive VLAN heartbeat packets that are not successfully received across the VLAN before assuming that the VLAN is down. The default value is 3, meaning that if 3 heartbeat packets sent over the VLAN are not received then the VLAN is considered to be down. The range is 1 to 60 packets.

A VLAN heartbeat interval of 5 means the time between heartbeat packets is five seconds. A VLAN heartbeat threshold of 3 means it takes $5 \times 3 = 15$ seconds to detect that a VLAN is down.

Sub-second failover

On FortiGate models 395xB and 3x40B HA link failover supports sub-second failover (that is a failover time of less than one second). Sub-second failover is available for interfaces that can issue a link failure system call when the interface goes down. When an interface experiences a link failure and sends the link failure system call, the FGCP receives the system call and initiates a link failover.

For interfaces that do not support sub-second failover, port monitoring regularly polls the connection status of monitored interfaces. When a check finds that an interface has gone down, port monitoring causes a link failover. Sub-second failover results in a link failure being detected sooner because the system doesn't have to wait for the next poll to find out about the failure.

Sub-second failover can accelerate HA failover to reduce the link failover time to less than one second under ideal conditions. Actual failover performance may vary depending on traffic patterns and network configuration. For example, some network devices may respond slowly to an HA failover.

No configuration changes are required to support sub-second failover. However, for best sub-second failover results, the recommended heartbeat interval is 100ms and the recommended lost heartbeat threshold is 5 (see [Modifying heartbeat timing on page 1916](#)).

```
config system ha
  set hb-lost-threshold 5
  set hb-interval 1
end
```

For information about how to reduce failover times, see [Failover performance on page 1951](#).

Remote link failover (remote IP monitoring)

Remote link failover uses link health monitors on the primary FortiGate to test connectivity with IP addresses of remote network devices, for example, a downstream router. Remote link failover causes a failover if one or more of these remote IP addresses does not respond to link health checking.

By being able to detect failures in network equipment not directly connected to the cluster, remote link failover can be useful in a number of ways depending on your network configuration. For example, in a full mesh HA configuration, with remote IP monitoring, the cluster can detect failures in network equipment that is not directly connected to the cluster but that would interrupt traffic processed by the cluster if the equipment failed.

Example HA remote IP monitoring topology

In the simplified example topology shown above, the switch connected directly to the primary unit is operating normally but the link on the other side of the switch fails. After the failure, traffic can no longer flow between the primary unit and the internet.

To detect this failure you can enable remote link failover and create a link health monitor for port2 that causes the primary unit to test connectivity to 192.168.20.20. If the link health monitor can't connect to 192.268.20.20, the cluster to fails over and the subordinate unit becomes the new primary unit. After the failover, the health check monitor on the new primary unit can connect to 192.168.20.20, so the failover maintains connectivity between the internal network and the internet through the cluster.

Remote link failover is active only on the primary unit and only the primary unit can detect a remote link failure. If the primary unit detects a remote link failure and causes a failover, the new primary unit may also detect this failure and cause another failover.

To reduce the potential number of failovers, remote IP monitoring includes a flip timer, set to a relatively high default value of 60 minutes. The flip timeout stops HA remote link failover from causing a failover until the primary unit has been operating for the duration of the flip timeout.

If you set the flip timeout to a relatively high number of minutes, you can find and repair the network problem that prevented the cluster from connecting to the remote IP address without the cluster experiencing very many failovers. Even if it takes a while to detect the problem, repeated failovers at relatively long time intervals do not usually disrupt network traffic.

Example remote link failover configuration

In most cases you should accept the default remote link failover configuration. The default configuration consists of:

- Enabling HA remote link failover for one or more FortiGate interfaces.
- Enabling link monitoring for those interfaces.

For example, the following configuration enables HA remote IP monitoring for the port2 interface:

```
config system ha
    set pingserver-monitor-interface port2
    set pingserver-failover-threshold 0
    set pingserver-slave-force-reset enable
    set pingserver-flip-timeout 60
end
```

The `pingserver-failover-threshold`, `pingserver-slave-force-reset`, and `pingserver-flip-timeout` options remain set to their default values.

After enabling HA remote link failover, you must configure a link monitor for the interface. The link monitor also includes the remote IP address to monitor. All other options, including the `ha-priority` remain set to defaults:

```
config system link-monitor
    edit ha-link-monitor
        set server 192.168.20.20
        set srcintf port2
        set ha-priority 1
        set interval 1
        set failtime 5
    end
```

This configuration causes the primary unit to check the 192.168.20.20 IP address from the port2 interface and to cause a failover if the link monitor doesn't get a response from this IP address after 5 failed attempts. After a failover occurs, HA remote link failover can't cause another failover for at least 60 minutes. After 60 minutes, the cluster uses the normal primary unit selection process to select a primary unit. After the new primary unit is selected, link monitoring resumes operating as before.

You can adjust this configuration in following ways:

- Enabling remote link failover for more interfaces by adding more interfaces to the `pingserver-monitor-interface`. You must also add a link monitor for each interface.
- If you have enabled override, you can disable `pingserver-slave-force-reset` to reduce the number of failovers. If override is enabled and a remote link failover has occurred, after the flip timeout, even if the current primary unit is not experiencing a remote link failure, if `pingserver-slave-force-reset` is enabled, override

causes the cluster to negotiate and select the FortiGate with the highest priority to become the primary unit. Then, if the remote link has not been restored for the FortiGate with the highest priority, remote link failover may cause another failover. But with override enabled, if `pingserver-slave-force-reset` is disabled, as long as the current primary unit is not experiencing a remote link failure, the cluster will not renegotiate. In brief, disabling `pingserver-slave-force-reset` prevents repeated failovers if the remote link is not restored for both FortiGates when the current primary unit experiences a remote link failure.

- Increase the `interval` or `failtime` to reduce how often a remote link failure is detected.

Changing the link monitor failover threshold

If you have multiple link monitors, you may want a failover to occur only if more than one of them fails.

For example, you may have three link monitors configured on three interfaces but only want a failover to occur if two of the link monitors fail. To do this you must set the HA priorities of the link monitors and the HA `pingserver-failover-threshold` so that the priority of one link monitor is less than the failover threshold but the added priorities of two link monitors is equal to or greater than the failover threshold. Failover occurs when the HA priority of all failed link monitors reaches or exceeds the threshold.

For example, set the failover threshold to 10 and monitor three interfaces:

```
config system ha
  set pingserver-monitor-interface port2 port20 vlan_234
  set pingserver-failover-threshold 10
  set pingserver-flip-timeout 120
end
```

Then set the HA priority of link monitor server to 5.

The HA Priority (`ha-priority`) setting is not synchronized among cluster units. In the following example, you must set the HA priority to 5 by logging into each cluster unit unless you only want this configuration to be active on one of the units in the cluster.

```
config system link-monitor
  edit port2
    set srcintf port2
    set server 192.168.20.20
    set ha-priority 5
  next
  edit port20
    set srcintf port20
    set server 192.168.20.30
    set ha-priority 5
  next
  edit vlan_234
    set srcintf vlan_234
    set server 172.20.12.10
    set ha-priority 5
end
```

If only one of the link monitors fails, the total link monitor HA priority will be 5, which is lower than the failover threshold so a failover will not occur. If a second link monitor fails, the total link monitor HA priority of 10 will equal the failover threshold, causing a failover.

By adding multiple link monitors and setting the HA priorities for each, you can fine tune remote IP monitoring. For example, if it is more important to maintain connections to some networks you can set the HA priorities higher

for these link monitors. And if it is less important to maintain connections to other networks you can set the HA priorities lower for these link monitors. You can also adjust the failover threshold so that if the cluster cannot connect to one or two high priority IP addresses a failover occurs. But a failover will not occur if the cluster cannot connect to one or two low priority IP addresses.

Detecting HA remote IP failover events

Just as with any HA failover, you can detect HA remote link failover events using SNMP to monitor for HA traps. You can also use alert email to receive notifications of HA status changes and monitor log messages for HA failover log messages. In addition, the critical log message `Ping Server is down` is generated when a ping server fails. The log message includes the name of the interface that the ping server that detected the failure.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time experienced by your network users may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Monitoring cluster units for failover

You can use logging and SNMP to monitor cluster units for failover. Both the primary and subordinate units can be configured to write log messages and send SNMP traps if a failover occurs. You can also log into the cluster GUI and CLI to determine if a failover has occurred.

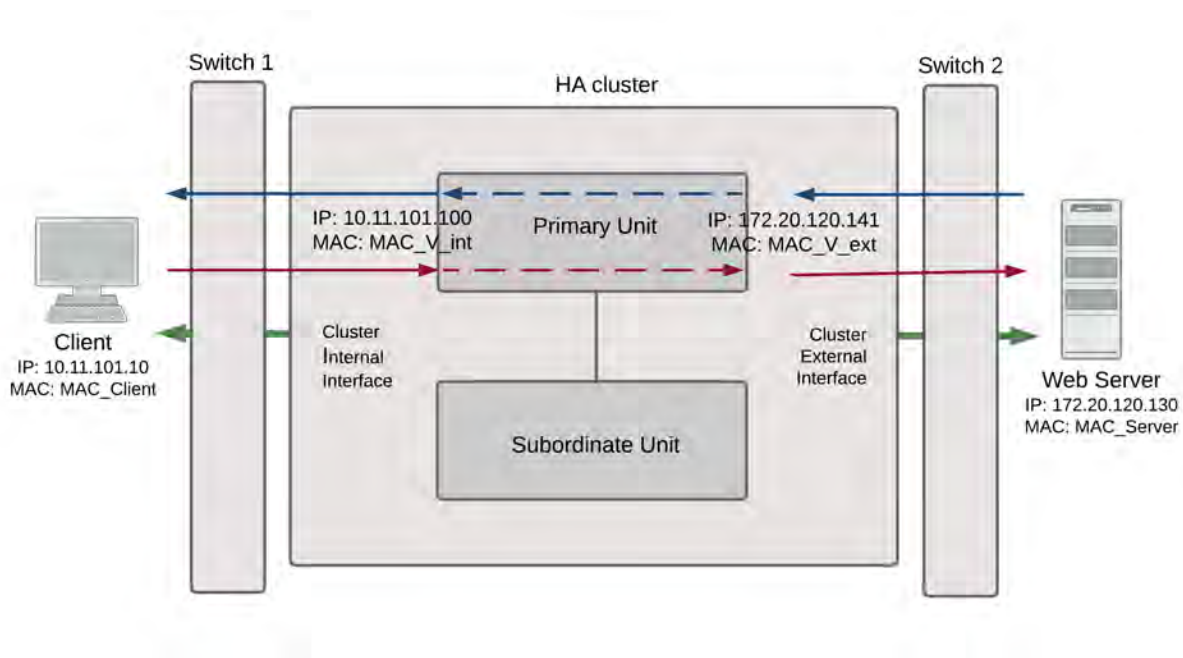

NAT mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in NAT mode. In the example, the NAT mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In an active-passive cluster operating in NAT mode, four MAC addresses are involved in communication between the client and the web server when the primary unit processes the connection:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),

In NAT mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only know the cluster external virtual MAC address (MAC_V_ext).

NAT mode active-passive packet flow**Packet flow from client to web server**

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_V_ext
Destination	172.20.120.130	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_V_int
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit becomes the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets from the internal interface to the 10.11.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.
If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Transparent mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the transparent mode cluster.

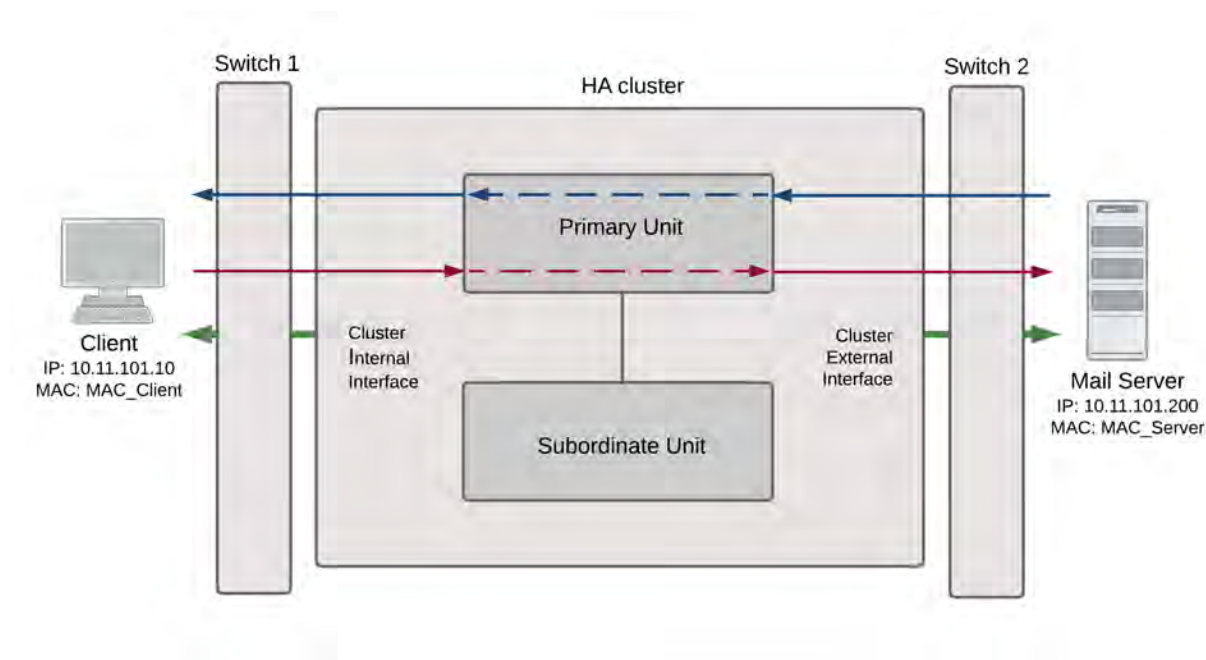

In an active-passive cluster operating in transparent mode, two MAC addresses are involved in the communication between a client and a server when the primary unit processes a connection:

- Client MAC address (MAC_Client)
- Server MAC address (MAC_Server)

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and processed by the cluster.

The cluster's presence on the network is transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the HA virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the HA virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-passive packet flow

Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary unit sends gratuitous ARP packets to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary unit sends gratuitous ARP packets to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.
If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Failover performance

This section describes the designed device and link failover times for a FortiGate cluster and also shows results of a failover performance test.

Device failover performance

By design FGCP device failover time is 2 seconds for a two-member cluster with ideal network and traffic conditions. If sub-second failover is enabled the failover time can drop below 1 second.

All cluster units regularly receive HA heartbeat packets from all other cluster units over the HA heartbeat link. If any cluster unit does not receive a heartbeat packet from any other cluster unit for 2 seconds, the cluster unit that has not sent heartbeat packets is considered to have failed.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions. Typically if sub-second failover is not enabled you can expect a failover time of 9 to 15 seconds depending on the cluster and network configuration. The failover time can also be increased by more complex configurations and or configurations with network equipment that is slow to respond.

You can change the `hb-lost-threshold` to increase or decrease the device failover time. See [Modifying heartbeat timing on page 1916](#) for information about using `hb-lost-threshold`, and other heartbeat timing settings.

Link failover performance

Link failover time is controlled by how long it takes for a cluster to synchronize the cluster link database. When a link failure occurs, the cluster unit that experienced the link failure uses HA heartbeat packets to broadcast the updated link database to all cluster units. When all cluster units have received the updated database the failover is complete.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions.

Reducing failover times

- Keep the network configuration as simple as possible with as few as possible network connections to the cluster.
- If possible operate the cluster in transparent mode.
- Use high-performance switches to that the switches failover to interfaces connected to the new primary unit as quickly as possible.
- Use accelerated FortiGate interfaces. In some cases accelerated interfaces will reduce failover times.
- Make sure the FortiGate sends multiple gratuitous arp packets after a failover. In some cases, sending more gratuitous arp packets will cause connected network equipment to recognize the failover sooner. To send 10 gratuitous arp packets:

```
config system ha
    set arps 10
end
```

- Reduce the time between gratuitous arp packets. This may also caused connected network equipment to recognize the failover sooner. To send 50 gratuitous arp packets with 1 second between each packet:

```
config system ha
    set arps 50
    set arps-interval 1
end
```

- Reduce the number of lost heartbeat packets and reduce the heartbeat interval timers to be able to more quickly detect a device failure. To set the lost heartbeat threshold to 3 packets and the heartbeat interval to 100 milliseconds:

```
config system ha
    set hb-interval 1
    set hb-lost-threshold 3
end
```

- Reduce the hello state hold down time to reduce the amount of the time the cluster waits before transitioning from the hello to the work state. To set the hello state hold down time to 5 seconds:

```
config system ha
    set hello-holddown 5
end
```

- Enable sending a link failed signal after a link failover to make sure that attached network equipment responds as quickly as possible to a link failure. To enable the link failed signal:

```
config system ha
    set link-failed-signal enable
end
```

Session failover (session-pickup)

Session failover means that after the primary unit fails, communications sessions resume on the new primary unit with minimal or no interruption. Two categories of sessions need to be resumed after a failover:

- Sessions passing through the cluster
- Sessions terminated by the cluster

If you enable session failover (also called session-pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables for sessions passing through the cluster, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

Session-pickup has some limitations. For example, session failover is not supported for sessions being scanned by proxy-based security profiles. Session failover is supported for sessions being scanned by flow-based security profiles; however, flow-based sessions that fail over are not inspected after they fail over. For more limitations, see [Session failover limitations for sessions passing through the cluster on page 1955](#).

Sessions terminated by the cluster include management sessions (such as HTTPS connections to the FortiGate GUI or SSH connection to the CLI as well as SNMP and logging and so on). Also included in this category are IPsec VPN, SSL VPN, sessions terminated by the cluster, explicit proxy, WAN Optimization and web caching. In general, whether or not session-pickup is enabled, these sessions do not failover and have to be restarted. There are some exceptions though, particularly for IPsec and SSL VPN. For more information, see [Session failover limitations for sessions terminated by the cluster on page 1958](#).

Enabling session-pickup for TCP, UDP, ICMP, and multicast session failover

To enable session-pickup, go to **System > HA** and enable session-pickup.

From the CLI enter:

```
config system ha
    set session-pickup enable
end
```

When session-pickup is enabled, the FGCP synchronizes the primary unit's TCP session table to all cluster units. As soon as a new TCP session is added to the primary unit session table, that session is synchronized to all cluster units. This synchronization happens as quickly as possible to keep the session tables synchronized.

If the primary unit fails, the new primary unit uses its synchronized session table to resume all TCP sessions that were being processed by the former primary unit with only minimal interruption. Under ideal conditions all TCP sessions should be resumed. This is not guaranteed though and under less than ideal conditions some TCP sessions may need to be restarted.

Enabling UDP and ICMP session failover

If session pickup is enabled, you can use the following command to also enable UDP and ICMP session failover:

```
config system ha
  set session-pickup-connectionless enable
end
```

Enabling multicast session failover

To configure multicast session failover, use the following command to change the multicast TTL timer to a smaller value than the default. The recommended setting to support multicast session failover is 120 seconds (2 minutes). The default setting is 600 seconds (10 minutes).

```
config system ha
  set multicast-ttl 120
end
```

The multicast TTL timer controls how long to keep synchronized multicast routes on the backup unit (so they are present on the backup unit when it becomes the new primary unit after a failover). If you set the multicast TTL lower the multicast routes on the backup unit are refreshed more often so are more likely to be accurate. Reducing this time causes route synchronization to happen more often and could affect performance.

If session pickup is disabled

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed. Most session can be resumed as a normal result of how TCP/IP communications resumes communication after any routine network interruption.

The session-pickup setting does not affect session failover for sessions terminated by the cluster.

If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage. Also if your cluster is mainly being used for traffic that is not synchronized (for example, for proxy-based security profile processing) enabling session pickup is not recommended since most sessions will not be failed over anyway.

If session pickup is not enabled, the FGCP does not synchronize the primary unit session table to other cluster units and sessions do not resume after a failover. After a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates.

Many protocols can successfully restart sessions with little, if any, loss of data. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Since most HTTP sessions are very short, in most cases they will not even notice an interruption unless they are downloading large files. Users downloading a large file may have to restart their download after a failover.

Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session-pickup. They include reducing the number of sessions that are synchronized by adding a session pickup delay and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

If session pickup is enabled, as soon as new sessions are added to the primary unit session table they are synchronized to the other cluster units. Enable the `session-pickup-delay` CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
    set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving session synchronization from the HA heartbeat interface reduces the bandwidth required for HA heartbeat traffic and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
    set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Session failover limitations for sessions passing through the cluster

This section contains information about session failover for communication sessions passing through the cluster. In general, if session pickup is enabled, session failover is supported for most TCP traffic. This section describes details about how this all works.

Protocol	Session Failover?
Most TCP sessions.	Supported if session-pickup is enabled. (More about TCP session failover on page 1956)
Multicast sessions	Supported if multicast session-pickup is enabled. (Enabling multicast session failover).
IPv6, NAT64, and NAT66	Supported if session-pickup is enabled.
Proxy-based security profile sessions	Not Supported, sessions have to be restarted. Proxy-based features require the FortiGate to maintain very large amounts of internal state information for each session. The FGCP does not synchronize this internal state information. As a result, proxy-based sessions are not failed over. Active-active clusters can resume some of these sessions after a failover. (Active-active HA subordinate units sessions can resume after a failover on page 1958)
Flow-based security profile sessions.	Supported if session-pickup is enabled. Flow-based sessions failover, but internal state information is not synchronized so sessions that fail over are no longer inspected by security profile functions. If both flow-based and proxy-based security profile features are applied to a TCP session, that session will not resume after a failover.
UDP and ICMP, or broadcast sessions	Supported if connectionless session-pickup is enabled. Otherwise, sessions have to be restarted. (UDP, ICMP, and broadcast packet session failover on page 1957)
GPRS Tunneling Protocol (GTP)	Supported with limitations. (FortiOS Carrier GTP session failover on page 1958)
SIP	Supported for active-passive HA only. (SIP session failover on page 1957)
SIMPLE, or SCCP signal session	Not supported, sessions have to be restarted.
SSL offloading and HTTP multiplexing	Not supported, sessions have to be restarted. (SSL offloading and HTTP multiplexing session failover on page 1958)

More about TCP session failover

TCP sessions that are not being processed by security profile features resume after a failover even if these sessions are accepted by security policies with security profiles. Only TCP sessions that are actually being processed by these security profile features do not resume after a failover. For example:

- TCP sessions that are not virus scanned, web filtered, spam filtered, content archived, or are not SIP, SIMPLE, or SCCP signal traffic resume after a failover, even if they are accepted by a security policy with security profile options enabled. For example, SNMP TCP sessions through the FortiGate resume after a failover because FortiOS does not apply any security profile options to SNMP sessions.
- TCP sessions for a protocol for which security profile features have not been enabled resume after a failover even if they are accepted by a security policy with security profile features enabled. For example, if you have not enabled any antivirus or content archiving settings for FTP, FTP sessions resume after a failover.

UDP, ICMP, and broadcast packet session failover

By default, even with session pickup enabled, the FGCP does not maintain a session table for UDP, ICMP, or broadcast packets. So the cluster does not specifically support failover of these packets.

Some UDP traffic can continue to flow through the cluster after a failover. This can happen if, after the failover, a UDP packet that is part of an already established communication stream matches a security policy. Then a new session will be created and traffic will flow. So after a short interruption, UDP sessions can appear to have failed over. However, this may not be reliable for the following reasons:

- UDP packets in the direction of the security policy must be received before reply packets can be accepted. For example, if a port1 -> port2 policy accepts UDP packets, UDP packets received at port2 destined for the network connected to port1 will not be accepted until the policy accepts UDP packets at port1 that are destined for the network connected to port2. So, if a user connects from an internal network to the Internet and starts receiving UDP packets from the Internet (for example streaming media), after a failover the user will not receive any more UDP packets until the user re-connects to the Internet site.
- UDP sessions accepted by NAT policies will not resume after a failover because NAT will usually give the new session a different source port. So only traffic for UDP protocols that can handle the source port changing during a session will continue to flow.

You can however, enable session pickup for UDP and ICMP packets by enabling session pickup for TCP sessions and then enabling session pickup for connectionless sessions:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

This configuration causes the cluster units to synchronize UDP and ICMP session tables and if a failover occurs UDP and ICMP sessions are maintained.

SIP session failover

If session pickup is enabled, the FGCP supports SIP session failover (also called stateful failover) for active-passive HA.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA failover occurs. But in most cases the call setup should be able to continue after the failover.

FortiOS Carrier GTP session failover

FortiOS Carrier HA supports GTP session failover. The primary unit synchronizes the GTP tunnel state to all cluster units after the GTP tunnel setup is completed. After the tunnel setup is completed, GTP sessions use UDP and HA does not synchronize UDP sessions to all cluster units. However, similar to other UDP sessions, after a failover, since the new primary unit will have the GTP tunnel state information, GTP UDP sessions using the same tunnel can continue to flow with some limitations.

The limitation on packets continuing to flow is that there has to be a security policy to accept the packets. For example, if the FortiOS Carrier unit has an internal to external security policy, GTP UDP sessions using an established tunnel that are received by the internal interface are accepted by the security policy and can continue to flow. However, GTP UDP packets for an established tunnel that are received at the external interface cannot flow until packets from the same tunnel are received at the internal interface.

If you have bi-directional policies that accept GTP UDP sessions then traffic in either direction that uses an established tunnel can continue to flow after a failover without interruption.

SSL offloading and HTTP multiplexing session failover

SSL offloading and HTTP multiplexing are both enabled from firewall virtual IPs and firewall load balancing. Similar to the features applied by security profile, SSL offloading and HTTP multiplexing requires the FortiGate to maintain very large amounts of internal state information for each session. Sessions accepted by security policies containing virtual IPs or virtual servers with SSL offloading or HTTP multiplexing enabled do not resume after a failover.

Active-active HA subordinate units sessions can resume after a failover

In an active-active cluster, subordinate units process sessions. After a failover, all cluster units that are still operating may be able to continue processing the sessions that they were processing before the failover. These sessions are maintained because after the failover the new primary unit uses the HA session table to continue to send session packets to the cluster units that were processing the sessions before the failover. Cluster units maintain their own information about the sessions that they are processing and this information is not affected by the failover. In this way, the cluster units that are still operating can continue processing their own sessions without loss of data.

The cluster keeps processing as many sessions as it can. But some sessions can be lost. Depending on what caused the failover, sessions can be lost in the following ways:

- A cluster unit fails (the primary unit or a subordinate unit). All sessions that were being processed by that cluster unit are lost.
- A link failure occurs. All sessions that were being processed through the network interface that failed are lost.

This mechanism for continuing sessions is not the same as session failover because:

- Only the sessions that can be maintained are maintained.
- The sessions are maintained on the same cluster units and not re-distributed.
- Sessions that cannot be maintained are lost.

Session failover limitations for sessions terminated by the cluster

This section contains information about session failover for communication sessions terminated by the cluster. Sessions terminated by the cluster include management sessions as well as IPsec and SSL VPN, WAN Optimization and so on between the cluster and a client.

In general, most sessions terminated by the cluster have to be restarted after a failover. There are some exceptions though, for example, the FGCP provides failover for IPsec and SSL VPN sessions terminated by the cluster.

The session pickup setting does not affect session failover for sessions terminated by the cluster. Also other cluster settings such as active-active or active-passive mode do not affect session failover for sessions terminated by the cluster.

Protocol	Session Failover?
Administrative or management connections such as connecting to the GUI or CLI, SNMP, syslog, communication with FortiManager, FortiAnalyzer and so on.	Not supported, sessions have to be restarted.
Explicit web proxy, WCCP, WAN Optimization and Web Caching.	Not supported, sessions have to be restarted. (Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and Web Caching session failover on page 1959)
IPsec VPN tunnels terminating at the FortiGate	Supported. SAs and related IPsec VPN tunnel data is synchronized to cluster members. (Synchronizing IPsec VPN SAs on page 1960)
SSL VPN tunnels terminating at the FortiGate	Partially supported. Sessions are not synchronized and have to be restarted. Authentication failover and cookie failover is supported for SSL VPN web mode sessions. Authentication failover is not supported for FortiClient SSL VPN sessions. (SSL VPN session failover and SSL VPN authentication failover on page 1960)
PPTP and L2TP VPN terminating at the FortiGate	Not supported, sessions have to be restarted.

Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and Web Caching session failover

Explicit web proxy, explicit FTP proxy, WCCP, WAN optimization and web caching sessions all require the FortiGate to maintain very large amounts of internal state information for each session. This information is not maintained and these sessions do not resume after a failover.

The active-passive HA clustering is recommended for WAN optimization. All WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

Also, Web cache and byte cache databases are only stored on the primary unit. These databases are not synchronized to the cluster. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGates that it is participating with in WAN optimization tunnels.

SSL VPN session failover and SSL VPN authentication failover

Session failover is not supported for SSL VPN tunnels. However, authentication failover is supported for SSL VPN web mode sessions. This means that after a failover, SSL VPN web mode sessions can re-establish the SSL VPN session between the SSL VPN client and the FortiGate without having to authenticate again.

Authentication failover is not supported for FortiClient SSL VPN sessions.

All sessions inside the SSL VPN tunnel that were running before the failover are stopped and have to be restarted. For example, file transfers that were in progress would have to be restarted. As well, any communication sessions with resources behind the FortiGate that are started by an SSL VPN session have to be restarted.

To support SSL VPN cookie failover, when an SSL VPN session starts, the FGCP distributes the cookie created to identify the SSL VPN session to all cluster units.

PPTP and L2TP VPN sessions

PPTP and L2TP VPNs are supported in HA mode. For a cluster you can configure PPTP and L2TP settings and you can also add security policies to allow PPTP and L2TP pass through. However, the FGCP does not provide session failover for PPTP or L2TP. After a failover, all active PPTP and L2TP sessions are lost and must be restarted.

Synchronizing IPsec VPN SAs

The FGCP synchronizes IPsec security associations (SAs) between cluster members so that if a failover occurs, the cluster can resume IPsec sessions without having to establish new SAs. The result is improved failover performance because IPsec sessions are not interrupted to establish new SAs. Also, establishing a large number of SAs can reduce cluster performance.

The FGCP implements slightly different synchronization mechanisms for IKEv1 and IKEv2.

Synchronizing SAs for IKEv1

When an SA is synchronized to the subordinate units, the sequence number is set to the maximum sequence number. After a failover, all inbound traffic that connects with the new primary unit and uses the SA will be accepted without needing to re-key. However, first outbound packet to use the SA causes the sequence number to overflow and so causes the new primary unit to re-key the SA.

Please note the following:

- The cluster synchronizes all IPsec SAs.
- IPsec SAs are not synchronized until the IKE process has finished synchronizing the ISAKMP SAs. This is required in for dialup tunnels since it is the synchronizing of the ISAKMP SA that creates the dialup tunnel.
- A dialup interface is created as soon as the phase 1 is complete. This ensures that the when HA synchronizes phase 1 information the dialup name is included.
- If the IKE process re-starts for any reason it deletes any dialup tunnels that exist. This forces the peer to re-key them.
- IPsec SA deletion happens immediately. Routes associated with a dialup tunnel that is being deleted are cleaned up synchronously as part of the delete, rather than waiting for the SA hard-expiry.
- The FGCP does not sync the IPsec tunnel MTU from the primary unit to the subordinate units. This means that after HA failover if the first packet received by the FortiGate arrives after the HA route has been deleted and before the new route is added and the packet is larger than the default MTU of 1024 then the FortiGate sends back an

ICMP fragmentation required. However, as soon as routing is re-established then the MTU will be corrected and traffic will flow.

Synchronizing SAs for IKEv2

Due to the way the IKEv2 protocol is designed the FGCP cannot use exactly the same solution that is used for synchronizing IKEv1 SAs, though it is similar.

For IKEv2, like IKEv1, the FGCP synchronizes IKE and ISAKMP SAs from the primary unit to the subordinate units. However, for IKEv2 the FGCP cannot actually use this IKE SA to send/receive IKE traffic because IKEv2 includes a sequence number in every IKE message and thus it would require synchronizing every message to the subordinate units to keep the sequence numbers on the subordinate units up to date.

Instead, the FGCP synchronizes IKEv2 Message IDs. This Message ID Sync allows IKEv2 to re-negotiate send and receive message ID counters after a failover. By doing this, the established IKE SA can remain up, instead of re-negotiating.

The `diagnose vpn ike stats` command shows statistics for the number of HA messages sent/received for IKEv2. The output of this command includes a number of fields prefixed with `ha` that contain high availability related-data. For example:

```
.  
.   
.   
ha.resync: 0  
ha.vike.sync: 0  
ha.conn.sync: 0  
ha.sync.tx: 1  
ha.sync.rx: 0  
ha.sync.rx.len.bad: 0  
.   
.   
.
```

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

In a cluster, the primary unit only stores web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGates that it is participating with in WAN optimization tunnels.

HA and load balancing

FGCP active-active (a-a) load balancing distributes network traffic among all of the units in a cluster. Load balancing can improve cluster performance because the processing load is shared among multiple cluster units.

This chapter describes how active-active load balancing works and provides detailed active-active HA NAT and transparent mode packet flow descriptions.

Load balancing overview

FGCP active-active HA uses a technique similar to unicast load balancing in which the primary unit is associated with the cluster HA virtual MAC addresses and cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit then uses a load balancing schedule to distribute sessions to all of the units in the cluster (including the primary unit). Subordinate unit interfaces retain their actual MAC addresses and the primary unit communicates with the subordinate units using these MAC addresses. Packets exiting the subordinate units proceed directly to their destination and do not pass through the primary unit first.

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Proxy-based security profile processing that is load balanced includes proxy-based virus scanning, proxy-based web filtering, proxy-based email filtering, and proxy-based data leak prevention (DLP) of HTTP, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, and NNTP, sessions accepted by security policies.

Other features enabled in security policies such as Endpoint security, traffic shaping and authentication have no effect on active-active load balancing.

You can also enable `load-balance-all` to have the primary unit load balance all TCP sessions. Load balancing TCP sessions increases overhead and may actually reduce performance so it is disabled by default. You can also enable `load-balance-udp` to have the primary unit load balance all UDP sessions. Load balancing UDP sessions also increases overhead so it is also disabled by default.

NP4 and NP6 processors can also offload and accelerate load balancing.

During active-active HA load balancing the primary unit uses the configured load balancing schedule to determine the cluster unit that will process a session. The primary unit stores the load balancing information for each load balanced session in the cluster load balancing session table. Using the information in this table, the primary unit can then forward all of the remaining packets in each session to the appropriate cluster unit. The load balancing session table is synchronized among all cluster units.

HTTPS, ICMP, multicast, and broadcast sessions are never load balanced and are always processed by the primary unit. IPS, Application Control, flow-based virus scanning, flow-based web filtering, flow-based DLP, flow-based email filtering, VoIP, IM, P2P, IPsec VPN, HTTPS, SSL VPN, HTTP multiplexing, SSL offloading, WAN optimization, explicit web proxy, and WCCP sessions are also always processed only by the primary unit.

In addition to load balancing, active-active HA also provides the same session, device and link failover protection as active-passive HA. If the primary unit fails, a subordinate unit becomes the primary unit and resumes operating the cluster.

Active-active HA also maintains as many load balanced sessions as possible after a failover by continuing to process the load balanced sessions that were being processed by the cluster units that are still operating. See [Active-active HA subordinate units sessions can resume after a failover on page 1958](#) for more information.

Load balancing schedules

The load balancing schedule controls how the primary unit distributes packets to all cluster units. You can select from the following load balancing schedules.

Schedule	Description
None	No load balancing. Select None when the cluster interfaces are connected to load balancing switches. If you select None, the Primary unit does not load balance traffic and the subordinate units process incoming traffic that does not come from the Primary unit. For all other load balancing schedules, all traffic is received first by the Primary unit, and then forwarded to the subordinate units. The subordinate units only receive and process packets sent from the primary unit.
Hub	Load balancing if the cluster interfaces are connected to a hub. Traffic is distributed to cluster units based on the source IP and destination IP of the packet.
Least-Connection	If the cluster units are connected using switches, select Least Connection to distribute network traffic to the cluster unit currently processing the fewest connections.
Round-Robin	If the cluster units are connected using switches, select Round-Robin to distribute network traffic to the next available cluster unit.
Weighted Round-Robin	Similar to round robin, but weighted values are assigned to each of the units in a cluster based on their capacity and on how many connections they are currently processing. For example, the primary unit should have a lower weighted value because it handles scheduling and forwards traffic. Weighted round robin distributes traffic more evenly because units that are not processing traffic will be more likely to receive new connections than units that are very busy.
Random	If the cluster units are connected using switches, select Random to randomly distribute traffic to cluster units.
IP	Load balancing according to IP address. If the cluster units are connected using switches, select IP to distribute traffic to units in a cluster based on the source IP and destination IP of the packet.
IP Port	Load balancing according to IP address and port. If the cluster units are connected using switches, select IP Port to distribute traffic to units in a cluster based on the source IP, source port, destination IP, and destination port of the packet.

Once a packet has been propagated to a subordinate unit, all packets are part of that same communication session are also propagated to that same subordinate unit. Traffic is distributed according to communication session, not just according to individual packet.

Any subordinate unit that receives a forwarded packet processes it, without applying load balancing. Note that subordinate units are still considered to be active, because they perform routing, virus scanning, and other

FortiGate tasks on their share of the traffic. Active subordinate units also share their session and link status information with all cluster units. The only things that active members do not do is make load balancing decisions.

Even though the primary unit is responsible for the load balancing process, the primary unit still acts like a FortiGate in that it processes packets, performing, routing, firewall, virus scanning, and other FortiGate tasks on its share of the traffic. Depending on the load balancing schedule used, the primary unit may assign itself a smaller share of the total load.

More about active-active failover

If a subordinate unit fails, the primary unit re-distributes the sessions that the subordinate was processing among the remaining active cluster members. If the primary unit fails, the subordinate units negotiate to select a new primary unit. The new primary unit continues to distribute packets among the remaining active cluster units.

Failover works in a similar way if the cluster consists of only two units. If the primary unit fails the subordinate unit negotiates and becomes the new primary unit. If the subordinate unit fails, the primary unit processes all traffic. In both cases, the single remaining unit continues to function as a primary unit, maintaining the HA virtual MAC address for all of its interfaces.

HTTPS sessions, active-active load balancing, and proxy servers

To prevent HTTPS web filtering problems active-active HA does not load balance HTTPS sessions. The FortiGate identifies HTTPS sessions as all sessions received on the HTTPS TCP port. The default HTTPS port is 443. You can go to **Policy & Objects > Policy > SSL/SSH Inspection** to use a custom port for HTTPS sessions. If you change the HTTPS port, the FGCP stops load balancing all sessions that use the custom HTTPS port.

Normally you would not change the HTTPS port. However, if your network uses a proxy server for HTTPS traffic you may have to change to the custom HTTPS port used by your proxy server. If your network uses a proxy server you might also use the same port for both HTTP and HTTPS traffic. In this case you would configure the FortiGate to use custom ports for both HTTP and HTTPS traffic. Go to **Policy & Objects > Policy > Proxy Options** to use a custom port for HTTP.

Using the same port for HTTP and HTTPS traffic can cause problems with active-active clusters because active-active clusters always load balance HTTP traffic. If both HTTP and HTTPS use the same port, the active-active cluster cannot differentiate between HTTP and HTTPS traffic and will load balance both.

As mentioned above, load balancing HTTPS traffic may cause problems with HTTPS web filtering. To avoid this problem, you should configure your proxy server to use different ports for HTTP and HTTPS traffic. Then configure your cluster to also use different ports for HTTP and HTTPS.

Selecting a load balancing schedule

You can select the load balancing schedule when initially configuring the cluster and you can change the load balancing schedule at any time while the cluster is operating without affecting cluster operation.

You can select a load balancing schedule from the CLI. Use the following command to select a load balancing schedule:

```
config system ha
  set schedule {hub | ip | ipport | leastconnection | none | random | round-robin
              | weight-round-robin}
end
```

Load balancing TCP and UDP sessions

You can use the following command to configure the cluster to load balance TCP sessions in addition to security profile sessions.

```
config system ha
    set load-balance-all enable
end
```

Enabling `load-balance-all` to add load balancing of TCP sessions may not improve performance because the cluster requires additional overhead to load balance sessions. Load balancing a TCP session usually requires about as much overhead as just processing it. On the other hand, TCP load balancing performance may be improved if your FortiGate includes NP4 or NP6 processors.

You can enable `load-balance-all` and monitor network performance to see if it improves. If performance is not improved, you might want to change the HA mode to active-passive since active-active HA is not providing any benefit.

On some FortiGate models you can use the following command to also load balance UDP sessions:

```
config system ha
    set load-balance-udp enable
end
```

Similar to load balancing TCP sessions, load balancing UDP sessions may also not improve performance. Also UDP load balancing performance may be improved with NP4 and NP6 processors.

Using NP4 or NP6 processors to offload load balancing

FortiGates that include NP4 and NP6 network processors can provide hardware acceleration for active-active HA cluster by offloading load balancing from the primary unit CPU. Network processors are especially useful when load balancing TCP and UDP sessions.

The first packet of every new session is received by the primary unit and the primary unit uses its load balancing schedule to select the cluster unit that will process the new session. This information is passed back to the network processor and all subsequent packets of the same sessions are offloaded to the network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the network processor resulting in a faster and more stable active-active cluster.

To take advantage of network processor load balancing acceleration, connect the cluster unit interfaces with network processors to the busiest networks. Connect other interfaces to less busy networks. No special FortiOS or HA configuration is required. Network processor acceleration of active-active HA load balancing is supported for any active-active HA configuration or active-active HA load balancing schedule.

Configuring weighted-round-robin weights

You can configure weighted round-robin load balancing for a cluster and configure the static weights for each of the cluster units according to their priority in the cluster. When you set `schedule` to `weight-round-robin` you can use the `weight` option to set the static weight of each cluster unit. The static weight is set according to the priority of each unit in the cluster. A FortiGate HA cluster can contain up to four FortiGates so you can set up to 4 static weights.

The priority of a cluster unit is determined by its device priority, the number of monitored interfaces that are functioning, its age in the cluster and its serial number. Priorities are used to select a primary unit and to set the priorities of all of the subordinate units. Thus the priority of a cluster unit can change depending on configuration

settings, link failures and so on. Since weights are also set using this priority, the weights are independent of specific cluster units but do depend on the role of the each unit in the cluster.

You can use the following command to display the relative priorities of the units in a cluster. The cluster unit serial numbers and their priorities are listed in the last few lines of the command output. This example shows a cluster of three FortiGates:

```
get system ha status
.
.
.
Slave : FG-5KD3914800284, operating cluster index = 1
Master: FG-5KD3914800344, operating cluster index = 0
Slave : FG-5KD3914800353, operating cluster index = 2
```

The primary unit always has the highest priority and the subordinate units have lower priorities.

The default static weight for each cluster unit is 40. This means that sessions are distributed evenly among all cluster units. You can use the `set weight` command to change the static weights of cluster units to distribute sessions to cluster units depending on their priority in the cluster. The weight can be between 0 and 255. Increase the weight to increase the number of connections processed by the cluster unit with that priority.

You set the weight for each unit separately. For the example cluster of 3 FortiGates you can set the weight for each unit as follows:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set weight 0 5
  set weight 1 10
  set weight 2 15
end
```

If you enter the `get` command to view the HA configuration the output for `weight` would be:

```
weight 5 10 15 40 40 40 40 40 40 40 40 40 40 40 40
```

This configuration has the following results if the output of the `get system ha status` command is that shown above:

- The first five connections are processed by the primary unit (priority 0, weight 5).
- The next 10 connections are processed by the first subordinate unit (priority 1, weight 10)
- The next 15 connections are processed by the second subordinate unit (priority 2, weight 15)

Dynamically optimizing weighted load balancing according to how busy cluster units are

In conjunction with using static weights to load balance sessions among cluster units you can configure a cluster to dynamically load balance sessions according to individual cluster unit CPU usage, memory usage, and number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy-based security profile sessions. If any of these system loading indicators increases above configured thresholds, weighted load balancing dynamically sends fewer new sessions to the busy unit until it recovers.

High CPU or memory usage indicates that a unit is under increased load and may not be able to process more sessions. HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy use are also good indicators of how busy a cluster unit is, since processing high numbers of these proxy sessions can quickly reduce overall cluster unit performance.

For example, you can set a CPU usage high watermark threshold. When a cluster unit reaches this high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to the low watermark threshold. When the low watermark threshold is reached the cluster resumes normal load balancing of sessions to the cluster unit.

You can set individual high and low watermark thresholds and weights for CPU usage, memory usage, and for the number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions.

The CPU usage, memory usage, and proxy weights determine how the cluster load balances sessions when a high watermark threshold is reached and also affect how the cluster load balances sessions when multiple cluster units reach different high watermark thresholds at the same time. For example, you might be less concerned about a cluster unit reaching the memory usage high watermark threshold than reaching the CPU usage high watermark threshold. If this is the case you can set the weight lower for memory usage. Then, if one cluster unit reaches the CPU usage high watermark threshold and a second cluster unit reaches the memory usage high watermark threshold the cluster will load balance more sessions to the cluster unit with high memory usage and fewer sessions to the cluster unit with high CPU usage. As a result, reaching the CPU usage high watermark will have a greater affect on how sessions are redistributed than reaching the memory usage high watermark.

When a high watermark threshold is reached, the corresponding weight is subtracted from the static weight of the cluster unit. The lower the weight the fewer the number of sessions that are load balanced to that unit.

Subsequently when the low watermark threshold is reached, the static weight of the cluster unit returns to its configured value. For the weights to all be effective the weights assigned to the load indicators should usually be lower than or equal to the static weights assigned to the cluster units.

Use the following command to set thresholds and weights for CPU and memory usage and HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold <weight> <low> <high>
  set memory-threshold <weight> <low> <high>
  set http-proxy-threshold <weight> <low> <high>
  set ftp-proxy-threshold <weight> <low> <high>
  set imap-proxy-threshold <weight> <low> <high>
  set nntp-proxy-threshold <weight> <low> <high>
  set pop3-proxy-threshold <weight> <low> <high>
  set smtp-proxy-threshold <weight> <low> <high>
end
```

For each option, the weight range is 0 to 255 and the default weight is 5. The low and high watermarks are a percent (0 to 100). The default low and high watermarks are 0 which means they are disabled. The default configuration when weighted load balancing is enabled looks like the following:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold 5 0 0
  set memory-threshold 5 0 0
  set http-proxy-threshold 5 0 0
  set ftp-proxy-threshold 5 0 0
  set imap-proxy-threshold 5 0 0
  set nntp-proxy-threshold 5 0 0
  set pop3-proxy-threshold 5 0 0
  set smtp-proxy-threshold 5 0 0
end
```

When you first enable HA weighted load balancing, the weighted load balancing configuration is synchronized to all cluster units and each cluster unit has the default configuration shown above. Changes to the CPU, memory, HTTP, FTP, IMAP, NNTP, POP3, and SMTP proxy thresholds and low and high watermarks must be made for each cluster unit and are not synchronized to the other cluster units.

When you configure them, the high watermarks must be greater than their corresponding low watermarks.

For CPU and memory usage the low and high watermarks are compared with the percentage CPU and memory use of the cluster unit. For each of the proxies the high and low watermarks are compared to a number that represents percent of the max number of proxy sessions being used by a proxy. This number is calculated using the formula:

$$\text{proxy usage} = (\text{current sessions} * 100) / \text{max sessions}$$

where:

`current sessions` is the number of active sessions for the proxy type.

`max sessions` is the session limit for the proxy type. The session limit depends on the FortiGate and its configuration.

You can use the following command to display the maximum and current number of sessions for a proxy:

```
get test {ftpd | http | imap | nntp | pop3 | smtp} 4
```

You can use the following command to display the maximum number of sessions and the and current number of sessions for all of the proxies:

```
get test proxyworker 4
```

The command output includes lines similar to the following:

```
get test http 4
HTTP Common
Current Connections          5000/8032
```

In the example, 5000 is the current number of proxy connections being used by HTTP and 8032 is the maximum number of proxy sessions allowed. For this example the proxy usage would be:

```
proxy usage = (5000 * 100) / 8032
proxy usage = 62%
```

Example weighted load balancing configuration

Consider a cluster of three FortiGates with host names FGT_ha_1, FGT_ha_2, and FGT_ha_3 as shown below. This example describes how to configure weighted load balancing settings for CPU and memory usage for the cluster and then to configure HTTP and POP3 proxy weights to send most HTTP and POP3 proxy sessions to different cluster units.

Example HA weighted load balancing configuration

Connect to the cluster CLI and use the following command to set the CPU usage threshold weight to 30, low watermark to 60, and high watermark to 80. This command also sets the memory usage threshold weight to 10, low watermark to 60, and high watermark to 90.

```

config system ha
    set mode a-a
    set schedule weight-round-robin
    set cpu-threshold 30 60 80
    set memory-threshold 10 60 90
end
  
```

The static weights for the cluster units remain at the default values of 40. Since this command changes the mode to `a-a` and the schedule to `weight-round-robin` for the first time, the weight settings are synchronized to all cluster units.

As a result of this configuration, if the CPU usage of any cluster unit (for example, FGT_ha_1) reaches 80% the static weight for that cluster unit is reduced from 40 to 10 and only 10 of every 120 new sessions are load balanced to this cluster unit. If the memory usage of FGT_ha_1 also reaches 90% the static weight further reduces to 0 and no new sessions are load balanced to FGT_ha_1. Also, if the memory usage of FGT_ha_2 reaches 90% the static weight of FGT_ha_2 reduces to 30 and 30 of every 120 new sessions are load balanced to FGT_ha_2.

Now that you have established the weight load balancing configuration for the entire cluster you can monitor the cluster to verify that processing gets distributed evenly to all cluster units. From the GUI you can go to **System > HA > View HA Statistics** and see the CPU usage, active sessions, memory usage and other statistics for all of the cluster units. If you notice that one cluster unit is more or less busy than others you can adjust the dynamic weights separately for each cluster unit.

For example, in some active-active clusters the primary unit may tend to be busier than other cluster units because in addition to processing sessions the primary unit also receives all packets sent to the cluster and performs load balancing to distribute the sessions to other cluster units. To reduce the load on the primary unit you could reduce the CPU and memory usage high watermark thresholds for the primary unit so that fewer sessions are distributed to the primary unit. You could also reduce the primary unit's high watermark setting for the proxies to distribute more proxy sessions to other cluster units.

This would only be useful if you are using device priorities and override settings to make sure the same unit always becomes the primary unit. See [Controlling primary unit selection using device priority and override on page 1754](#).

If the example cluster is configured for FGT_ha_2 to be the primary unit, connect to the FGT_ha_2's CLI and enter the following command to set CPU usage, memory usage, and proxy usage high watermark thresholds lower.

```
config system ha
  set cpu-threshold 30 60 70
  set memory-threshold 30 60 70
  set http-proxy-threshold 30 60 70
  set ftp-proxy-threshold 30 60 70
  set imap-proxy-threshold 30 60 70
  set nntp-proxy-threshold 30 60 70
  set pop3-proxy-threshold 30 60 70
  set smtp-proxy-threshold 30 60 70
end
```

As a result, when any of these factors reaches 70% on the primary unit, fewer sessions will be processed by the primary unit, preventing the number of sessions being processed from rising.

NAT mode active-active cluster packet flow

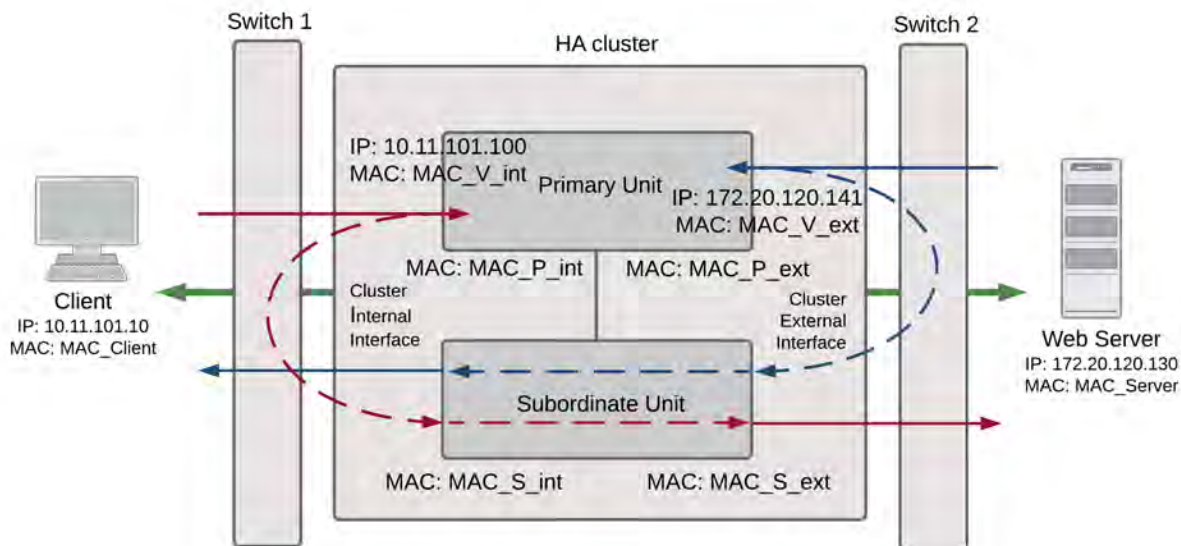

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in NAT mode. In the example, the NAT mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In NAT mode, eight MAC addresses are involved in active-active communication between the client and the web server when the primary unit load balances packets to the subordinate unit:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

In NAT mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only knows the cluster external virtual MAC address (MAC_V_ext).

NAT mode active-active packet flow

Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

IP address	MAC address
------------	-------------

Source	10.11.101.10	MAC_P_int
Destination	172.20.120.130	MAC_S_int

7. The subordinate unit recognizes that the packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_S_ext
Destination	172.20.120.130	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_P_ext
Destination	172.20.120.141	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets to the 10.10.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 network to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

Transparent mode active-active cluster packet flow

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the transparent mode cluster.

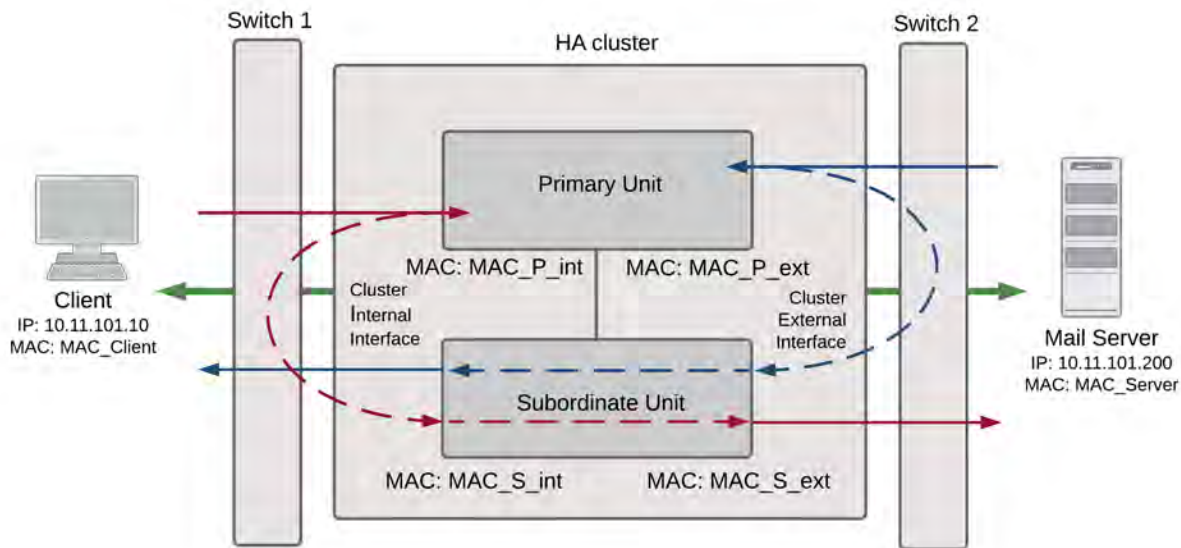

In transparent mode, six MAC addresses are involved in active-active communication between a client and a server when the primary unit load balances packets to the subordinate unit:

- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and load balanced among cluster members.

The cluster's presence on the network and its load balancing are transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the external virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the internal virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-active packet flow

Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	10.11.101.200	MAC_S_int

7. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_S_ext
Destination	10.11.101.200	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_P_ext
Destination	10.11.101.10	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary unit sends gratuitous ARP requests to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary unit sends gratuitous ARP requests to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

HA with FortiGate-VM and third-party products

This chapter provides information about operating FortiOS VM cluster and operating FortiGate clusters with third party products such as layer-2 and layer-3 switches.

FortiGate-VM for VMware HA configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGCP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8893. All synchronization activity takes place over the HA heartbeat link using TCP/703 and UDP/703 packets. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect heartbeat interfaces.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect FortiGate VM interfaces.
4. Set **MAC Address Changes** to **Accept**.
5. Set **Forged Transmits** to **Accept**.

FortiGate VM for Hyper-V HA configuration

Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC

spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

Troubleshooting layer-2 switches

Issues may occur because of the way an HA cluster assigns MAC addresses to the primary unit. Two clusters with the same group ID cannot connect to the same switch and cannot be installed on the same network unless they are separated by a router.

Forwarding delay on layer 2 switches

You must ensure that if there is a switch between the FortiGate HA cluster and the network it is protecting and the switch has a forwarding delay (even if spanning tree is disabled) when one of its interfaces is activated then the forwarding delay should be set as low as possible. For example, some versions of Cisco IOS have a forwarding delay of 15 seconds even when spanning tree is disabled. If left at this default value then TCP session pickup can fail because traffic is not forwarded through the switch on HA failover.

Failover issues with layer-3 switches

After a failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables of the switches connected to the cluster. If the cluster is connected using layer-2 switches, the MAC forwarding tables (also called arp tables) are refreshed by the gratuitous ARP packets and the switches start directing packets to the new primary unit.

In some configurations that use layer-3 switches, after a failover, the layer-3 switches may not successfully re-direct traffic to the new primary unit. The possible reason for this is that the layer-3 switch might keep a table of IP addresses and interfaces and may not update this table for a relatively long time after the failover (the table is not updated by the gratuitous ARP packets). Until the table is updated, the layer-3 switch keeps forwarding packets to the now failed cluster unit. As a result, traffic stops and the cluster does not function.

As of the release date of this document, Fortinet has not developed a workaround for this problem. One possible solution would be to clear the forwarding table on the layer-3 switch.

The `config system ha link-failed-signal` command described in [Updating MAC forwarding tables when a link failover occurs on page 1940](#) can be used to resolve link failover issues similar to those described here.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Ethertype conflicts with third-party switches

Some third-party network equipment may use packets with Ethertypes that are the same as the ethertypes used for HA heartbeat packets. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 heartbeat packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGates connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

You can also use the following CLI commands to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For more information, see [Heartbeat packet Ethertypes on page 1915](#).

LACP, 802.3ad aggregation and third-party switches

If a cluster contains 802.3ad aggregated interfaces you should connect the cluster to switches that support configuring multiple Link Aggregation (LAG) groups.

The primary and subordinate unit interfaces have the same MAC address, so if you cannot configure multiple LAG groups a switch may place all interfaces with the same MAC address into the same LAG group; disrupting the operation of the cluster.

You can change the FortiGate configuration to prevent subordinate units from participating in LACP negotiation. For example, use the following command to do this for an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

This configuration prevents the subordinate unit interfaces from sending or receiving packets. Resulting in the cluster not being able to operate in active-active mode. As well, failover may be slower because after a failover the new primary unit has to perform LACP negotiation before being able to process network traffic.

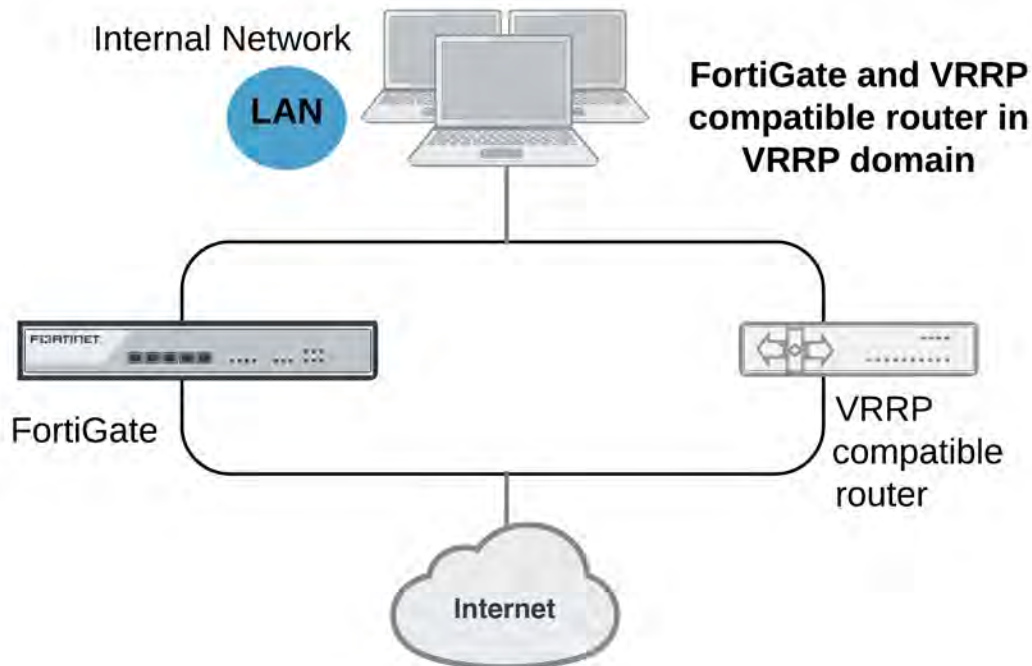

For more information, see [FGCP HA with 802.3ad aggregated interfaces on page 1823](#).

VRRP high availability

A Virtual Router Redundancy Protocol (VRRP) configuration can be used as a high availability solution to make sure that a network maintains connectivity with the internet (or with other networks) even if the default router for the network fails. Using VRRP, if a router or a FortiGate fails, all traffic to this router transparently fails over to another router or FortiGate that takes over the role of the router or FortiGate that failed. If the failed router or FortiGate is restored, it will once again take over processing traffic for the network. VRRP is described by [RFC 3768](#).

FortiOS supports VRRP versions 2 and 3 and you can set up VRRP domains that include multiple FortiGates and other VRRP-compatible routers. You can add different FortiGate models to the same VRRP domain. FortiOS supports IPv4 VRRP and you can add IPv4 VRRP virtual routers to the same interface. FortiGates can also be quickly and easily integrated into a network that has already deployed a group of routers using VRRP.

Example VRRP configuration

The most common application of VRRP is to provide redundant default routers between an internal network and the internet. The default routers can be FortiGates and or any routers that support VRRP.

To set up VRRP:

1. Add a virtual VRRP router to the internal interface of each of the FortiGates and routers. This adds the FortiGates and routers to the same VRRP domain.
2. Set the VRRP IP address of the domain to the internal network default gateway IP address.

3. Give one of the VRRP domain members the highest priority so it becomes the primary (or master) router and give the others lower priorities so they become backup routers.

During normal operations, all traffic from the internal network to the internet passes through the primary VRRP router. The primary router also sends VRRP advertisement messages to the backup routers. A backup router will not attempt to become a primary router while receiving these messages. If the primary router fails, the backup router with the highest priority becomes the new primary router after a short delay. During this delay the new primary router sends gratuitous ARP packets to the network to map the network's default route IP address to the new primary router's MAC address. All packets sent to the default route are now sent the new primary router. If the new primary router is a FortiGate, the network continues to benefit from FortiOS security features. If the new primary router is just a router, traffic continues to flow, but FortiOS security features are unavailable until the FortiGate is back on line.

If the backup router is a FortiGate, during a VRRP failover, as the FortiGate begins operating as the new primary router it will not have session information for all of the failed over in-progress sessions. So it would normally not be able to forward in-progress session traffic. To resolve this problem, immediately after a failover and for a short time (called the start time) the FortiGate acting as the new primary router operates with asymmetric routing enabled. This allows it to re-create all of the in-progress sessions and add them to its session table.

While operating with asymmetric routing enabled, the FortiGate cannot apply security functions. When the start-time ends the FortiGate disables asymmetric routing and returns to normal operation (including applying security functions).

During normal operations, all traffic from the internal network to the Internet passes through the primary VRRP router. The primary router also sends VRRP advertisement messages to the backup routers. A backup router will not attempt to become a primary router while receiving these messages. If the primary router fails, the backup router with the highest priority becomes the new primary router after a short delay. During this delay the new primary router sends gratuitous ARP packets to the network to map the network's default route IP address to the new primary router's MAC address. All packets sent to the default route are now sent the new primary router. If the new primary router is a FortiGate, the network continues to benefit from FortiOS security features. If the new primary router is just a router, traffic continues to flow, but FortiOS security features are unavailable until the FortiGate is back on line.

If the backup router is a FortiGate, during a VRRP failover, as the FortiGate begins operating as the new primary router it will not have session information for all of the failed over in-progress sessions. So it would normally not be able to forward in-progress session traffic. To resolve this problem, immediately after a failover and for a short time (called the start time) the FortiGate acting as the new primary router operates with asymmetric routing enabled. This allows it to re-create all of the in-progress sessions and add them to its session table.

While operating with asymmetric routing enabled, the FortiGate cannot apply security functions. When the start-time ends the FortiGate disables asymmetric routing and returns to normal operation (including applying security functions).

Configuring VRRP

To configure VRRP you must configure two or more FortiGate interfaces or routers with the same virtual router ID and IP address. Then these FortiGates or routers can automatically join the same VRRP domain. You must also assign priorities to each of the FortiGate interfaces or routers in the VRRP domain. One of the FortiGate interfaces or routers must have the highest priority to become the primary (or master) router. The other FortiGates or routers in the domain are assigned lower priorities and become backups. All of the routers in the VRRP domain should have different priorities. If the primary router fails, VRRP automatically fails over to the router in the domain with the next highest priority.

You configure VRRP from the FortiGate CLI by adding a VRRP virtual router to a FortiGate interface. You can add VRRP virtual routers to multiple FortiGate interfaces and you can add more than one virtual router to the same interface.

Adding a VRRP virtual router to a FortiGate interface

Use the following command to add an IPv4 VRRP virtual router to the port10 interface of a FortiGate. This VRRP virtual router has a virtual router ID of 200, uses IP address 10.31.101.200 and has a priority of 255. Since this is the highest priority, this interface is configured to be the primary router of the VRRP domain with ID number 200.

VRRP can be configured only on physical interfaces or VLAN interfaces. You cannot configure VRRP on hardware-switch interfaces where multiple physical interfaces are combined into a hardware switch interface.

```
config system interface
edit port10
config vrrp
edit 200
set vrip 10.31.101.200
set priority 255
end
end
```

Setting up VRRP failover

VRRP routers in a VRRP domain periodically send VRRP advertisement messages to all of the routers in the domain to maintain one router as the primary router and the others as backup routers. The primary router is the one with the highest priority. If the backup routers stop receiving these packets from the primary router, the backup router with the highest priority becomes the new primary router.

The primary router stops sending VRRP advertisement messages if it either fails or becomes disconnected. You can also configure VRRP destination addresses that the primary router monitors. If the primary router becomes unable to connect to these destination addresses, it stops sending VRRP advertisement messages and the backup router with the highest priority becomes the primary router. You can add one or two destination addresses to a VRRP configuration. To be most effective, these destination addresses should be remote addresses.

For example, configure IPv4 VRRP on port14 with two destination address:

```
config system interface
edit port14
config vrrp
edit 12
set vrdst 10.10.10.20 10.20.20.10
end
```

Configure IPv6 VRRP on port23 with one destination address:

```
config system interface
edit port23
config ipv6
config vrrp6
edit 223
set vrdst 2001:db8:1::12
end
```

IPv4 VRRP active failover

You can reduce IPv4 VRRP failover times with the `vrdst-priority` option. This option causes the primary router to actively signal to the backup routers when the primary router can't reach its configured destination address or addresses. The primary router does this by sending a lower priority for itself in the VRRP advertisement messages. You set this lower priority with the `vrdst-priority` option. The backup router with the highest priority becomes the new primary router and takes over processing traffic.

The following example configures the primary router to have a priority of 255 so it should always become the primary router. The command also sets `vrdst-priority` to 10. So if the primary router can no longer connect to its destination address of 10.10.10.1, the primary router informs the VRRP group that its priority is now 10.

```
config system interface
  edit port10
    config vrrp
      edit 12
        set vrip 10.31.101.200
        set priority 255
        set vrdst 10.10.10.1
        set vrdst-priority 10
      end
    end
```

Failover of IPv4 firewall VIPs and IP Pools

FortiOS VRRP supports failover of firewall VIPs and IP Pools when the status of a router changes. This feature introduces a new proxy ARP setting to map VIP and IP Pool address ranges to each router's Virtual MAC (VMAC). After failover, the IP ranges added to the new primary router are routed to the new primary router's VMAC.

Use the following command to add a proxy ARP address range and a single IP address to a router added to a FortiGate's port5 interface. The address range and single IP address should match the address range or single IP for VIPs or IP pools added to the port5 interface:

```
config system interface
  edit port5
    config vrrp
      edit 1
        config proxy-arp
          edit 1
            set ip 192.168.62.100-192.168.62.200
          next
          edit 2
            set ip 192.168.62.225
          end
        end
      end
    end
```

Changing the advertisement message interval

By default, VRRP advertisement messages are sent once a second. You can use the following command to change the frequency of sending these messages. The range is 1 to 255 seconds.

For example, configure an IPv4 VRRP to send advertisement messages every 10 seconds:

```
config system interface
  edit port14
    config vrrp
      edit 12
        set adv-interval 10
      end
    end
```

Configure IPv6 VRRP to send advertisement messages every 20 seconds:

```
config system interface
  edit port23
    config ipv6
      config vrrp6
        edit 223
          set adv-interval 20
        end
      end
    end
```

Changing how long backup routers wait before assuming the primary router has failed

The VRRP startup time is the maximum time that a backup router waits between receiving advertisement messages from the primary router. If the backup router has to wait longer than the start-time, it assumes the primary router has failed and becomes the new primary router.

The default startup time is 3 seconds and the range is 1 to 255 seconds.

In some cases the advertisement messages may be delayed. For example, some switches with spanning tree enabled may delay some of the advertisement message packets. If you find that backup routers are attempting to become primary routers even though the primary router hasn't failed, you can extend the start time to make sure the backup routers wait long enough for the advertisement messages.

For example, set the IPv4 VRRP startup time to 10 seconds:

```
config system interface
  edit port14
    config vrrp
      edit 12
        set start-time 10
      end
    end
```

Configure set the IPv6 VRRP startup time to 15 seconds:

```
config system interface
  edit port23
    config ipv6
      config vrrp6
        edit 223
          set start-time 15
        end
      end
    end
```

Setting up VRRP groups

If you have added VRRP routers to multiple interfaces of the same FortiGate, each of those routers will be in a different VRRP domain. If one of these routers switches to backup (for example, if it can't connect to its destination), you might want all of the routers on this FortiGate to also switch to backup. In other words, if one of the VRRP routers added to a FortiGate fails, you might want all of the VRRP routers added to the FortiGate to also fail.

However, VRRP can only check the status of the routers in a single VRRP domain and can't track the status of routers in other domains. So, if you have multiple VRRP domains on a single FortiGate, one of them can switch to backup but the others can remain operating normally.

VRRP groups allow you to avoid this problem. You can add all of the VRRP virtual routers on the same FortiGate to a VRRP group. If one of the virtual routers in a VRRP group switches to backup, the VRRP group forces all of

the other virtual routers in the same group to also switch to backup. So all VRRP traffic being processed by the FortiGate fails over to other devices in your network.

The status of the virtual routers in a VRRP group can only change when one or more of the virtual routers in the group changes status. You cannot use a VRRP group to manually change the status of the virtual routers in the group.

Use the following command to add two VRRP routers to a VRRP group with a group ID of 10. The VRRP group ID can be between 1 and 65535.

```
config system interface
  edit port10
    config vrrp
      edit 200
        set vrip 10.31.101.200
        set priority 255
        set vrpgrp 10
      end
    end
  edit port20
    config vrrp
      edit 100
        set vrip 10.23.1.223
        set priority 20
        set vrpgrp 10
      end
    end
  end
```

Using VRRP virtual MAC addresses

The VRRP virtual MAC address (or virtual router MAC address) is a shared MAC address adopted by the primary router. If the primary router fails, the same virtual MAC address is picked up by the new primary router allowing all devices on the network to transparently connect to the default route using the same virtual MAC address. You must enable the VRRP virtual MAC address feature on all members of a VRRP domain.

Each VRRP router is associated with its own virtual MAC address. The last part of the virtual MAC depends on the VRRP virtual router ID using the following format:

```
00-00-5E-00-01-<VRID_hex>
```

Where <VRID_hex> is the VRRP virtual router ID in hexadecimal format in Internet standard bit-order. For more information about the format of the virtual MAC see [RFC 3768](#).

Some examples:

- If the VRRP virtual router ID is 10 the virtual MAC would be 00-00-5E-00-01-0a.
- If the VRRP virtual router ID is 200 the virtual MAC would be 00-00-5E-00-01-c8.

The VRRP virtual MAC address feature is disabled by default. When you enable the feature on a FortiGate interface, all of the VRRP routers added to that interface use their own VRRP virtual MAC address. Each virtual MAC address will be different because each virtual router has its own ID.

Use the following command to enable the VRRP virtual MAC address for an IPv4 VRRP configuration on the port2 interface:

```
config system interface
```

```
edit port2
    set vrrp-virtual-mac enable
end
end
```

The port2 interface will now accept packets sent to the MAC addresses of the IPv4 VRRP virtual routers added to this interface.

Since devices on the LAN do not have to learn a new MAC address for a new VRRP router in the event of a failover, this feature can improve network efficiency, especially on large and complex networks.

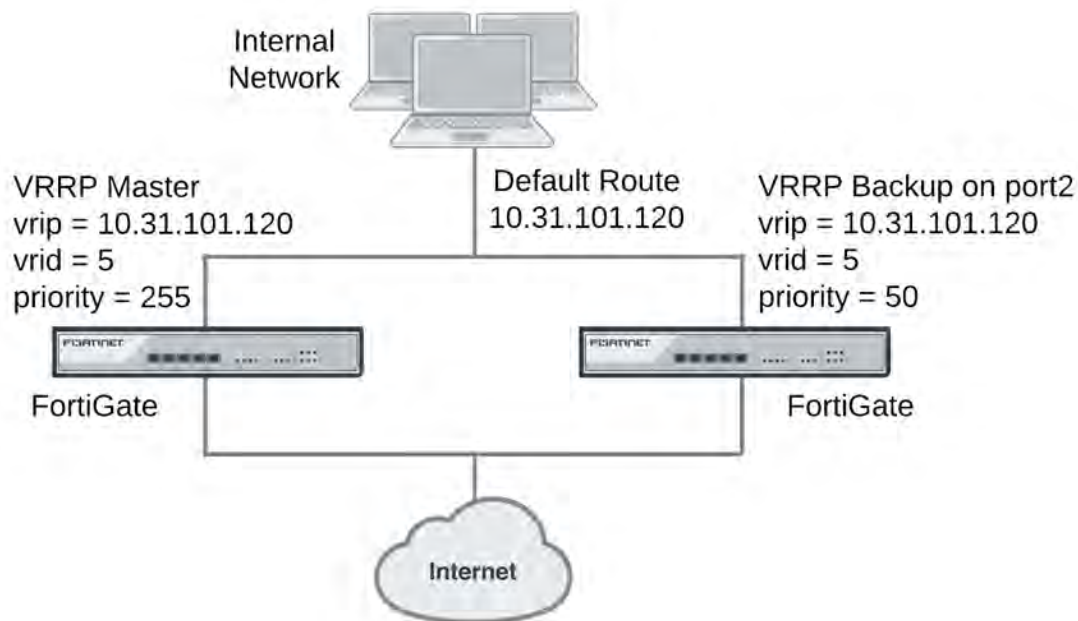

If the VRRP virtual MAC address feature is disabled, the VRRP domain uses the MAC address of the master. In the case of a FortiGate VRRP virtual router this is the MAC address of the FortiGate interface that the VRRP virtual routers are added to. If a master fails, when the new master takes over it sends gratuitous ARPs to associate the VRRP virtual router IP address with the MAC address of the new master (or the interface of the FortiGate that has become the new master). If the VRRP virtual MAC address is enabled the new master uses the same MAC address as the old master.

Example VRRP configuration: two FortiGates in a VRRP domain

This example includes a VRRP domain consisting of two FortiGates that connect an internal network to the Internet. As shown below, the internal network's default route is 10.31.101.120.

The FortiGate port2 interfaces connect to the internal network. A VRRP virtual router is added to each FortiGate's port2 interface. The virtual router IP address is 10.31.101.120 (the internal network's default route) and the virtual router's ID is 5. The VRRP priority of the primary router is set to 255 and the VRRP priority of the backup router is 50. The port2 interface of each FortiGate should have an IP address that is different from the virtual router IP address and the port2 interface IP addresses should be different from each other.

This example also includes enabling the VRRP virtual MAC address on both FortiGate port2 interfaces so that the VRRP domain uses the VRRP virtual MAC address.

Example VRRP configuration with two FortiGates**To configure the FortiGates for VRRP**

1. Select one of the FortiGates to be the primary VRRP router and the other to be the backup router.
2. From the primary router CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 255
      end
    end
  end
```

3. From the backup router CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 50
      end
    end
  end
```

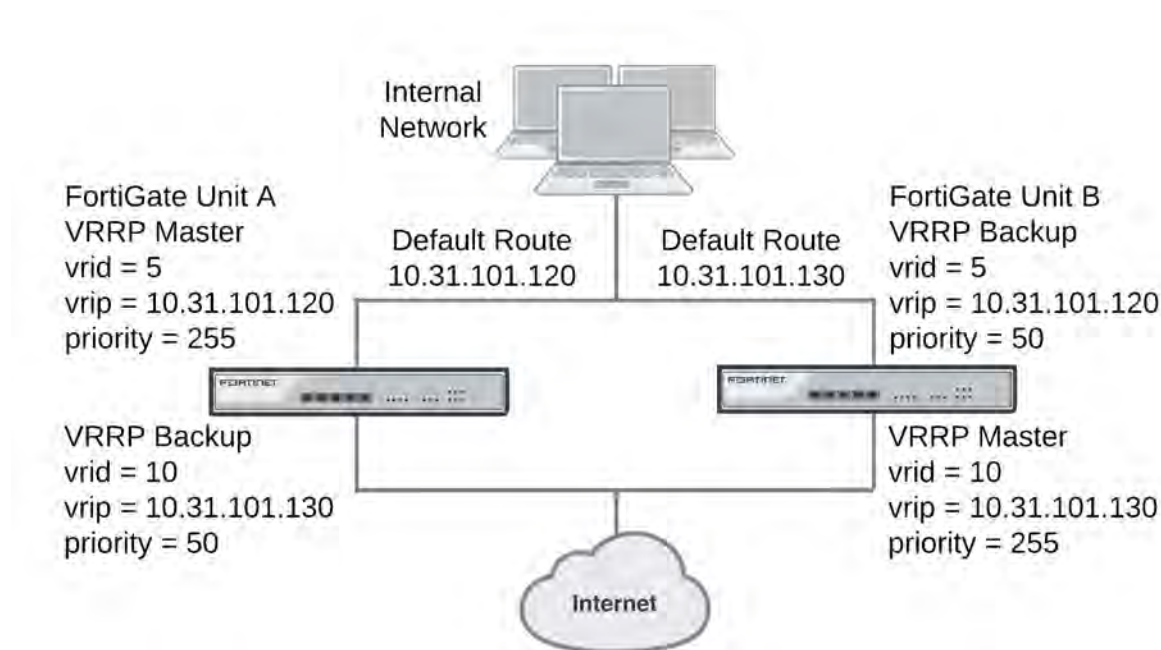

Example VRRP configuration: VRRP load balancing two FortiGates and two VRRP groups

In this configuration two VRRP groups are involved. Each FortiGate participates in both of them. One FortiGate is the primary router of one group and the other FortiGate is the primary router of the other group. The network distributes traffic between two different default routes (10.31.101.120 and 10.31.101.130). One VRRP group is configured with one of the default route IP addresses and the other VRRP group gets the other default route IP address. During normal operation, both FortiGates are processing traffic and the VRRP groups are used to load balance the traffic between the two FortiGates.

If one of the FortiGates fails, the remaining FortiGate becomes the primary router of both VRRP groups. The network sends all traffic for both default routes to this FortiGate. The result is a configuration that, under normal operation load, balances traffic between two FortiGates, but if one of the FortiGates fails, all traffic fails over to the FortiGate that is still operating.

This example also includes enabling the VRRP virtual MAC address on both FortiGate port2 interfaces so that the VRRP groups use their VRRP virtual MAC addresses.

Example VRRP configuration with two FortiGates and two VRRP groups

To configure the FortiGates

1. Log into the CLI of FortiGate A.
2. Enter the following to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate A:

```
config system interface
edit port2
set vrrp-virtual-mac enable
config vrrp
edit 50 (32)
set vrip 10.31.101.120
```

```
        set priority 255
    next
    edit 100 (64)
        set vrip 10.31.101.130
        set priority 50
    end
end
```

3. Log into the CLI of FortiGate B.

4. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate B:

```
config system interface
    edit port2
        set vrrp-virtual-mac enable
    config vrrp
        edit 50
            set vrip 10.31.101.120
            set priority 50
        next
        edit 100
            set vrip 10.31.101.130
            set priority 255
        end
    end
end
```

Optional VRRP configuration settings

In addition to the basic configuration settings, you can change to the VRRP configuration in the following ways. All of these options apply to both IPv4 and IPv6 VRRP unless noted.

- Enable or disable individual virtual router configurations using the `status` option. Normally virtual router configurations are enabled but you can temporarily disable one if it is not required.
- Enable or disable preempt mode using the `preempt` option. In preempt mode, a higher priority backup router can preempt a lower priority primary router. This can happen if the primary router has failed, a backup router has become the primary router, and the failed primary router restarts. Since the restarted router has a higher priority, if preempt mode is enabled the restarted router replaces the current primary router becoming the new primary router. Preempt mode is enabled by default.
- You can add one or two destination addresses (`vrdst`) to a VRRP configuration. To be most effective, these destination addresses should be remote addresses.

FortiGate-6000 and FortiController-5000 support for VRRP HA

FortiGate-6000 devices and FortiController-5000 Session Aware Load Balancing Clustering (SLBC) both support the Virtual Router Redundancy Protocol (VRRP). You can add FortiGate-6000 devices and FortiController-5000 SLBC configurations to VRRP clusters. These VRRP clusters can include redundant similar hardware platforms or a variety of routers as long as they all support VRRP.

Configure VRRP on a FortiGate-6000 devices or a FortiController-5000 by creating a VRRP domain and adding one or more FortiGate-6000 or FortiController front panel interfaces to the domain.

Just like any VRRP domain, during normal operation, the primary router sends outgoing VRRP routing advertisements. Both the primary and backup routers listen for incoming VRRP advertisements from other routers

in the VRRP domain. If the primary router fails, the new primary router takes over the role of both sending and receiving VRRP advertisements.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two or more FortiGates can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGates and the FGSP performs session synchronization of IPv4 and IPv6 TCP, SCTP, UDP, ICMP, expectation, and NAT sessions and IPsec tunnels to keep the session tables of the FortiGates synchronized. If one of the FortiGates fails, session failover occurs and active sessions fail over to the FortiGates that are still operating. This failover occurs without any loss of data. As well, the external routers or load balancers will detect the failover and re-distribute all sessions to the peers that are still operating.

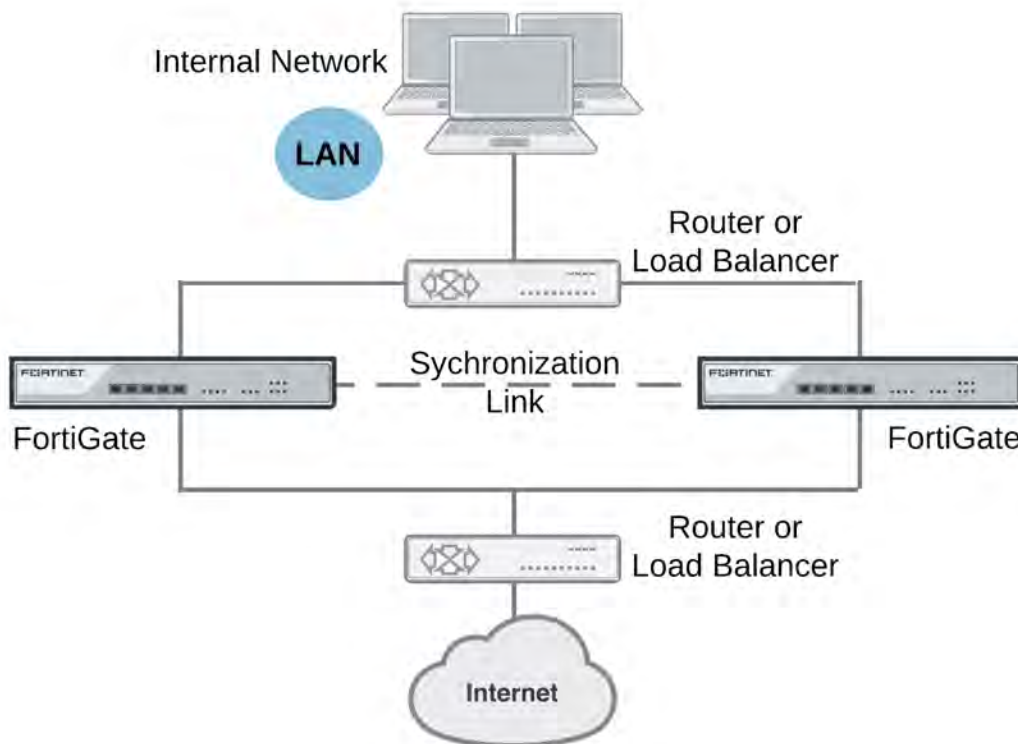

The FortiGates operate as peers that process traffic and synchronize sessions with other FortiGates in the cluster. An FGSP cluster can include from 2 to 16 FortiGates. Adding more FortiGates increases the CPU and memory required to keep all of the FortiGates synchronized. So depending on your network conditions, adding too many FortiGates to an FGSP cluster may reduce overall performance.

The FortiGates in the FGSP cluster must be the same model and be running the same firmware version. You use the `config system cluster-sync` command to configure FGSP between the FortiGates and the `config system ha` command to configure what is synchronized.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. The FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions and IPsec tunnels.

The FGSP can be used instead of FGCP HA to provide **session synchronization** between two peer FortiGates. If the external load balancers direct all sessions to one peer the affect is similar to active-passive FGCP HA. If external load balancers or routers load balance traffic to both peers, the effect is similar to active-active FGCP HA. The load balancers should be configured so that all of the packets for any given session are processed by the same peer. This includes return packets.

FGSP HA

By default, FGSP synchronizes all IPv4 and IPv6 TCP sessions, IPsec tunnels, and also synchronizes the configuration of the FortiGates.

You can optionally enable session pickup to synchronize connectionless (UDP and ICMP) sessions, expectation sessions, and NAT sessions. If you do not enable session pickup, the FGSP does not share session tables for the particular session type and sessions do not resume after a failover. All sessions are interrupted by the failover and must be re-established at the application level. Many protocols can successfully restart sessions with little, or no, loss of data. Others may not recover easily. Enable session pickup for sessions that may be difficult to reestablish. Since session pickup requires FortiGate memory and CPU resources, only enable this feature for sessions that you need to have synchronized.

The synchronization link is set up in the same way as FGCP heartbeat interfaces. You must connect the synchronization link interfaces together and use the heartbeat device (hbdev) option to add the heartbeat devices to the configuration.

You can also optionally add filters to control which sessions are synchronized. You can add filters to only synchronize packets from specified source and destination addresses, specified source and destination interfaces, and specified services.

Load balancing and session failover is done by external routers or load balancers instead of by the FGSP. The FortiGates only perform session synchronization to support session failover as well as configuration synchronization.

Configuring FGSP HA cluster-sync instances

You use the following command to configure an FGSP HA cluster-sync instance.

```
config system cluster-sync
  edit 1
    set peerip <peer-ip-address>
    set peervd <vdom-name>
    set syncvd <vdom-name>
  end
```

Where:

- `peerip` is the IP address of an interface of another FortiGate in the FGSP cluster that this configuration synchronizes sessions to.
- `peervd` the name of the virtual domain that contains the session synchronization link interface on the peer unit. Usually both peers would have the same `peervd`. Multiple session synchronization configurations can use the same `peervd`. The default VDOM name is `root`.
- `syncvd` is the name of one or more VDOMs that should be synchronized by this cluster-sync instance. If multiple VDOMs are not enabled, `syncvd` should be set to `root`, which is the default setting.

For FGSP HA to work properly, all VDOMs to be synchronized must be added to all of the FortiGates in cluster. The names of the matching interfaces in each VDOM must also be the same; this includes the names of matching VLAN interfaces. Note that the index numbers of the matching interfaces and VLAN interfaces can be different. Also the VLAN IDs of the matching VLAN interfaces can be different. If you enable configuration synchronization this will happen automatically.

This command creates a cluster-sync instance that causes a FortiGate to synchronize the TCP sessions of one of its VDOMs (by default the root VDOM) to the root VDOM of another FortiGate (which would become another FortiGate in the FGSP cluster). You can also use the `config system ha` command to synchronize more session types and to synchronize the configuration. Cluster-sync instances are not synchronized and must be added to each FortiGate in the cluster.

A cluster of two FortiGates would only require one `cluster-sync` instance for each VDOM to be synchronized. This instance would synchronize the sessions from the root VDOM of one FortiGate to the root VDOM of the other. The second FortiGate would also include a cluster-sync instance to synchronize its root VDOM with the other FortiGate's root VDOM.

In a multiple VDOM configuration, you add a separate cluster-sync instance for each VDOM to be synchronized. You don't have to synchronize all VDOMs. If multiple VDOMs are enabled, the `config system cluster-sync` command is a global command.

FGSP clusters with three or more FortiGates

If an FGSP cluster includes three or more FortiGates you must explicitly define all of the cluster-sync instances that you need. In a cluster of four FortiGates, each FortiGate can be synchronized with up to three other FortiGates. So, to synchronize all of the FortiGates, you must add three cluster-sync instances to each FortiGate (or $n-1$, where n is the number of FortiGates in the cluster).

Selecting the sessions to synchronize

You can add a cluster-sync instance with a filter to only synchronize some sessions. A filter can be added to a cluster-sync instance as follows:

```
config system cluster-sync
  edit 1
    set peerip <peer-ip-address>
    set peervd <vdom-name>
    set syncvd <vdom-name>
    config session-sync-filter
      srcintf <interface-name>
      dstintf <interface-name>
      srcaddr x.x.x.x x.x.x.x
      dstaddr x.x.x.x x.x.x.x
      srcaddr6 ::/x
      dstaddr6 ::/x
    end
  end
end
```

You can use the filter to only synchronize sessions according to the session source and destination interface and IPv4 to IPv6 address.

You can only add one filter to a cluster-sync instance. To create multiple filters you must create multiple cluster-sync instances.

Synchronizing TCP and SCTP sessions

Use the following to enable session synchronization for TCP and SCTP sessions and to configure the FGSP to use the port8 interface for synchronizing traffic:

```
config system ha
  set session-pickup enable
  set hbdev "port8" 50
end
```

Automatic session sync after peer reboot

You can configure your FGSP cluster to resume sessions more smoothly after a failed FortiGate rejoins the cluster. In some cases when a failed FortiGate in the cluster comes back up it may begin processing sessions before the session table from the other FortiGate in the cluster has been synchronized to it. When this happens, the FortiGate may drop packets until the session synchronization is complete.

Shutting down interfaces during session synchronization

This feature allows you to shut down some interfaces on the failed FortiGate when it is starting up so that it will not accept packets until session synchronization is complete. Then the interfaces are brought up and traffic can flow. While the interfaces are down, the FortiGate that had not failed keeps processing traffic.

Use the following to select the interfaces to shutdown while waiting for session synchronization to complete:

```
config system cluster-sync
  edit 1
    set down-intfs-before-sess-sync port1 port2
  end
```

Heartbeat monitoring

If the FortiGate that was running fails before session synchronization is complete, the FortiGate that is restarting will not be able to complete session synchronization and will not turn on its shutdown interfaces. To prevent this from happening, FGSP includes heartbeat monitoring. Using heartbeat monitoring, the FortiGate that is waiting for session synchronization to finish can detect that the other FortiGate is down and turn on its interfaces even if session synchronization is not complete. You can use the following to change the heartbeat interval (`hb-interval`) and lost heartbeat threshold (`hb-lost-threshold`) to change heartbeat monitoring timing.

```
config system cluster-sync
  edit 1
    set hb-interval 2
    set hb-lost-threshold 3
  end
```

Synchronizing the configuration

The FGSP includes configuration synchronization, allowing you to make configuration changes once for all of the FortiGates in the cluster, instead of requiring you to make redundant configuration changes on each FortiGate.

By default, configuration synchronization is disabled. You can enter the following to enable it:

```
config system ha
  set standalone-config-sync enable
end
```

You must enter this command on all of the FortiGates in the FGSP cluster. When you enable synchronizing the configuration, the FGSP uses FGCP primary unit selection to select a config sync primary (or master) FortiGate. The other FortiGates in the FGSP cluster become config sync backup FortiGates. The FGSP synchronizes all configuration changes that you make on the config sync primary FortiGate to the config sync backup FortiGates. Fortinet recommends making all configuration changes on the config sync primary FortiGate.

Config sync primary FortiGate selection

The FGSP cluster uses FGCP primary unit selection to select the FGSP config sync primary FortiGate (see [Primary unit selection on page 1744](#)). So normally, the FortiGate with the highest serial number would become the primary FortiGate.

You can use device priority select one of the FortiGates to become the config sync primary FortiGate. For example, the following command enables configuration synchronization on a FortiGate and sets a higher device priority than the default of 128 to make sure that this FortiGate becomes the primary FortiGate.

```
config system ha
  set standalone-config-sync enable
  set priority 250
end
```

Settings that are not synchronized

FGSP configuration synchronization does not synchronize settings that identify the FortiGate to the network. The following settings are not synchronized:

- Transparent mode management IPv4 and IPv6 IP addresses and default gateways.
- All `config system cluster-sync` settings.
- All `config system interface` settings except `vdom`, `vlanid`, `type` and `interface`.
- All `config firewall sniffer` settings.

- All router BFD and BFD6 settings.
- The following BGP settings: `as`, `router-id`, `aggregate-address`, `aggregate-address6`, `neighbor-group`, `neighbor`, `network`, and `network6`.
- The following OSPF settings: `router-id`, `area`, `ospf-interface`, `network`, `neighbor`, and `summary-address`.
- The following OSPF6 settings: `router-id`, `area`, and `ospf6-interface`.
- All RIP settings.
- All policy routing settings.
- All static routing settings.

Backing up and restoring the configuration of FGSP cluster members

You should maintain separate backup configuration files for each FortiGate in the FGSP cluster. Separate configuration files are required because not all settings are synchronized.

Restoring the configuration of one cluster member from a configuration file does not affect the configurations of other FortiGates in the cluster. You should restore each cluster member separately with its own configuration file.

FGSP and firmware upgrades

The steps to follow to upgrade the firmware running on an FGSP cluster depend on whether you have enabled configuration synchronization ([Synchronizing the configuration on page 1995](#)) or not:

- If you have not enabled configuration synchronization, you must upgrade the firmware separately on each FortiGate in the cluster. Upgrading the firmware of each FortiGate interrupts traffic through that FortiGate.
- If you have enabled configuration synchronization, you can upgrade the cluster firmware by upgrading the firmware running on the sync primary FortiGate. The FGSP then sends the new firmware image to the config sync backup FortiGates and all of the FortiGates in cluster install the new firmware and restart. The firmware upgrade simultaneously interrupts traffic through all of the FortiGates in the cluster.

FGSP firmware upgrade best practice

Fortinet recommends using the following steps to upgrade the firmware of the FortiGates in an FGSP cluster. Follow these steps whether or not you have enabled configuration synchronization.

For an example FGSP cluster of two FortiGates (FGT-1 and FGT-2):

1. Switch all traffic to FGT-1.
Configure the load balancer or router that distributes traffic between the FortiGates to send all traffic to one of the FortiGates in the FGSP cluster (in this case FGT-1).
2. Disconnect FGT-2 from your network.
Make sure to also disconnect the interfaces that allow heartbeat and synchronization communication with FGT-1. You want to prevent FGT-2 from communicating with FGT-1.
3. Upgrade the firmware of FGT-2.
4. Re-connect FGT-2's traffic interfaces (but not the interfaces used for heartbeat and synchronization communication with FGT-1).
5. Switch all traffic to the newly upgraded FGT-2.
Configure the load balancer or router that distributes traffic between the FortiGates to send all traffic to the FortiGate with upgraded firmware.
6. Upgrade the firmware of FGT-1 (while heartbeat and synchronization communication with FGT-2 remains disconnected).

7. Re-connect the FGT-2 interfaces that allow heartbeat and synchronization communication between FGT-1 and FGT-2.
8. Restore the original traffic distribution between FGT-1 and FGT-2.
Configure the load balancer or router to again distribute traffic to both FortiGates in the FGSP cluster.

Backing up and restoring the configuration of an FGSP cluster

You should maintain separate backup configuration files for each FortiGate in the FGSP cluster. When you restore the configuration of one of the FortiGates in an FGSP cluster, the FGSP does not synchronize the configuration file to the other FortiGates in the FGSP cluster. Instead you must back up each FortiGate separately and restore the configuration of each FortiGate separately with its own configuration file.

IPsec tunnel synchronization

When you use the `config system cluster-sync` command to enable FGSP, IPsec keys and other runtime data (but not actual tunnel sessions) are synchronized between cluster units. This means that if one of the cluster units goes down, the cluster units that are still operating can quickly get IPsec tunnels re-established without re-negotiating them. However, after a failover, all existing tunnel sessions on the failed FortiGate have to be restarted on the FortiGates that are still operating.

IPsec tunnel sync supports both static and dialup IPsec tunnels. For IPsec tunnel synchronization to work, the interfaces on the FortiGates that are tunnel endpoints must have the same IP addresses and external routers must be configured to load balance IPsec tunnel sessions to the FortiGates in the cluster.

Optionally synchronizing IKE routes

You can use the following command to control whether IKE routes are synchronized to all units in the FGSP cluster.

```
config system cluster-sync
  edit 0
    set slave-add-ike-routes {enable | disable}
  end
```

Enable to synchronize IKE routes, disable if you do not need to synchronize IKE routes. Enabling routing synchronization is optional but doing so increases synchronization overhead and bandwidth usage. If you have problems with IPsec VPN tunnel synchronization, you may want to enable synchronizing routes. Otherwise you could leave it disabled to improve performance and save bandwidth.

Synchronizing UDP and ICMP (connectionless) sessions

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if required you can configure the FGSP to synchronize UDP and ICMP sessions by entering the following:

```
config system ha
  set session-pickup enable
  set session-pickup-connectionless enable
end
```

Synchronizing NAT sessions

By default, NAT sessions are not synchronized. However, the FGSP can synchronize NAT sessions if you enter the following:

```
config system ha
    set session-pickup enable
    set session-pickup-nat enable
end
```

However, if you want NAT sessions to resume after a failover, you should not configure NAT to use the destination interface IP address since the FGSP FortiGates have different IP addresses. With this configuration, after a failover all sessions that include the IP addresses of interfaces on the failed FortiGate will have nowhere to go since the IP addresses of the failed FortiGate will no longer be on the network.

Instead, in an FGSP configuration, if you want NAT sessions to failover, you should use IP pools with the type set to overload (which is the default IP pool type). For example:

```
config firewall ippool
    edit FGSP-pool
        set type overload
        set startip 172.20.120.10
        set endip 172.20.120.20
    end
```

Then when you configure NAT firewall policies, turn on NAT and select to use dynamic IP pool and select the IP pool that you added. Configuration synchronization should add the same IP pools and firewall policies to all FortiGates in the cluster. If configuration synchronization is not enabled you must add the same IP pools and policies to all of the FortiGates in the cluster.

Synchronizing asymmetric sessions

By default, asymmetric sessions are not synchronized. Normally, session synchronization cannot be asymmetric because it is stateful. So all of the packets of a given session must be processed on the same FortiGate. This includes return packets.

However, if you have an asymmetric routing configuration, you can enter the following command to synchronize asymmetric sessions by dynamically detecting asymmetric sessions and disabling anti-reply for these sessions.

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions, a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However, two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

This asymmetric function can also work with connectionless UDP and ICMP traffic. If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates.

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

Synchronizing asymmetric traffic can be very useful in situations where multiple Internet connections from different ISPs are spread across multiple FortiGates. Since it is typically not possible to guarantee Internet-bound traffic leaving via an ISP will return using the exact same ISP, the FGSP provides critical firewall functions in this situation.

Asymmetric sessions may not be synchronized in low latency networks if the reply packet is received before the peer has received the session synchronization packet. This limitation usually only occurs in low latency networks.

The FGSP also has applications in virtualized computing environments where virtualized hosts move between data centers. The firewall session synchronization features of FGSP allow for more flexibility than in traditional firewalling functions.

Synchronizing expectation sessions

FortiOS session helpers keep track of the communication of Layer-7 protocols such as FTP and SIP that have control sessions and expectation sessions. Usually the control sessions establish the link between server and client and negotiate the ports and protocols that will be used for data communications. The session helpers then create expectation sessions through the FortiGate for the ports and protocols negotiated by the control session.

The expectation sessions are usually the sessions that actually communicate data. For FTP, the expectation sessions transmit files being uploaded or downloaded. For SIP, the expectation sessions transmit voice and video data. Expectation sessions usually have a timeout value of 30 seconds. If the communication from the server is not initiated within 30 seconds, the expectation session times out and traffic will be denied.

By default the FGSP does not synchronize expectation sessions and if a failover occurs, the sessions will have to be restarted.

If you want to synchronize expectation sessions so that they will continue after a failover, you can enter the following:

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

Security profile flow-based inspection and asymmetric traffic

Security profile inspection (flow- or proxy-based) for a session is not expected to work properly if the traffic in the session is balanced across more than one FortiGate in either direction. Flow-based inspection should be used in FGSP deployments.

For an environment where traffic is symmetric, security profile inspection can be used with the following limitations:

- No session synchronization for the sessions inspected using proxy-based inspection. Sessions will drop and need to be reestablished after data path failover.
- Sessions with flow-based inspection will failover; however, inspection of failed over sessions after the failover may not work.

A single FortiGate must see both the request and reply traffic for security profile inspection to function correctly. For environments where asymmetric traffic is expected, security profile inspection should not be used.

Notes and limitations

FGSP HA has the following limitations:

- The FGSP is a global configuration option. As a result you can only add one service to a filter configuration. You cannot add custom services or service groups even if virtual domains are not enabled.
- You can only add one filter configuration to a given FGSP configuration. However, you can add multiple filters by adding multiple identical FGSP configurations, each one with a different filter configuration.
- Sessions accepted by security policies with security profiles configured are not synchronized.
- FGSP HA is configured from the CLI.
- FGSP HA is available for FortiGates or virtual domains operating in NAT or transparent mode. NAT sessions are not synchronized in either mode (unless NAT synchronization is enabled as described in [Synchronizing NAT sessions on page 1998](#)). In NAT mode, only sessions for route mode security policies are synchronized. In transparent mode, only sessions for normal transparent mode policies are synchronized.
- FGSP HA is supported for traffic on physical interfaces, VLAN interfaces, zones, aggregate interfaces, and NPx (NP4, NP6 etc.) accelerated interfaces. The FGSP has not been tested for inter-vdom links, between HA clusters, and for redundant interfaces.
- The names of the matching interfaces, including VLAN interfaces, aggregate interfaces and so on, must be the same on both peers.
- An FGSP cluster can include from 2 to 16 FortiGates. Adding more FortiGates increases the CPU and memory required to keep all of the FortiGates synchronized.

Configuring session synchronization links

When FGSP HA is operating, the FortiGates share session information over Ethernet links similar to an HA heartbeat link. Usually you would use the same interface on each FortiGate for session synchronization. If possible you should connect the session synchronization interfaces directly without using a switch or other networking equipment. For FortiGate-5000 systems you can use a backplane interface as the session synchronization link.

You can use different interfaces on each FortiGate for session synchronization links. Also, if you have multiple session synchronization configurations, you can have multiple links between the FortiGates. In fact if you are synchronizing a lot of sessions, you may want to configure and connect multiple session synchronization links to distribute session synchronization traffic to these multiple links.

You cannot configure backup session synchronization links. Each configuration only includes one session synchronization link.

The session synchronization link should always be maintained. If session synchronization communication is interrupted and a failure occurs, sessions will not failover and data could be lost.

Session synchronization traffic can use a considerable amount of network bandwidth. If possible, session synchronization link interfaces should only be used for session synchronization traffic and not for data traffic.

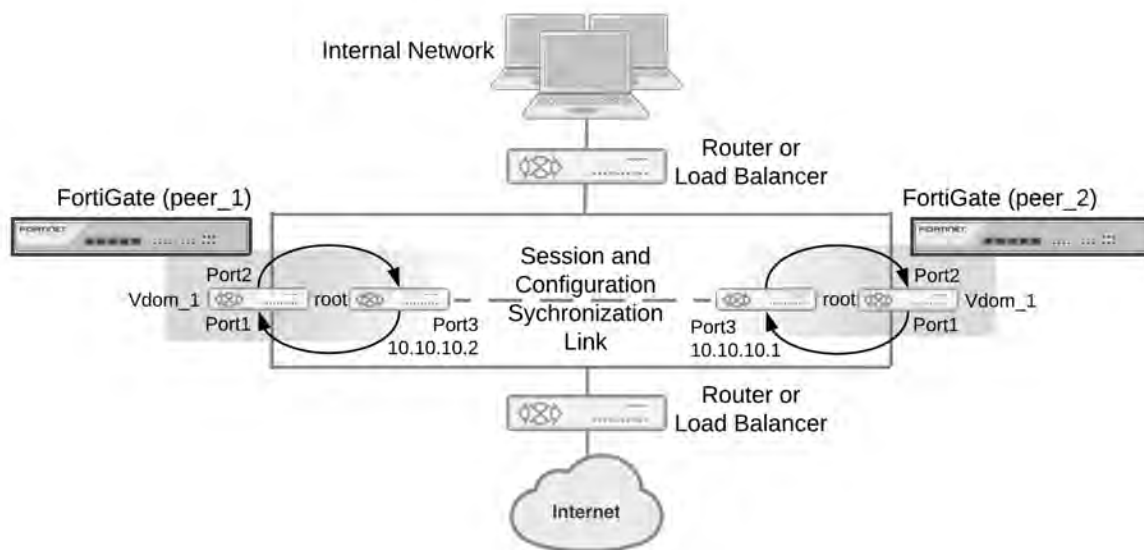

Basic example configuration

The following configuration example shows how to configure basic FGSP HA for the two peer FortiGates shown below.

- The host names of peers are peer_1 and peer_2.
- Both peers are configured with two virtual domains: root and vdom_1.
- All sessions processed by vdom_1 are synchronized.
- The synchronization link interface is port3 which is in the root virtual domain.
- The IP address of port3 on peer_1 is 10.10.10.1.
- The IP address of port3 on peer_2 is 10.10.10.2.

Also on both peers, port1 and port2 are added to vdom_1. On peer_1 the IP address of port1 is set to 192.168.20.1 and the IP address of port2 is set to 172.110.20.1. On peer_2 the IP address of port1 is set to 192.168.20.2 and the IP address of port2 is set to 172.110.20.2.

Example FGSP HA network configuration

To configure FGSP HA

1. Configure the load balancer or router to send all sessions to peer_1.
2. Configure the load balancer or router to send all traffic to peer_2 if peer_1 fails.
3. Use normal FortiGate configuration steps on peer_1:
 - Enable virtual domain configuration.
 - Add the vdom_1 virtual domain.
 - Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
 - Set the IP address of port1 to 192.168.20.1.
 - Set the IP address of port2 to 172.110.20.1.
 - Set the IP address of port3 to 10.10.10.1.
 - Add route mode security policies between port1 and port2 to vdom_1.
4. Enter the following commands to configure session synchronization for peer_1:

```
config system cluster-sync
edit 1
set peerip 10.10.10.2
```

```
set peervd root
set syncvd vdom_1
end
```

5. Use normal FortiGate configuration steps on peer_2:

- Enable virtual domain configuration.
- Add the vdom_1 virtual domain.
- Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
- Set the IP address of port1 to 192.168.20.2.
- Set the IP address of port2 to 172.110.20.2.
- Set the IP address of port3 to 10.10.10.1.
- Add route mode security policies between port1 and port2 to vdom_1.

6. Enter the following command to configure session synchronization for peer_1

```
config system cluster-sync
edit 1
set peerip 10.10.10.1
set peervd root
set syncvd vdom_1
end
```

To synchronize the configuration

Enter the following command on both FortiGates to enable configuration synchronization.

```
config system ha
set standalone-config-sync enable
end
```

The configurations of the FortiGates will now be synchronized. When you make a configuration change on one FortiGate, the change will be synchronized to the other one.

To add filters

You can add a filter to this basic configuration if you only want to synchronize some TCP sessions. For example you can enter the following command to add a filter so that only HTTP sessions are synchronized:

```
config system cluster-sync
edit 1
config filter
set service HTTP
end
end
```

You can also add a filter to control the source and destination addresses of the IPv4 packets that are synchronized. For example, you can enter the following to add a filter so that only sessions with source addresses in the range 10.10.10.100 to 10.10.10.200 are synchronized.

```
config system cluster-sync
edit 1
config filter
set srcaddr 10.10.10.100 10.10.10.200
end
end
```

You can also add a filter to control the source and destination addresses of the IPv6 packets that are synchronized. For example, you can enter the following to add a filter so that only sessions with destination addresses in the range 2001:db8:0:2::/64 are synchronized.

```
config system cluster-sync
  edit 1
    config filter
      set dstaddr6 2001:db8:0:2::/64
    end
  end
end
```

To synchronize TCP sessions

You enter the following to synchronization TCP sessions and set the synchronization link (heartbeat device):

```
config system ha
  set hbdev "port3" 50
  set session-pickup enable
end
```

To synchronize UDP and ICMP sessions

You enter the following to add synchronization of UDP and ICMP sessions to this configuration:

```
config system ha
  set session-pickup enable
  set session-pickup-connectionless enable
end
```

Verifying the FGSP configuration and synchronization

You can use the following diagnose commands to verify that the FGSP and its synchronization functions are operating correctly.

FGSP configuration summary and status

Enter the following command to display a summary of the FGSP configuration and synchronization status:

```
diagnose sys session sync
sync_ctx: sync_started=1, sync_tcp=1, sync_others=1,
sync_expectation=1, sync_redir=0, sync_nat=1, stdalone_sessync=0.
sync: create=12:0, update=0, delete=0:0, query=14
recv: create=14:0, update=0, delete=0:0, query=12
ses pkts: send=0, alloc_fail=0, recv=0, recv_err=0 sz_err=0
nCfgr_sess_sync_num=5, mtu=16000
sync_filter:
1: vd=0, szone=0, dzone=0, saddr=0.0.0.0:0.0.0.0, daddr=0.0.0.0:0.0.0.0,
```

`sync_started=1` shows that synchronization is working. If this is set to 0 then something is not correct with session synchronization and synchronization has not been able to start because of it.

`sync_tcp=1, sync_others=1, sync_expectation=1, and sync_nat=1` show that the FGSP has been configured to synchronize TCP, connectionless, asymmetric, and NAT sessions.

`sync: create=12:0` and `recv: create=14:0` show that this FortiGate has synchronized 12 sessions to its peer and has received 14 sessions from its peer.

`sync_filter` shows the configured FGSP filter. In this case no filter has been created so all sessions are synchronized.

`vd=0` indicates that root VDOM sessions are synchronized.

Verifying that sessions are synchronized

Enter the command `diagnose sys session list` to display information about the sessions being processed by the FortiGate. In the command output look for sessions that should be synchronized and make sure they contain output lines that include `syncd` for example, `state=log may_dirty ndr syncd`) to confirm that they are being synchronized by the FGSP.

```
diagnose sys session list
session info: proto=6 proto_state=05 duration=469 expire=0 timeout=3600

Chapter 16 - IPsec VPN

IPsec VPN

This FortiOS Handbook chapter contains the following sections:

[IPsec VPN concepts](#) explains the basic concepts that you need to understand about virtual private networks (VPNs).

[IPsec VPN overview](#) provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

[IPsec VPN in the web-based manager](#) describes the IPsec VPN menu of the web-based manager interface.

[Gateway-to-gateway configurations](#) explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN. In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks.

[Hub-and-spoke configurations](#) describes how to set up hub-and-spoke IPsec VPNs. In a hub-and-spoke configuration, connections to a number of remote peers and/or clients radiate from a single, central FortiGate hub.

[Dynamic DNS configuration](#) describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a dynamic IP address and a domain name.

[FortiClient dialup-client configurations](#) guides you through configuring a FortiClient dialup-client IPsec VPN. In a FortiClient dialup-client configuration, the FortiGate unit acts as a dialup server and VPN client functionality is provided by the FortiClient Endpoint Security application installed on a remote host.

[FortiGate dialup-client configurations](#) explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit with a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

[Supporting IKE Mode config clients](#) explains how to set up a FortiGate unit as either an IKE Mode Config server or client. IKE Mode Config is an alternative to DHCP over IPsec.

[Internet-browsing configuration](#) explains how to support secure web browsing performed by dialup VPN clients, and hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

[Redundant VPN configurations](#) discusses the options for supporting redundant and partially redundant tunnels in an IPsec VPN configuration. A FortiGate unit can be configured to support redundant tunnels to the same remote peer if the FortiGate unit has more than one interface to the Internet.

[Transparent mode VPNs](#) describes two FortiGate units that create a VPN tunnel between two separate private networks transparently. In transparent mode, all FortiGate unit interfaces except the management interface are invisible at the network layer.

[IPv6 IPsec VPNs](#) describes FortiGate unit VPN capabilities for networks based on IPv6 addressing. This includes IPv4-over-IPv6 and IPv6-over-IPv4 tunnelling configurations. IPv6 IPsec VPNs are available in FortiOS 3.0 MR5 and later.

[L2TP and IPsec \(Microsoft VPN\)](#) explains how to support Microsoft Windows native VPN clients.

[GRE over IPsec \(Cisco VPN\)](#) explains how to interoperate with Cisco VPNs that use Generic Routing Encapsulation (GRE) protocol with IPsec.

[Protecting OSPF with IPsec](#) provides an example of protecting OSPF links with IPsec.

[Redundant OSPF routing over IPsec](#) provides an example of redundant secure communication between two remote networks using an OSPF VPN connection.

[OSPF over dynamic IPsec](#) provides an example of how to create a dynamic IPsec VPN tunnel that allows OSPF.

[BGP over dynamic IPsec](#) provides an example of how to create a dynamic IPsec VPN tunnel that allows BGP.

[Phase 1 parameters](#) provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The basic Phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase VPN connection security further using methods such as extended authentication (XAuth).

[Phase 2 parameters](#) provides detailed step-by-step procedures for configuring an IPsec VPN tunnel. During Phase 2, the specific IPsec security associations needed to implement security services are selected and a tunnel is established.

[Defining VPN security policies](#) explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN tunnel, and how to define a security encryption policy. Security policies control all IP traffic passing between a source address and a destination address.

[Logging and monitoring](#) and [Troubleshooting](#) provide VPN monitoring and troubleshooting procedures.

What's new in FortiOS 5.6

This chapter describes new IPsec VPN features added to FortiOS 5.6.

FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

- Updates to "IPsec VPN Wizard options" on page 2018

FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

IPsec performance improvements for VM (439030)

In IPsec AES-GCM and AES-CBC-SHA mode, this feature leverages Intel AES-NI instructions to accelerate cipher and GCM operations, and uses Intel SSSE3 instructions to accelerate SHA1/SHA256 HMAC operations.

New entries to call Intel aesni directly:

- supported algorithms include: aesni, aesni-gcm, sha1/256/384/512-ssse3/avx/avx2
- some necessary additions, such as aes-gcm generic functions for non-aesni uses

This feature removes the old aes-gcm implementation using Linux Crypto API so that all the software crypto algorithms are under the Crypto_ftnt umbrella.

Two new diagnose commands have been introduced in this feature:

```
diagnose vpn ipsec driver    (shows software crypto drivers in use)
diagnose vpn ipsec cpu      (shows crypto CPU distribution)
```

Improved support for dynamic routing over dynamic IPsec interfaces (435152) (446498) (447569)

Solutions have been introduced to resolve the following issues:

- IPv6 RIP does not successfully exchange routes over ADVPN if the hub has 'set net-device disable'.
- BGP over an IPsec tunnel established by an IKE mode-cfg client connected to IKE mode-cfg server with 'set net-device disable' cannot establish.
- Multicast traffic does not flow over a 'set type dynamic' IPsec interface with 'set net-device disable'.

For 'set type dynamic' + 'set net-device disable' + 'set mode-cfg enable' + 'set add-route disable' then do `_not_` allocate a /30 (/126 for IPv6) as is done when 'set net-device enable', instead allocate a single IP address to the peer.

When the 'set type dynamic' tunnel negotiates, then add an IPsec peer route with the peer's allocated IP address pointing at the newly negotiated tunnel. Note this is an IPsec peer route not a regular route. A regular route is *not* added (unlike the case of 'set net-device enable').

'Config router static' / 'set device xxx' can now refer to a 'set type dynamic' IPsec interface. This allows the admin to define a static route covering the address range of the pool from which peer IP addresses will be allocated.

BMRK IPsec UDP performance for AES256GCM drops after AES-NI checked in (452164)

This new feature fixes the aesni-cbc errors and precomputed the per-SA constant elements for aesni-gcm.

1. aesni-cbc

When ECO 106922 was checked in, there was a known issue that the aesni-cbc driver wasn't working. The solution at that time was aesni plus generic cbc.

With this ECO, we fixed the errors in Intel's aesni-cbc driver so that we can fully leverage the aesni-cbc benefits. The aesni-cbc is faster than aesni plus generic cbc because:

- a. it can do cbc in one go with its 128-bits xmm registers.
- b. it can decrypt 4 blocks at the same time instead of one. It uses alternating AESDEC(Intel's aes instruction) on different blocks to speed up the calculations.

QA's tests show that with this, we can boost aes-cbc-sha1's throughput by 10+%.

2. AES fall-back function changed to Intel's x86_64 assembly from C generic function

When fpu is not available, aesni can't be used and must fall back to a generic function. The assembly aes function should be slightly faster than the C generic one.

This would also slight boost aes throughput for those that don't have aesni but have a x86_64 cpus.

3. aesni-gcm pre-computations

There are some elements in the aesni-gcm algo that maintain constant per-SA. This ECO moves these calculations to the prepare() function so that these calculations are only done once per-SA instead of per-packet.

QA's tests show that this helps to stabilize the 1500D aesni-gcm throughput and make it maintain above 1Gbps (packet size 1360).

4. Added counter reset function for diagnose commands:

```
diagnose vpn ipsec driver clear
diagnose vpn ipsec cpu clear
```

IPsec dial-up interface sharing (379973)

This feature makes it possible to use a single interface for all instances that spawn via a given phase1. Instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

A new CLI option "net-device [enable|disable]" is added in the phase1-interface command sets. The default is "disable" so that the new feature kicks in for all the new configurations. An upgrade feature will add a "set net-device enable" for all the existing configurations so that they will keep the old behavior. Please see the CLI Syntax section below for more details.

Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance as currently happens, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, another new CLI option "tunnel-search" is created. The option is only available when the above "net-device" option is "disable".

There are two options for "tunnel-search", corresponding to the two ways to select the tunnel for outbound traffic. One is "selectors", meaning selecting a peer using the IPSec selectors (proxy-ids). The other is "nexthop" where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc to resolve the routing. The default for "tunnel-search" is "selectors".

Syntax

```
config vpn ipsec phase1-interface
  edit xxx
    set net-device [enable|disable] Enable to create a kernel device for every dialup instance
  next
end
config vpn ipsec phase1-interface
  edit xxx
    set net-device disable
    set tunnel-search [selectors|nexthop] Search for tunnel in selectors or using nexthops
  next
end
```

FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

Support for Brainpool curves specified in RFC 6954 for IKE (412795)

Added support for Brainpool curves specified in [RFC 6954](#) (originally RFC 5639) for IKE. Four new values are added for VPN phase1 and phase2 DH groups.

The allocated transform IDs are 27, 28, 29, 30:

- 27 - Brainpool 224-Bit Curve
- 28 - Brainpool 256-Bit Curve
- 29 - Brainpool 384-Bit Curve
- 30 - Brainpool 512-Bit Curve

Syntax

```
config vpn ipsec phase1/phase1-interface
  edit <name>
    set dhgrp {1 | 2 | 5 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 27 | 28 | 29 | 30}
  next
end
config vpn ipsec phase2/phase2-interface
  edit <name>
    set dhgrp {1 | 2 | 5 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 27 | 28 | 29 | 30}
  next
end
```

Removed "exchange-interface-ip" option from "vpn ipsec phase1" (411981)

The command `exchange-interface-ip` only works for interface-based IPsec VPN (`vpn ipsec phase1-interface`), and so it has been removed from policy-based IPsec VPN (`vpn ipsec phase1`).

IKEv2 ancillary RADIUS group authentication (406497)

This feature provides for the IDi information to be extracted from the IKEv2 AUTH exchange and sent to a RADIUS server, along with a fixed password configurable via CLI, to perform an additional group authentication step prior to tunnel establishment. The RADIUS server may return framed-IP-address, framed-ip-netmask, and dns-server attributes, which are then applied to the tunnel.

It should be noted, unlike Xauth or EAP, this feature does not perform individual user authentication, but rather treats all users on the gateway as a single group, and authenticates that group with RADIUS using a fixed password. This feature also works with RADIUS accounting, including the `phase1 acct-verify` option.

Syntax

```
config vpn ipsec phase1-interface
edit <name>
    set mode-cfg enable
    set type dynamic
    set ike-version 2
    set group-authentication {enable | disable}
    set group-authentication-secret <password>
next
end
```

IPsec mode-cfg can assign IPs from firewall address and sharing IP pools (393331)

This feature adds the ability for users to configure assign-IPs from firewall addresses/groups.

Previously, different policies accessing the same network needed to ensure that non-overlapping IP-ranges were assigned to policies to avoid the same IP address being assigned to multiple clients. With this feature, the address `name` is used to identify an IP pool and different policies can refer to the same IP pool to check for available IPs, thus simplifying the task of avoiding IP conflicts.

Syntax

```
config vpn ipsec phase1-interface
edit <name>
    set mode-cfg enable
    set type dynamic
    set assign-ip-from {range | dhcp | name}
    set ipv4-name <name>
    set ipv6-name <name>
next
end
```

Improve interface-based dynamic IPsec up/down time (379937)

This feature makes it possible to use a single interface for all instances that spawn via a given phase1. Instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

A new CLI option `net-device` is added in the `phase1-interface` command sets. The default is `disable` so that the new feature kicks in for all the new configurations. An upgrade feature will add a `set net-device enable` for all the existing configurations so that they will keep the old behavior.

Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, another new CLI option `tunnel-search` is created. The option is only available when the above `net-device` option is set to `disable`.

There are two options for `tunnel-search`, corresponding to the two ways to select the tunnel for outbound traffic. One is `selectors`, meaning selecting a peer using the IPsec selectors (proxy-ids). The other is

`nexthop` where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc. to resolve the routing. The default for `tunnel-search` is `selectors`.

Syntax

```
config vpn ipsec phase1-interface
  edit <name>
    set net-device {enable | disable}
    set tunnel-search {selectors | nexthop}
  next
end
```

Hide psksecret option when peertype is dialup (415480)

In aggressive mode and IKEv2, when peertype is dialup, pre-shared key is per-user based. There is no need to configure the psksecret in the phase1 setup. Previously, if left unconfigured, CLI would output psksecret error and fail to create the phase1 profile.

To prevent psksecret length check running on the configuration end, the psksecret option will be hidden. Prior to Mantis 397712, the length check passed because it was incorrectly checking the length of encrypted password which is always 204 length long.

Peertype dialup option removed for main mode.

New enforce-ipsec option added to L2TP config (423988)

A new `enforce-ipsec` option is added in L2TP configuration to force the FortiGate L2TP server to accept only IPsec encrypted connections.

Syntax

```
config vpn l2tp
  set eip 50.0.0.100
  set sip 50.0.0.1
  set status enable
  set enforce-ipsec-interface {disable | enable}      (default = disable)
  set usrgroup <group_name>
end
```

IPsec VPN Wizard improvements (368069)

Previously, when using wan-load-balance (WLB) feature, and when configuring an IPsec tunnel with the wizard, the setting 'incoming interface' list does not contain the wan-load-balance nor the wan2 interface. Disabling the WLB permits the configuration.

The solution in 5.6.1 is as follows:

- (368069) The IPsec VPN wizard now allows users to select members of virtual-wan-link (VWL) as IPsec phase1-interface. Before saving, if the phase1 interface is a VWL member, then the Wizard automatically sets the virtual-wan-link as the destination interface in the L2TP policy.
- (246552) List VPN tunnels for VWL members if VWL is set as the destination interface in policy-based IPsec VPN.

IPsec manual key support removed from GUI (436041)

The majority of customers are not using policy-based IPsec today, and beyond that, very few are using manual key VPN. As a result, the IPsec manual key feature is removed from the GUI; the feature store option is removed as well.

Added GUI support for local-gw when configuring custom IPsec tunnels (423786)

Previously, the `local-gw` option was not available on the GUI when configuring a custom IPsec tunnel. This feature adds the `local-gw` setting to the IPsec VPN Edit dialog. The user is able to choose the primary or secondary IP address from the currently selected interface, or specify an ip address manually. Both `local-gw` and `local-gw6` are supported.

Moved the dn-format CLI option from phase1 config to vdom settings (435542)

Previous fix for `dn-format` didn't take into account that, at the time `isakmp_set_peer_identifier` is used, we don't have a connection and haven't matched our gateway yet, so we can't use that to determine the `dn-format` configuration setting.

The solution was to move the `dn-format` CLI option from phase1 config to vdom settings. It is renamed to `ike-dn-format`.

FGT IKE incorrect NAT detection causes ADVPN hub behind VIP to not generate shortcuts (416786)

When ADVPN NAT support was added, only spokes behind NAT was considered. No thought was given to a hub behind a VIP or the problems that occurred due to the way that FortiOS clients behind NAT enable NAT-T even when it is not required.

The solution in 5.6.1 is as follows:

- Moved shortcut determination out of the kernel and up to IKE. The shortcut message now contains the ID of both tunnels so that IKE can check the NAT condition of both.
- Added IKE debug to cover sending the initial shortcut query. The lack of this previously meant it could be awkward to determine if the offer had been converted into a query correctly.
- Added "nat:" output in `diag vpn ike gateway list` output to indicate whether this device or the peer is behind NAT.
- Tweaked the `diag vpn tunnel list` output so that the auto-discovery information now includes symbolic as well as numeric values, which makes it easier to see what type of auto-discovery was enabled.

FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

Improvement to stats crypto command output (403995)

The CLI command `get vpn ipsec stats crypto` now has a better format for the information it shows in differentiating between NP6 lite and SOC3 (CP). To further avoid confusion, all engine's encryption (encrypted/decrypted) and integrity (generated/validated) information is shown under the same heading, not separate headings.

Improved certificate key size control commands (397883)

Proxy will choose the same SSL key size as the HTTPS server. If the key size from the server is 512, the proxy will choose 1024. If the key size is bigger than 1024, the proxy will choose 2048.

As a result, the `firewall ssl-ssh-profile` commands `certname-rsa`, `certname-dsa`, and `certname-ecdsa` have been replaced with more specific key size control commands under `vpn certificate` setting.

CLI syntax

```
config vpn certificate setting
  set certname-rsa1024 <name>
  set certname-rsa2048 <name>
  set certname-dsa1024 <name>
  set certname-dsa2048 <name>
  set certname-ecdsa256 <name>
  set certname-ecdsa384 <name>
end
```

Support bit-based keys in IKE (397712)

As per FIPS-CC required standards, as well as [RFC 4306](#), IKE supports pre-shared secrets to be entered as both ASCII string values and as hexadecimal encoded values. This feature parses hex encoded input (indicated by the leading characters **0x**) and converts the input into binary data for storage.

With this change, the `psksecret` and `psksecret-remote` entries under the IPsec VPN CLI command `config vpn ipsec phase1-interface` have been amended to differentiate user input as either ASCII string or hex encoded values.

IKEv2 asymmetric authentication (393073)

Support added for IKEv2 asymmetric authentication, allowing both sides of an authentication exchange to use different authentication methods, for example the initiator may be using a shared key, while the responder may have a public signature key and certificate.

A new command, `authmethod-remote`, has been added to `config vpn ipsec phase1-interface`.

For more detailed information on authentication of the IKE SA, see [RFC 5996 - Internet Key Exchange Protocol Version 2 \(IKEv2\)](#).

Allow mode-cfg with childless IKEv2 (391567)

An issue that prevented `childless-ike` from being enabled at the same time as `mode-cfg` has been resolved. Both options can now be enabled at once under `config vpn ipsec phase1-interface`.

IKEv2 Digital Signature Authentication support (389001)

FortiOS supports the use of Digital Signature authentication, which changes the format of the Authentication Data payload in order to support different signature methods.

Instead of just containing a raw signature value calculated as defined in the original IKE RFCs, the Auth Data now includes an ASN.1 formatted object that provides details on how the signature was calculated, such as the signature type, hash algorithm, and signature padding method.

For more detailed information on IKEv2 Digital Signature authentication, see [RFC 7427 - Signature Authentication in the Internet Key Exchange Version 2 \(IKEv2\)](#).

Passive static IPsec VPN (387913)

New commands have been added to `config vpn ipsec phase1-interface` to prevent initiating VPN connection. Static IPsec VPNs can be configured in tunnel mode, without initiating tunnel negotiation or rekey.

To allow a finer configuration of the tunnel, the `rekey` option is removed from `config system global` and added to `config vpn ipsec phase1-interface`.

CLI syntax

```
config vpn ipsec phase1-interface
  edit <example>
    set rekey {enable | disable}
    set passive-mode {enable | disable}
    set passive-tunnel-interface {enable | disable}
  end
```

Phase 2 wizard simplified (387725)

Previously, for a site-to-site VPN, phase 2 selectors had their static routes created in the IPsec VPN wizard by adding IP addresses in string format. Now, since addresses and address groups are already created for these addresses, the address group can be used in the route directly. This means that the route can be modified simply by modifying the address/groups that were created when the VPN was initially created.

With this change, the VPN wizard will create less objects internally, and reduce complexity.

In addition, a blackhole route will be created by default with a higher distance-weight set than the default route. This is to prevent traffic from flowing out of another route if the VPN interface goes down. In these instances, the traffic will instead be silently discarded.

Unique IKE ID enforcement (383296)

All IPsec VPN peers now connect with unique IKE identifiers. To implement this, a new `phase1` CLI command has been added (`enforce-unique-id`) which, when enabled, requires all IPsec VPN clients to use a unique identifier when connecting.

CLI syntax

```
config vpn ipsec phase1
  edit <name>
    set enforce-unique-id {keep-new | keep-old | disable} Default is disable.
  next
end
```

Use `keep-new` to replace the old connection if an ID collision is detected on the gateway.

Use `keep-old` to reject the new connection if an ID collision is detected.

FortiView VPN tunnel map feature (382767)

A geospatial map has been added to FortiView to help visualize IPsec and SSL VPN connections to a FortiGate using Google Maps. Adds geographical-IP API service for resolving spatial locations from IP addresses.

This feature can be found under **FortiView > VPN**.

Childless IKEv2 initiation (381650)

As documented in [RFC 6023](#), when both sides support the feature, no child IPsec SA is brought up during the initial AUTH of the IKEv2 negotiation. Support for this mode is not actually negotiated, but the responder indicates support for it by including a CHILDLESS_IKEV2_SUPPORTED Notify in the initial SA_INIT reply. The initiator is then free to send its AUTH without any SA or TS payloads if it also supports this extension.

CLI syntax

```
config vpn ipsec phase1-interface
  edit ike
    set ike-version 2
    set childless-ike enable
  next
end
```

Due to the way configuration payloads (IKEV2_PAYLOAD_CONFIG) are handled in the current code base, mode-cfg and childless-ike aren't allowed to be enabled at the same time. Processing config payloads for mode-cfg requires a child ph2handle to be created, but with childless-ike we completely avoid creating the child ph2 in the first place which makes the two features incompatible. It may be possible to support both in the future, but a deeper rework of the config payload handling is required.

Allow peertype dialup for IKEv2 pre-shared key dynamic phase1 (378714)

Restored `peertype dialup` that was removed in a previous build (when IKEv2 PSK gateway re-validation was not yet supported).

If `peertype` is `dialup`, IKEv2 AUTH verify uses user password in the user group "usrgrp" of phase1. The "psksecret" in phase1 is ignored.

CLI syntax

```
config vpn ipsec phase1-interface
  edit "name"
    set type dynamic
    set interface "wan1"
    set ike-version 2
    set peertype dialup
    set usrgrp "local-group"
  next
end
```

IPsec default phase1/phase1-interface peertype changed from 'any' to 'peer' (376340)

Previously, when `authmethod` was changed to `signature`, `peertype` automatically changed to `peer` and required a peer to be set. This change was done to try to provide a more secure initial configuration, while allowing the admin to set `peertype` back to `any` if that's what they really wanted. The default value was kept at `any` in the CLI. However, this caused problems with copy/pasting configurations and with FMG because if `peertype any` wasn't explicitly provided, the CLI was switched to `peertype peer`.

This patch changes the default `peertype` to `peer` now; `peertype any` is considered non-default and will be printed out on any config listing. Upgrade code has been written to ensure that any older build that was implicitly using `set peertype any` has this setting preserved.

IPsec GUI bug fixes (374326)

Accept type "Any peer ID" is available when creating IPsec tunnel with authmethod, pre-shared key, ikev1 main mode/aggressive mode, and ikev2.

Support for IKEv2 Message Fragmentation (371241)

Added support for IKEv2 Message Fragmentation, as described in [RFC 7383](#).

Previously, when sending and IKE packets with IKEv1, the whole packet is sent once, and it is only fragmented if there is a retransmission. With IKEv2, because [RFC 7383](#) requires each fragment to be individually encrypted and authenticated, we would have to keep a copy of the unencrypted payloads around for each outgoing packet, in case the original single packet was never answered and we wanted to retry with fragments. So with this implementation, if the IKE payloads are greater than a configured threshold, the IKE packets are preemptively fragmented and encrypted.

CLI syntax

```
config vpn ipsec phase1-interface
  edit ike
    set ike-version 2
    set fragmentation [enable|disable]
    set fragmentation-mtu [500-16000]
  next
end
```

IPsec monitoring pages now based on phase 1 proposals not phase 2 (304246)

The IPsec monitor, found under **Monitor > IPsec Monitor**, was in some instances showing random uptimes even if the tunnel was in fact down.

Tunnels are considered as "up" if at least one phase 2 selector is active. To avoid confusion, when a tunnel is down, **IPsec Monitor** will keep the **Phase 2 Selectors** column, but hide it by default and be replaced with **Phase 1** status column.

IPsec VPN concepts

Virtual Private Network (VPN) technology enables remote users to connect to private computer networks to gain access to their resources in a secure way. For example, an employee traveling or working from home can use a VPN to securely access the office network through the Internet.

Instead of remotely logging on to a private network using an unencrypted and unsecure Internet connection, the use of a VPN ensures that unauthorized parties cannot access the office network and cannot intercept any of the information that is exchanged between the employee and the office. It is also common to use a VPN to connect the private networks of two or more offices.

Fortinet offers VPN capabilities in the FortiGate Unified Threat Management (UTM) appliance and in the FortiClient Endpoint Security suite of applications. A FortiGate unit can be installed on a private network, and FortiClient software can be installed on the user's computer. It is also possible to use a FortiGate unit to connect to the private network instead of using FortiClient software.

This chapter discusses VPN terms and concepts including:

VPN tunnels

The data path between a user's computer and a private network through a VPN is referred to as a tunnel. Like a physical tunnel, the data path is accessible only at both ends. In the telecommuting scenario, the tunnel runs between the FortiClient application on the user's PC, or a FortiGate unit or other network device and the FortiGate unit on the office private network.

Encapsulation makes this possible. IPsec packets pass from one end of the tunnel to the other and contain data packets that are exchanged between the local user and the remote private network. Encryption of the data packets ensures that any third-party who intercepts the IPsec packets can not access the data.

Encoded data going through a VPN tunnel

You can create a VPN tunnel between:

- A PC equipped with the FortiClient application and a FortiGate unit
- Two FortiGate units
- Third-party VPN software and a FortiGate unit

For more information on third-party VPN software, refer to the [Fortinet Knowledge Base](#) for more information.

Tunnel templates

Several tunnel templates are available in the IPsec VPN Wizard that cover a variety of different types of IPsec VPN. A list of these templates appear on the first page of the Wizard, located at **VPN > IPsec Wizard**. The tunnel template list follows.

IPsec VPN Wizard options

VPN Type	Remote Device Type		NAT Options	Description
Site to Site	FortiGate		<ul style="list-style-type: none"> No NAT between sites This site is behind NAT The remote site is behind NAT 	Static tunnel between this FortiGate and a remote FortiGate.
	Cisco		<ul style="list-style-type: none"> No NAT between sites This site is behind NAT The remote site is behind NAT 	Static tunnel between this FortiGate and a remote Cisco firewall.
Remote Access	Client-based	FortiClient VPN for OS X, Windows, and Android	N/A	On-demand tunnel for users using the FortiClient software.
		Cisco AnyConnect	N/A	On-demand tunnel for users using the Cisco IPsec client.
	Native	iOS Native	N/A	On-demand tunnel for iPhone/iPad users using the native iOS IPsec client.
		Android Native	N/A	On-demand tunnel for Android users using the native L2TP/IPsec client.
		Windows Native	N/A	On-demand tunnel for Android users using the native L2TP/IPsec client.
Custom	N/A		N/A	No Template.

Cisco's VPN Client has reached its End-of-Life/End-of-Support as of July 30, 2016, and has been replaced by [Cisco AnyConnect Secure Mobility Client](#).

In FortiOS 5.6.4+, the first step of the VPN Creation Wizard (**VPN > IPsec Wizard**) delineates the **Remote Device Type** (for **Remote Access** templates) between **Client-based** and **Native** in order to distinguish FortiClient and Cisco device options from native OS device options.

VPN tunnel list

Once you create an IPsec VPN tunnel, it appears in the VPN tunnel list at **VPN > IPsec Tunnels**. By default, the tunnel list indicates the name of the tunnel, its interface binding, the tunnel template used, and the tunnel status. If you right-click on the table header row, you can include columns for comments, IKE version, mode (aggressive vs main), phase 2 proposals, and reference number. The tunnel list page also includes the option to create a new tunnel, as well as the options to edit or delete a highlighted tunnel.

FortiView VPN tunnel map

A geospatial map can be found under **FortiView > VPN Map** to help visualize IPsec (and SSL) VPN connections to a FortiGate using Google Maps. This feature adds a geographical-IP API service for resolving spatial locations from IP addresses.

VPN gateways

A gateway is a router that connects the local network to other networks. The default gateway setting in your computer's TCP/IP properties specifies the gateway for your local network.

A VPN gateway functions as one end of a VPN tunnel. It receives incoming IPsec packets, decrypts the encapsulated data packets and passes the data packets to the local network. Also, it encrypts data packets destined for the other end of the VPN tunnel, encapsulates them, and sends the IPsec packets to the other VPN gateway. The VPN gateway is a FortiGate unit because the private network behind it is protected, ensuring the security of the unencrypted VPN data. The gateway can also be FortiClient software running on a PC since the unencrypted data is secure on the PC.

The IP address of a VPN gateway is usually the IP address of the network interface that connects to the Internet. Optionally, you can define a secondary IP address for the interface and use that address as the local VPN gateway address. The benefit of doing this is that your existing setup is not affected by the VPN settings.

The following diagram shows a VPN connection between two private networks with FortiGate units acting as the VPN gateways. This configuration is commonly referred to as Gateway-to-Gateway IPsec VPN.

VPN tunnel between two private networks

Although the IPsec traffic may actually pass through many Internet routers, you can visualize the VPN tunnel as a simple secure connection between the two FortiGate units.

Users on the two private networks do not need to be aware of the VPN tunnel. The applications on their computers generate packets with the appropriate source and destination addresses, as they normally do. The FortiGate units manage all the details of encrypting, encapsulating, and sending the packets to the remote VPN gateway.

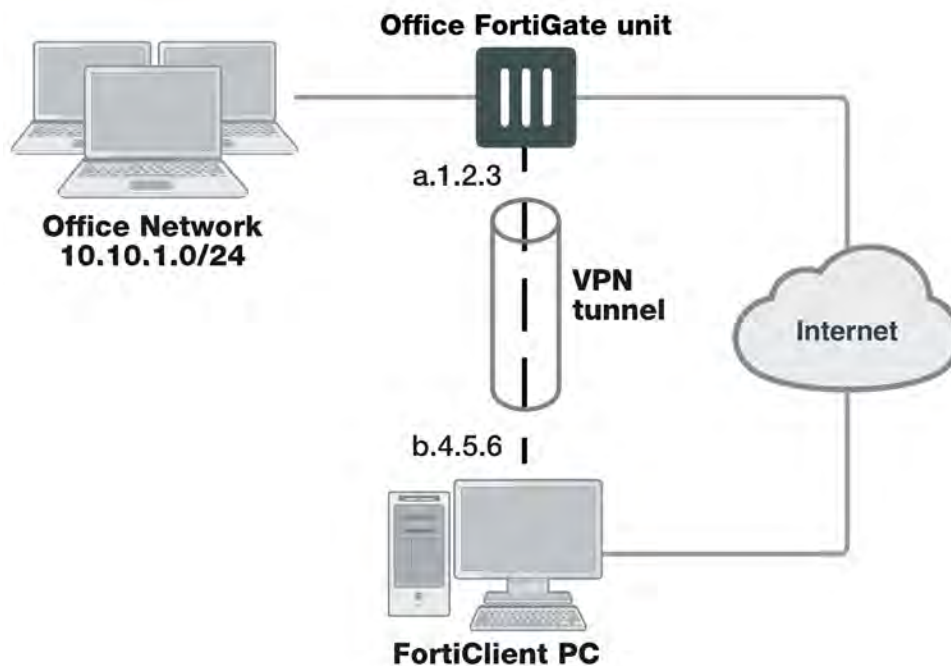

The data is encapsulated in IPsec packets only in the VPN tunnel between the two VPN gateways. Between the user's computer and the gateway, the data is on the secure private network and it is in regular IP packets.

For example User1 on the Site A network, at IP address 10.10.1.7, sends packets with destination IP address 192.168.10.8, the address of User2 on the Site B network. The Site A FortiGate unit is configured to send packets with destinations on the 192.168.10.0 network through the VPN, encrypted and encapsulated. Similarly, the Site B FortiGate unit is configured to send packets with destinations on the 10.10.1.0 network through the VPN tunnel to the Site A VPN gateway.

In the site-to-site, or gateway-to-gateway VPN shown below, the FortiGate units have static (fixed) IP addresses and either unit can initiate communication.

You can also create a VPN tunnel between an individual PC running FortiClient and a FortiGate unit, as shown below. This is commonly referred to as Client-to-Gateway IPsec VPN.

VPN tunnel between a FortiClient PC and a FortiGate unit

On the PC, the FortiClient application acts as the local VPN gateway. Packets destined for the office network are encrypted, encapsulated into IPsec packets, and sent through the VPN tunnel to the FortiGate unit. Packets for other destinations are routed to the Internet as usual. IPsec packets arriving through the tunnel are decrypted to recover the original IP packets.

Clients, servers, and peers

A FortiGate unit in a VPN can have one of the following roles:

- **Server** — responds to a request to establish a VPN tunnel.
- **Client** — contacts a remote VPN gateway and requests a VPN tunnel.
- **Peer** — brings up a VPN tunnel or responds to a request to do so.

The site-to-site VPN shown above is a peer-to-peer relationship. Either FortiGate unit VPN gateway can establish the tunnel and initiate communications. The FortiClient-to-FortiGate VPN shown below is a client-server relationship. The FortiGate unit establishes a tunnel when the FortiClient PC requests one.

A FortiGate unit cannot be a VPN server if it has a dynamically-assigned IP address. VPN clients need to be configured with a static IP address for the server. A FortiGate unit acts as a server only when the remote VPN gateway has a dynamic IP address or is a client-only device or application, such as FortiClient.

As a VPN server, a FortiGate unit can also offer automatic configuration for FortiClient PCs. The user needs to know only the IP address of the FortiGate VPN server and a valid user name/password. FortiClient downloads the VPN configuration settings from the FortiGate VPN server. For information about configuring a FortiGate unit as a VPN server, see the [FortiClient Administration Guide](#).

Encryption

Encryption mathematically transforms data to appear as meaningless random numbers. The original data is called plaintext and the encrypted data is called ciphertext. The opposite process, called decryption, performs the inverse operation to recover the original plaintext from the ciphertext.

The process by which the plaintext is transformed to ciphertext and back again is called an algorithm. All algorithms use a small piece of information, a key, in the arithmetic process of converted plaintext to ciphertext, or vice-versa. IPsec uses symmetrical algorithms, in which the same key is used to both encrypt and decrypt the data. The security of an encryption algorithm is determined by the length of the key that it uses. FortiGate IPsec VPNs offer the following encryption algorithms, in descending order of security:

Encryption	Description
AES-GCM	Galois/Counter Mode (GCM), a block cipher mode of operation providing both confidentiality and data origin authentication.
AES256	A 128-bit block algorithm that uses a 256-bit key.
AES192	A 128-bit block algorithm that uses a 192-bit key.
AES128	A 128-bit block algorithm that uses a 128-bit key.
3DES	Triple-DES, in which plain text is DES-encrypted three times by three keys.
DES	Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key

The default encryption algorithms provided on FortiGate units make recovery of encrypted data almost impossible without the proper encryption keys.

There is a human factor in the security of encryption. The key must be kept secret, known only to the sender and receiver of the messages. Also, the key must not be something that unauthorized parties might easily guess, such as the sender's name, birthday or simple sequence such as 123456.

Diffie-Hellman groups

FortiOS IPsec VPN supports the following Diffie-Hellman (DH) asymmetric key algorithms for public key cryptography.

DH Group	Description
1	More Modular Exponential (MODP) DH Group with a 768-bit modulus.
2	MODP with a 1024-bit modulus.
5	MODP with a 1536-bit modulus.
14	MODP with a 2048-bit modulus.
15	MODP with a 3027-bit modulus.

DH Group	Description
16	MODP with a 4096-bit modulus.
17	MODP with a 6144-bit modulus.
18	MODP with a 8192-bit modulus.
19	256-bit random elliptic curve group.
20	384-bit random elliptic curve group.
21	521-bit random elliptic curve group.
27	Brainpool 224-bit elliptic curve group.
28	Brainpool 256-bit elliptic curve group.
29	Brainpool 384-bit elliptic curve group.
30	Brainpool 512-bit elliptic curve group.

* When using aggressive mode, DH groups cannot be negotiated.

By default, DH group 14 is selected, to provide sufficient protection for stronger cipher suites that include AES and SHA2. If you select multiple DH groups, the order they appear in the configuration is the order in which they are negotiated.

If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client.

When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit.

If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.

IPsec overheads

The FortiGate sets an IPsec tunnel Maximum Transmission Unit (MTU) of 1436 for 3DES/SHA1 and an MTU of 1412 for AES128/SHA1, as seen with `diag vpn tunnel list`. This indicates that the FortiGate allocates 64 bytes of overhead for 3DES/SHA1 and 88 bytes for AES128/SHA1, which is the difference if you subtract this MTU from a typical ethernet MTU of 1500 bytes.

During the encryption process, AES/DES operates using a specific size of data which is block size. If data is smaller than that, it will be padded for the operation. MD5/SHA-1 HMAC also operates using a specific block size.

The following table describes the potential maximum overhead for each IPsec encryption:

IPsec Transform Set	IPsec Overhead (Max. bytes)
ESP-AES (256, 192, or 128), ESP-SHA-HMAC, or MD5	88
ESP-AES (256, 192, or 128)	61
ESP-3DES, ESP-DES	45
ESP-(DES or 3DES), ESP-SHA-HMAC, or MD5	64
ESP-Null, ESP-SHA-HMAC, or MD5	45
AH-SHA-HMAC or MD5	44

Authentication

To protect data via encryption, a VPN must ensure that only authorized users can access the private network. You must use either a preshared key on both VPN gateways or RSA X.509 security certificates. The examples in this guide use only preshared key authentication. Refer to the [Fortinet Knowledge Base](#) for articles on RSA X.509 security certificates.

Preshared keys

A preshared key contains at least six random alphanumeric characters. Users of the VPN must obtain the preshared key from the person who manages the VPN server and add the preshared key to their VPN client configuration.

Although it looks like a password, the preshared key, also known as a shared secret, is never sent by either gateway. The preshared key is used in the calculations at each end that generate the encryption keys. As soon as the VPN peers attempt to exchange encrypted data, preshared keys that do not match will cause the process to fail.

Additional authentication

To increase security, you can require additional means of authentication from users, such as:

- An identifier, called a peer ID or a local ID.
- Extended authentication (XAUTH) which imposes an additional user name/password requirement.

A Local ID is an alphanumeric value assigned in the Phase 1 configuration. The Local ID of a peer is called a Peer ID.

In FortiOS 5.2, new authentication methods have been implemented for IKE: ECDSA-256, ECDSA-384, and ECDSA-521. However, AES-XCBC is not supported.

Phase 1 and Phase 2 settings

A VPN tunnel is established in two phases: Phase 1 and Phase 2. Several parameters determine how this is done. Except for IP addresses, the settings simply need to match at both VPN gateways. There are defaults that are appropriate for most cases.

FortiClient distinguishes between Phase 1 and Phase 2 only in the VPN Advanced settings and uses different terms. Phase 1 is called the IKE Policy. Phase 2 is called the IPsec Policy.

Phase 1

In Phase 1, the two VPN gateways exchange information about the encryption algorithms that they support and then establish a temporary secure connection to exchange authentication information.

When you configure your FortiGate unit or FortiClient application, you must specify the following settings for Phase 1:

Remote gateway	The remote VPN gateway's address. FortiGate units also have the option of operating only as a server by selecting the "Dialup User" option.
Preshared key	This must be the same at both ends. It is used to encrypt Phase 1 authentication information.
Local interface	The network interface that connects to the other VPN gateway. This applies on a FortiGate unit only.

All other Phase 1 settings have default values. These settings mainly configure the types of encryption to be used. The default settings on FortiGate units and in the FortiClient application are compatible. The examples in this guide use these defaults.

For more detailed information about Phase 1 settings, see [Phase 1 parameters on page 2048](#).

Phase 2

Similar to the Phase 1 process, the two VPN gateways exchange information about the encryption algorithms that they support for Phase 2. You may choose different encryption for Phase 1 and Phase 2. If both gateways have at least one encryption algorithm in common, a VPN tunnel can be established. Keep in mind that more algorithms each phase does not share with the other gateway, the longer negotiations will take. In extreme cases this may cause timeouts during negotiations.

To configure default Phase 2 settings on a FortiGate unit, you need only select the name of the corresponding Phase 1 configuration. In FortiClient, no action is required to enable default Phase 2 settings.

For more detailed information about Phase 2 settings, see [Phase 2 parameters on page 2067](#).

Security Association

The establishment of a Security Association (SA) is the successful outcome of Phase 1 negotiations. Each peer maintains a database of information about VPN connections. The information in each SA can include cryptographic algorithms and keys, keylife, and the current packet sequence number. This information is kept synchronized as the VPN operates. Each SA has a Security Parameter Index (SPI) that is provided to the remote peer at the time the SA is established. Subsequent IPsec packets from the peer always reference the relevant SPI. It is possible for peers to have multiple VPNs active simultaneously, and correspondingly multiple SPIs.

The IPsec SA connect message generated is used to install dynamic selectors. These selectors can be installed via the auto-negotiate mechanism. When phase 2 has auto-negotiate enabled, and phase 1 has mesh selector-type set to **subnet**, a new dynamic selector will be installed for each combination of source and destination

subnets. Each dynamic selector will inherit the auto-negotiate option from the template selector and begin SA negotiation. Phase 2 selector sources from dial-up clients will all establish SAs without traffic being initiated from the client subnets to the hub.

Remote IP address change detection

SAs are stored in a hash table when keyed off the IPsec SA SPI value. This enables the FortiGate, for each inbound ESP packet received, to immediately look up the SA and compare the stored IP address against the one in the incoming packet. If the incoming and stored IP addresses differ, an IP address change can be made in the kernel SA, and an update event can be triggered for IKE.

IKE and IPsec packet processing

Internet Key Exchange (IKE) is the protocol used to set up SAs in IPsec negotiation. As described in [Phase 1 parameters on page 2048](#), you can optionally choose IKEv2 over IKEv1 if you configure a route-based IPsec VPN. IKEv2 simplifies the negotiation process, in that it provides no choice of Aggressive or Main mode in Phase 1. IKEv2 also uses less bandwidth.

The following sections identify how IKE versions 1 and 2 operate and differentiate.

IKEv1

Phase 1

A peer, identified in the IPsec policy configuration, begins the IKE negotiation process. This IKE Security Association (SA) agreement is known as Phase 1. The Phase 1 parameters identify the remote peer or clients and supports authentication through pre-shared key (PSK) or digital certificate. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes. Basically, Phase 1 authenticates a remote peer and sets up a secure communication channel for establishing Phase 2, which negotiates the IPsec SA.

IKE Phase 1 can occur in either Main mode or Aggressive mode. For more information, see [Phase 1 parameters on page 2048](#).

IKE Phase 1 is successful only when the following are true:

- Each peer negotiates a matching IKE SA policy.
- Each peer is authenticated and their identities protected.
- The Diffie-Hellman exchange is authenticated (the pre-shared secret keys match).

For more information on Phase 1, see [Phase 1 parameters on page 2048](#).

Phase 2

Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session in an IPsec SA. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a more secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of the SA. The keys are generated automatically using a Diffie-Hellman algorithm.

In Phase 2, Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure. For more information, see [Phase 2 parameters on page 2067](#).

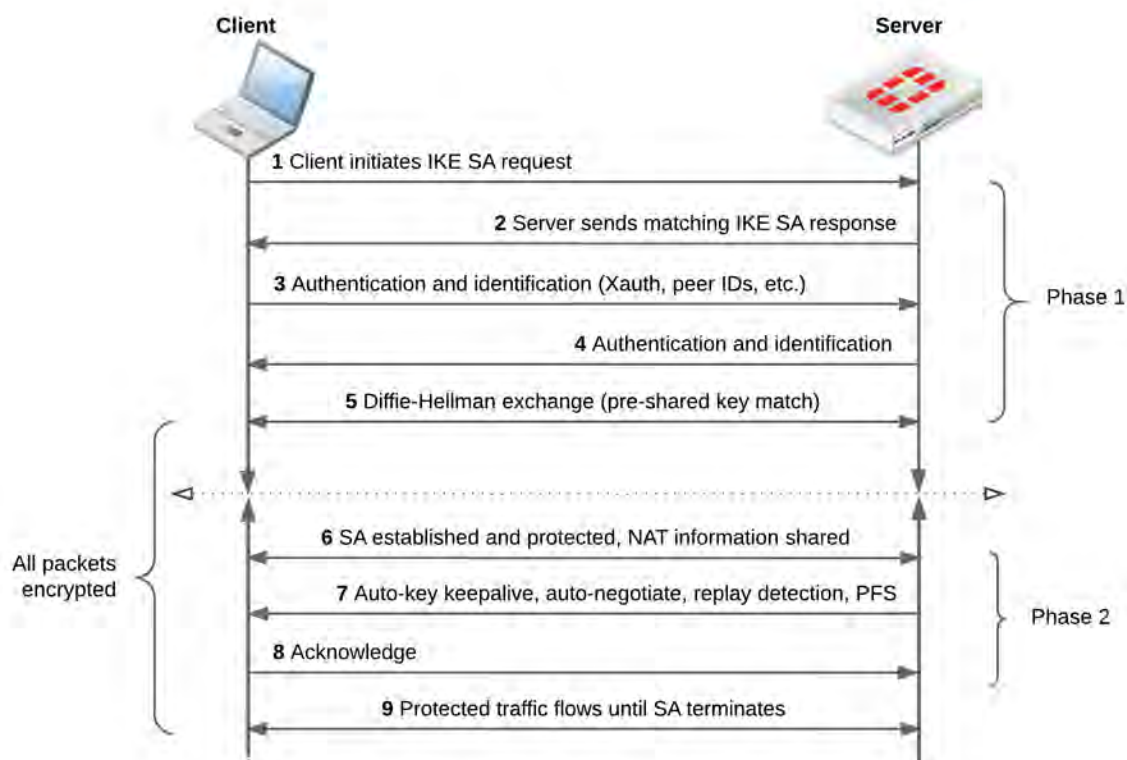

IKE Phase 2 is successful only when the following are true:

- The IPsec SA is established and protected by the IKE SA.
- The IPsec SA is configured to renegotiate after set durations (see [Phase 2 parameters on page 2067](#) and [Phase 2 parameters on page 2067](#)).
- **Optional:** Replay Detection is enabled. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel. See [Phase 2 parameters on page 2067](#).
- **Optional:** Perfect Forward Secrecy (PFS) is enabled. PFS improves security by forcing a new Diffie-Hellman exchange whenever keylife expires. See [Phase 2 parameters on page 2067](#).

For more information on Phase 2, see [Phase 2 parameters on page 2067](#).

With Phase 2 established, the IPsec tunnel is fully negotiated and traffic between the peers is allowed until the SA terminates (for any number of reasons; time-out, interruption, disconnection, etc).

The entire IKEv1 process is demonstrated in the following diagram:

IKEv2

Phase 1

Unlike Phase 1 of IKEv1, IKEv2 does not provide options for Aggressive or Main mode. Furthermore, Phase 1 of IKEv2 begins immediately with an IKE SA initiation, consisting of only two packets (containing all the information

typically contained in four packets for IKEv1), securing the channel such that all following transactions are encrypted (see [Phase 1 parameters on page 2048](#)).

The encrypted transactions contain the IKE authentication, since remote peers have yet to be authenticated. This stage of IKE authentication in IKEv2 can loosely be called Phase 1.5.

Phase 1.5

As part of this phase, IKE authentication must occur. IKE authentication consists of the following:

- The authentication payloads and Internet Security Association and Key Management Protocol (ISAKMP) identifier.
- The authentication method (RSA, PSK, ECDSA, or EAP).
- The IPsec SA parameters.

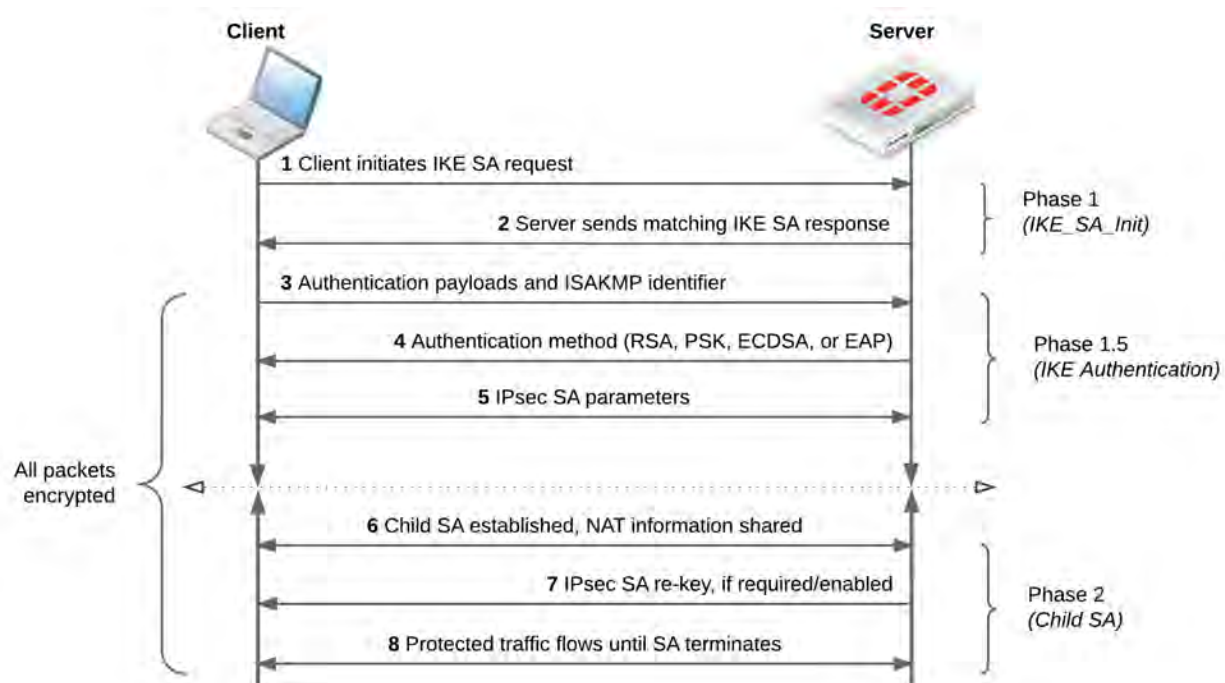

Due to the number of authentication methods potentially used, and SAs established, the overall IKEv2 negotiation can range from 4 packets (no EAP exchange at all) to many more.

At this point, both peers have a security association complete and ready to encrypt traffic.

Phase 2

In IKEv1, Phase 2 uses Quick mode to negotiate an IPsec SA between peers. In IKEv2, since the IPsec SA is already established, Phase 2 is essentially only used to negotiate “child” SAs, or to re-key an IPsec SA. That said, there are only two packets for each exchange of this type, similar to the exchange at the outset of Phase 1.5.

The entire IKEv2 process is demonstrated in the following diagram:

Support for IKEv2 session resumption

If a gateway loses connectivity to the network, clients can attempt to re-establish the lost session by presenting the ticket to the gateway (as described in [RFC 5723](#)). As a result, sessions can be resumed much faster, as DH

exchange that is necessary to establish a brand new connection is skipped. This feature implements "ticket-by-value", whereby all information necessary to restore the state of a particular IKE SA is stored in the ticket and sent to the client.

IKEv2 asymmetric authentication

Asymmetric authentication allows both sides of an authentication exchange to use different authentication methods, for example the initiator may be using a shared key, while the responder may have a public signature key and certificate.

The command `authmethod-remote` is available under `config vpn ipsec phase1-interface`.

For more detailed information on authentication of the IKE SA, see [RFC 5996 - Internet Key Exchange Protocol Version 2 \(IKEv2\)](#).

IKEv2 Digital Signature Authentication support

FortiOS supports the use of Digital Signature authentication, which changes the format of the Authentication Data payload in order to support different signature methods.

Instead of just containing a raw signature value calculated as defined in the original IKE RFCs, the Auth Data now includes an ASN.1 formatted object that provides details on how the signature was calculated, such as the signature type, hash algorithm, and signature padding method.

For more detailed information on IKEv2 Digital Signature authentication, see [RFC 7427 - Signature Authentication in the Internet Key Exchange Version 2 \(IKEv2\)](#).

Unique IKE identifiers

When enabled, the following `phase1` CLI command (`enforce-unique-id`) requires all IPsec VPN clients to use a unique identifier when connecting.

CLI syntax

```
config vpn ipsec phase1
  edit <name>
    set enforce-unique-id {keep-new | keep-old | disable} Default is disable.
  next
end
```

Use `keep-new` to replace the old connection if an ID collision is detected on the gateway.

Use `keep-old` to reject the new connection if an ID collision is detected.

IKEv2 ancillary RADIUS group authentication

This feature provides for the IDi information to be extracted from the IKEv2 AUTH exchange and sent to a RADIUS server, along with a fixed password (configurable via CLI only), to perform an additional group authentication step prior to tunnel establishment. The RADIUS server may return framed-ip-address, framed-ip-netmask, and dns-server attributes, which are then applied to the tunnel.

It should be noted, unlike Xauth or EAP, this feature does not perform individual user authentication, but rather treats all users on the gateway as a single group, and authenticates that group with RADIUS using a fixed password. This feature also works with RADIUS accounting, including the `phase1 acct-verify` option.

Syntax

```
config vpn ipsec phase1-interface
  edit <name>
    set mode-cfg enable
    set type dynamic
    set ike-version 2
    set group-authentication {enable | disable}
    set group-authentication-secret <password>
  next
end
```

IPsec VPN overview

This section provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

The following topics are included in this section:

VPN configurations interact with the firewall component of the FortiGate unit. There must be a security policy in place to permit traffic to pass between the private network and the VPN tunnel.

Security policies for VPNs specify:

- The FortiGate interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- The FortiGate interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- Optionally, a schedule that restricts when the VPN can operate
- Optionally, the services (types of data) that can be sent

When the first packet of data that meets all of the conditions of the security policy arrives at the FortiGate unit, a VPN tunnel may be initiated and the encryption or decryption of data is performed automatically afterward. For more information, see [Defining VPN security policies on page 1](#).

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Types of VPNs

FortiGate unit VPNs can be policy-based or route-based. There is little difference between the two types. In both cases, you specify Phase 1 and Phase 2 settings. However there is a difference in implementation. A route-based VPN creates a virtual IPsec network interface that applies encryption or decryption as needed to any traffic that it carries. That is why route-based VPNs are also known as interface-based VPNs. A policy-based VPN is implemented through a special security policy that applies the encryption you specified in the Phase 1 and Phase 2 settings.

Route-based VPNs

For a route-based VPN, you create two security policies between the virtual IPsec interface and the interface that connects to the private network. In one policy, the virtual interface is the source. In the other policy, the virtual interface is the destination. This creates bidirectional policies that ensure traffic will flow in both directions over the VPN.

A route-based VPN is also known as an interface-based VPN.

Each route-based IPsec VPN tunnel requires a virtual IPsec interface. As such, the amount of possible route-based IPsec VPNs is limited by the **system.interface** table size. The **system.interface** table size for most devices is 8192.

For a complete list of table sizes for all devices, refer to the [Maximum Values](#) table.

Policy-based VPNs

For a policy-based VPN, one security policy enables communication in both directions. You enable inbound and outbound traffic as needed within that policy, or create multiple policies of this type to handle different types of traffic differently. For example HTTPS traffic may not require the same level of scanning as FTP traffic.

A policy-based VPN is also known as a tunnel-mode VPN.

Comparing policy-based or route-based VPNs

For both VPN types you create Phase 1 and Phase 2 configurations. Both types are handled in the stateful inspection security layer, assuming there is no IPS or AV.

The main difference is in the security policy.

You create a policy-based VPN by defining an IPSEC security policy between two network interfaces and associating it with the VPN tunnel (Phase 1) configuration.

You create a route-based VPN by creating a virtual IPsec interface. You then define a regular ACCEPT security policy to permit traffic to flow between the virtual IPsec interface and another network interface. And lastly, configure a static route to allow traffic over the VPN.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Comparison of policy-based and route-based VPNs

Features	Policy-based	Route-based
Both NAT and transparent modes available	Yes	NAT mode only
L2TP-over-IPsec supported	Yes	Yes
GRE-over-IPsec supported	No	Yes
security policy requirements	Requires a security policy with IPSEC action that specifies the VPN tunnel	Requires only a simple security policy with ACCEPT action
Number of policies per VPN	One policy controls connections in both directions	A separate policy is required for connections in each direction

Planning your VPN

It is a good idea to plan the VPN configuration ahead of time. This will save time later and help you configure your VPN correctly.

All VPN configurations are comprised of numerous required and optional parameters. Before you begin, you need to determine:

- Where the IP traffic originates and where it needs to be delivered
- Which hosts, servers, or networks to include in the VPN
- Which VPN devices to include in the configuration
- Through which interfaces the VPN devices communicate
- Through which interfaces do private networks access the VPN gateways

Once you have this information, you can select a VPN topology that suits the network environment.

Network topologies

The topology of your network will determine how remote peers and clients connect to the VPN and how VPN traffic is routed.

VPN network topologies and brief descriptions

Topology	Description
Gateway-to-gateway configurations	Standard one-to-one VPN between two FortiGate units. See Gateway-to-gateway configurations on page 1 .
Hub-and-spoke configurations	One central FortiGate unit has multiple VPNs to other remote FortiGate units. See Hub-and-spoke configurations on page 1 .
Dynamic DNS configuration	One end of the VPN tunnel has a changing IP address and the other end must go to a dynamic DNS server for the current IP address before establishing a tunnel. See Dynamic DNS configuration on page 1 .
FortiClient dialup-client configurations	Typically remote FortiClient dialup-clients use dynamic IP addresses through NAT devices. The FortiGate unit acts as a dialup server allowing dialup VPN connections from multiple sources. See FortiClient dialup-client configurations on page 1 .
FortiGate dialup-client configurations	Similar to FortiClient dialup-client configurations but with more gateway-to-gateway settings such as unique user authentication for multiple users on a single VPN tunnel. See FortiGate dialup-client configurations on page 1 .
Internet-browsing configuration	Secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. See Internet-browsing configuration on page 1 .
Redundant VPN configurations	Options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches. See Redundant VPN configurations on page 1 .
Transparent mode VPNs	In transparent mode, the FortiGate acts as a bridge with all incoming traffic being broadcast back out on all other interfaces. Routing and NAT must be performed on external routers. See Transparent mode VPNs on page 1 .
L2TP and IPsec (Microsoft VPN)	Configure VPN for Microsoft Windows dialup clients using the built in L2TP software. Users do not have to install any See L2TP and IPsec (Microsoft VPN) on page 1 .

These sections contain high-level configuration guidelines with cross-references to detailed configuration procedures. If you need more detail to complete a step, select the cross-reference in the step to drill-down to more detail. Return to the original procedure to complete the procedure. For a general overview of how to configure a VPN, see [Planning your VPN](#).

General preparation steps

A VPN configuration defines relationships between the VPN devices and the private hosts, servers, or networks making up the VPN. Configuring a VPN involves gathering and recording the following information. You will need this information to configure the VPN.

- **The private IP addresses of participating hosts, servers, and/or networks.** These IP addresses represent the source addresses of traffic that is permitted to pass through the VPN. A IP source address can be an individual IP address, an address range, or a subnet address.
- **The public IP addresses of the VPN end-point interfaces.** The VPN devices establish tunnels with each other through these interfaces.
- **The private IP addresses associated with the VPN-device interfaces to the private networks.** Computers on the private networks behind the VPN gateways will connect to their VPN gateways through these interfaces.

How to use this guide to configure an IPsec VPN

This guide uses a task-based approach to provide all of the procedures needed to create different types of VPN configurations. Follow the step-by-step configuration procedures in this guide to set up the VPN.

The following configuration procedures are common to all IPsec VPNs:

1. Define the Phase 1 parameters that the FortiGate unit needs to authenticate remote peers or clients and establish a secure connection. See [Phase 1 parameters on page 2048](#).
2. Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with a remote peer or dialup client. See [Phase 2 parameters on page 2067](#).
3. Specify the source and destination addresses of IP packets that are to be transported through the VPN tunnel. See [Defining policy addresses on page 1](#).
4. Create an IPsec security policy to define the scope of permitted services between the IP source and destination addresses. See [Defining VPN security policies on page 1](#).

These steps assume you configure the FortiGate unit to generate unique IPsec encryption and authentication keys automatically. In situations where a remote VPN peer or client requires a specific IPsec encryption and authentication key, you must configure the FortiGate unit to use manual keys instead of performing Steps 1 and 2.

IPsec VPN in the web-based manager

To configure an IPsec VPN, use the general procedure below. With these steps, your FortiGate unit will automatically generate unique IPsec encryption and authentication keys. If a remote VPN peer or client requires a specific IPsec encryption or authentication key, you must configure your FortiGate unit to use manual keys instead.

1. Define Phase 1 parameters to authenticate remote peers and clients for a secure connection. See [IPsec VPN in the web-based manager on page 2035](#).
2. Define Phase 2 parameters to create a VPN tunnel with a remote peer or dialup client. See [IPsec VPN in the web-based manager on page 2035](#).
3. Create a security policy to permit communication between your private network and the VPN. Policy-based VPNs have an action of IPSEC, where for interface-based VPNs the security policy action is ACCEPT. See [Defining VPN security policies on page 1](#).

The FortiGate unit implements the Encapsulated Security Payload (ESP) protocol. Internet Key Exchange (IKE) is performed automatically based on pre-shared keys or X.509 digital certificates. Interface mode, supported in NAT mode only, creates a virtual interface for the local end of a VPN tunnel.

This chapter contains the following sections:

Phase 1 configuration

To begin defining the Phase 1 configuration, go to **VPN > IPsec Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

If you want to control how the IKE negotiation is processed when there is no traffic, as well as the length of time the FortiGate unit waits for negotiations to occur, you can use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

For more information, refer to [Phase 2 parameters on page 2067](#) and [Phase 2 parameters on page 2067](#).

Name	Type a name for the Phase 1 definition. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN. If Remote Gateway is Dialup User , the maximum name length is further reduced depending on the number of dialup tunnels that can be established: by 2 for up to 9 tunnels, by 3 for up to 99 tunnels, 4 for up to 999 tunnels, and so on. For a tunnel mode VPN, the name normally reflects where the remote connection originates. For a route-based tunnel, the FortiGate unit also uses the name for the virtual IPsec interface that it creates automatically.
-------------	---

Select the category of the remote connection:	
Remote Gateway	<p>Static IP Address — If the remote peer has a static IP address.</p> <p>Dialup User — If one or more FortiClient or FortiGate dialup clients with dynamic IP addresses will connect to the FortiGate unit.</p> <p>Dynamic DNS — If a remote peer that has a domain name and subscribes to a dynamic DNS service will connect to the FortiGate unit.</p>
IP Address	If you selected Static IP Address , enter the IP address of the remote peer.
Dynamic DNS	If you selected Dynamic DNS , enter the domain name of the remote peer.
Local Interface	<p>This option is available in NAT mode only. Select the name of the interface through which remote peers or dialup clients connect to the FortiGate unit.</p> <p>By default, the local VPN gateway IP address is the IP address of the interface that you selected.</p>
Mode	<p>Main mode — the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</p> <p>Aggressive mode — the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</p> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a pre-shared key, you must select Aggressive mode if there is more than one dialup phase1 configuration for the interface IP address.</p> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a certificate, you must select Aggressive mode if there is more than one Phase 1 configuration for the interface IP address and these Phase 1 configurations use different proposals.</p>
Authentication Method	Select Preshared Key or RSA Signature .
Pre-shared Key	<p>If you selected Pre-shared Key, enter the pre-shared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same key at the remote peer or client.</p> <p>The key must contain at least 6 printable characters. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters. The limit is 128 characters.</p>
Certificate Name	If you selected RSA Signature , select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations.

Peer Options	Peer options are available to authenticate VPN peers or clients, depending on the Remote Gateway and Authentication Method settings.
Any peer ID	<p>Accept the local ID of any remote VPN peer or client. The FortiGate unit does not check identifiers (local IDs). You can set Mode to Aggressive or Main.</p> <p>You can use this option with RSA Signature authentication. But, for highest security, configure a PKI user/group for the peer and set Peer Options to Accept this peer certificate only.</p>
This peer ID	<p>This option is available when Aggressive Mode is enabled. Enter the identifier that is used to authenticate the remote peer. This identifier must match the Local ID that the remote peer's administrator has configured.</p> <p>If the remote peer is a FortiGate unit, the identifier is specified in the Local ID field of the Advanced Phase 1 configuration.</p> <p>If the remote peer is a FortiClient user, the identifier is specified in the Local ID field, accessed by selecting Config in the Policy section of the VPN connection's Advanced Settings.</p> <p>In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.</p>
Peer ID from dialup group	<p>Authenticate multiple FortiGate or FortiClient dialup clients that use unique identifiers and unique pre-shared keys (or unique pre-shared keys only) through the same VPN tunnel.</p> <p>You must create a dialup user group for authentication purposes. Select the group from the list next to the Peer ID from dialup group option.</p> <p>You must set Mode to Aggressive when the dialup clients use unique identifiers and unique pre-shared keys. If the dialup clients use unique pre-shared keys only, you can set Mode to Main if there is only one dialup Phase 1 configuration for this interface IP address.</p>

Phase 1 advanced configuration settings

You can use the following advanced parameters to select the encryption and authentication algorithms that the FortiGate unit uses to generate keys for the IKE exchange. You can also use the following advanced parameters to ensure the smooth operation of Phase 1 negotiations.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, set the **Local ID** to the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes.

Note that, since FortiOS 5.4, an exact match is required to optimize IKE's gateway search utilizing binary trees. However, it is also possible to have partial matching of 'user.peer:cn' to match peers to gateways by performing a secondary match. When IKE receives IDi of type ASN1.DN, the first search is done with the whole DN string. If none is found, IKE will extract just the CN attribute value and perform a second search.

VXLAN over IPsec

Packets with VXLAN header are encapsulated within IPsec tunnel mode.

To configure VXLAN over IPsec - CLI:

```
config vpn ipsec phase1-interface/phase1
edit ipsec
set interface <name>
set encapsulation vxlan/gre
set encapsulation-address ike/ipv4/ipv6
set encap-local-gw4 xxx.xxx.xxx.xxx
set encap-remote-gw xxx.xxx.xxx.xxx
next
end
```

You can define an idle timer for IPsec tunnels. When no traffic has passed through the tunnel for the configured idle-timeout value, the IPsec tunnel will be flushed.

To configure IPsec tunnel idle timeout - CLI:

IPsec tunnel idle timer

```
config vpn ipsec phase1-interface
edit p1
set idle-timeout [enable | disable]
set idle-timeoutinterval <integer> //IPsec tunnel
idle timeout in minutes (10 - 43200).
end
end
```

IPv6 Version

Select if you want to use IPv6 addresses for the remote gateway and interface IP addresses.

Specify an IP address for the local end of the VPN tunnel. Select one of the following:

Local Gateway IP

Main Interface IP — The FortiGate unit obtains the IP address of the interface from the network interface settings.

Specify — Enter a secondary address of the interface selected in the Phase 1 **Local Interface** field.

You cannot configure Interface mode in a transparent mode VDOM.

Phase 1 Proposal	<p>Select the encryption and authentication algorithms used to generate keys for protecting negotiations and add encryption and authentication algorithms as required.</p> <p>You need to select a minimum of one and a maximum of three combinations. The remote peer or client must be configured to use at least one of the proposals that you define.</p> <p>Select one of the following symmetric-key encryption algorithms:</p> <p>DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</p> <p>3DES — Triple-DES; plain text is encrypted three times by three keys.</p> <p>AES128 — A 128-bit block algorithm that uses a 128-bit key.</p> <p>AES192 — A 128-bit block algorithm that uses a 192-bit key.</p> <p>AES256 — A 128-bit block algorithm that uses a 256-bit key.</p> <p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>MD5 — Message Digest 5.</p> <p>SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p>
Diffie-Hellman Group	<p>Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, and 14 through 21. At least one of the Diffie-Hellman Group settings on the remote peer or client must match one the selections on the FortiGate unit. Failure to match one or more DH groups will result in failed negotiations.</p>
Keylife	<p>Enter the time (in seconds) that must pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172 800 seconds.</p>

Local ID	<p>If the FortiGate unit will act as a VPN client and you are using peer IDs for authentication purposes, enter the identifier that the FortiGate unit will supply to the VPN server during the Phase 1 exchange.</p> <p>If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, select the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes.</p> <p>If the FortiGate unit is a dialup client and will not be sharing a tunnel with other dialup clients (that is, the tunnel will be dedicated to this Fortinet dialup client), set Mode to Aggressive.</p> <p>Note that this Local ID value must match the peer ID value given for the remote VPN peer's Peer Options.</p>
XAuth	<p>This option supports the authentication of dialup clients. It is available for IKE v1 only.</p> <p>Disable — Select if you do not use XAuth.</p> <p>Enable as Client — If the FortiGate unit is a dialup client, enter the user name and password that the FortiGate unit will need to authenticate itself to the remote XAuth server.</p> <p>Enable as Server — This is available only if Remote Gateway is set to Dialup User. Dialup clients authenticate as members of a dialup user group. You must first create a user group for the dialup clients that need access to the network behind the FortiGate unit.</p> <p>You must also configure the FortiGate unit to forward authentication requests to an external RADIUS or LDAP authentication server.</p> <p>Select a Server Type setting to determine the type of encryption method to use between the FortiGate unit, the XAuth client and the external authentication server, and then select the user group from the User Group list.</p>
Username	Enter the user name that is used for authentication.
Password	Enter the password that is used for authentication.

NAT Traversal

Select the check box if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared) to connect reliably.

Additionally, you can force IPsec to use NAT traversal. If NAT is set to **Forced**, the FortiGate will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

Keepalive Frequency

If you enabled **NAT-traversal**, enter a keepalive frequency setting.

Dead Peer Detection

Select this check box to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. You can use this option to receive notification whenever a tunnel goes up or down, or to keep the tunnel connection open when no traffic is being generated inside the tunnel. For example, in scenarios where a dialup client or dynamic DNS peer connects from an IP address that changes periodically, traffic may be suspended while the IP address changes.

With **Dead Peer Detection** selected, you can use the `config vpn ipsec phase1` (tunnel mode) or `config vpn ipsec phase1-interface` (interface mode) CLI command to optionally specify a retry count and a retry interval.

IKEv1 fragmentation

UDP fragmentation can cause issues in IPsec when either the ISP or perimeter firewall(s) cannot pass or fragment the oversized UDP packets that occur when using a very large public security key (PSK). The result is that IPsec tunnels do not come up. The solution is IKE fragmentation.

For most configurations, enabling IKE fragmentation allows connections to automatically establish when they otherwise might have failed due to intermediate nodes dropping IKE messages containing large certificates, which typically push the packet size over 1500 bytes.

FortiOS will fragment a packet on sending if, and only if, all the following are true:

- Phase 1 contains "set fragmentation enable".
- The packet is larger than the minimum MTU (576 for IPv4, 1280 for IPv6).
- The packet is being re-transmitted.

By default, IKE fragmentation is enabled, but upon upgrading, any existing phase1-interface may have have "set fragmentation disable" added in order to preserve the existing behaviour of not supporting fragmentation.

Enabling or disabling IKE fragmentation - CLI

```
config vpn ipsec phase1-interface
  edit 1
    set fragmentation [enable | disable]
  next
end
```

IKEv2 fragmentation

With IKEv2, because [RFC 7383](#) requires each fragment to be individually encrypted and authenticated, we would have to keep a copy of the unencrypted payloads around for each outgoing packet, in case the original single packet was never answered and we wanted to retry with fragments. With the following implementation, if the IKE payloads are greater than a configured threshold, the IKE packets are preemptively fragmented and encrypted.

CLI syntax

```
config vpn ipsec phase1-interface
    edit ike
        set ike-version 2
        set fragmentation [enable|disable]
        set fragmentation-mtu [500-16000]
    next
end
```

Phase 2 configuration

After IPsec Phase 1 negotiations end successfully, you begin Phase 2. You can configure the Phase 2 parameters to define the algorithms that the FortiGate unit may use to encrypt and transfer data for the remainder of the session. During Phase 2, you select specific IPsec security associations needed to implement security services and establish a tunnel.

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration that specifies the remote end point of the VPN tunnel. In most cases, you need to configure only basic Phase 2 settings.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

Name	Type a name to identify the Phase 2 configuration.
Phase 1	Select the Phase 1 tunnel configuration. For more information on configuring Phase 1, see Phase 1 configuration on page 2035 . The Phase 1 configuration describes how remote VPN peers or clients will be authenticated on this tunnel, and how the connection to the remote peer or client will be secured.
Advanced	Define advanced Phase 2 parameters. For more information, see Phase 2 advanced configuration settings below.

Phase 2 advanced configuration settings

In Phase 2, the FortiGate unit and the VPN peer or client exchange keys again to establish a secure communication channel between them. You select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). These are called Phase 2 Proposal parameters. The keys are generated automatically using a Diffie-Hellman algorithm.

You can use a number of additional advanced Phase 2 settings to enhance the operation of the tunnel.

Phase 2 Proposal	<p>Select the encryption and authentication algorithms that will be proposed to the remote VPN peer. You can specify up to three proposals. To establish a VPN connection, at least one of the proposals that you specify must match configuration on the remote peer.</p> <p>Initially there are two proposals. Add and Delete icons are next to the second Authentication field.</p> <p>It is invalid to set both Encryption and Authentication to NULL.</p>
Encryption	<p>Select a symmetric-key algorithms:</p> <p>NULL — Do not use an encryption algorithm. DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. 3DES — Triple-DES; plain text is encrypted three times by three keys. AES128 — A 128-bit block algorithm that uses a 128-bit key. AES192 — A 128-bit block algorithm that uses a 192-bit key. AES256 — A 128-bit block algorithm that uses a 256-bit key.</p>
Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest. MD5 — Message Digest 5. SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p>
Enable replay detection	<p>Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.</p>
Enable perfect forward secrecy (PFS)	<p>Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.</p>
Diffie-Hellman Group	<p>Select one Diffie-Hellman group (1, 2, 5, or 14 through 21). This must match the DH Group that the remote peer or dialup client uses.</p>
Keylife	<p>Select the method for determining when the Phase 2 key expires: Seconds, KBytes, or Both. If you select Both, the key expires when either the time has passed or the number of KB have been processed.</p>
Autokey Keep Alive	<p>Select the check box if you want the tunnel to remain active when no data is being processed.</p>
Auto-negotiate	<p>Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.</p>

DHCP-IPsec

Provide IP addresses dynamically to VPN clients. This is available for Phase 2 configurations associated with a dialup Phase 1 configuration.

You also need configure a DHCP server or relay on the private network interface. You must configure the DHCP parameters separately.

If you configure the DHCP server to assign IP addresses based on RADIUS user group attributes, you must also set the Phase 1 **Peer Options** to **Peer ID from dialup group** and select the appropriate user group. See [Phase 1 configuration on page 2035](#).

If the FortiGate unit acts as a dialup server and you manually assigned FortiClient dialup clients VIP addresses that match the network behind the dialup server, selecting the check box will cause the FortiGate unit to act as a proxy for the dialup clients.

Quick Mode Selector

Specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value of 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and a protocol number.

If you are editing an existing Phase 2 configuration, the **Source address** and **Destination address** fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI.

Source address

If the FortiGate unit is a dialup server, enter the source IP address that corresponds to the local senders or network behind the local VPN peer (for example, 172.16.5.0/24 or 172.16.5.0/255.255.255.0 for a subnet, or 172.16.5.1/32 or 172.16.5.1/255.255.255.255 for a server or host, or 192.168.10.[80-100] or 192.168.10.80-192.168.10.100 for an address range). A value of 0.0.0.0/0 means all IP addresses behind the local VPN peer.

If the FortiGate unit is a dialup client, source address must refer to the private network behind the Fortinet dialup client.

Source port

Enter the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is from 0 to 65535. To specify all ports, type 0.

Destination address

Enter the destination IP address that corresponds to the recipients or network behind the remote VPN peer (for example, 192.168.20.0/24 for a subnet, or 172.16.5.1/32 for a server or host, or 192.168.10.[80-100] for an address range). A value of 0.0.0.0/0 means all IP addresses behind the remote VPN peer.

Destination port	Enter the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). To specify all ports, enter 0.
Protocol	Enter the IP protocol number of the service. To specify all services, enter 0.

FortiClient VPN

Use the **FortiClient VPN for OS X, Windows, and Android** VPN Wizard option when configuring an IPsec VPN for remote users to connect to the VPN tunnel using FortiClient.

When configuring a FortiClient VPN connection, the settings for Phase 1 and Phase 2 settings are automatically configured by the FortiGate unit. They are set to:

- Remote Gateway — Dialup User
- Mode — Aggressive
- Default settings for Phase 1 and 2 Proposals
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option — “Any peer ID”

The remainder of the settings use the current FortiGate defaults. Note that FortiClient settings need to match these FortiGate defaults. If you need to configure advanced settings for the FortiClient VPN, you must do so using the CLI.

Name	Enter a name for the FortiClient VPN.
Local Outgoing Interface	Select the local outgoing interface for the VPN.
Authentication Method	Select the type of authentication used when logging in to the VPN.
Preshared Key	If Pre-shared Key was selected in Authentication Method , enter the pre-shared key in the field provided.
User Group	Select a user group. You can also create a user group from the drop-down list by selecting Create New .
Address Range Start IP	Enter the start IP address for the DHCP address range for the client.
Address Range End IP	Enter the end IP address for the address range.
Subnet Mask	Enter the subnet mask.
Enable IPv4 Split Tunnel	Enabled by default, this option enables the FortiClient user to use the VPN to access internal resources while other Internet access is not sent over the VPN, alleviating potential traffic bottlenecks in the VPN connection. Disable this option to have all traffic sent through the VPN tunnel.
Accessible Networks	Select from a list of internal networks that the FortiClient user can access.

Client Options	<p>These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default.</p> <p>Save Password - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN.</p> <p>Auto Connect - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel.</p> <p>Always Up (Keep Alive) - When enabled, if the user selects this option, the FortiClient connection will not shut down. When not selected, during periods of inactivity, FortiClient will attempt to stay connected every three minutes for a maximum of 10 minutes.</p>
Endpoint Registration	<p>When selected, the FortiGate unit requests a registration key from FortiClient before a connection can be established. A registration key is defined by going to System > Advanced.</p> <p>For more information on FortiClient VPN connections to a FortiGate unit, see the FortiClient Administration Guide.</p>
DNS Server	<p>Select which DNS server to use for this VPN:</p> <p>Use System DNS — Use the same DNS servers as the FortiGate unit. These are configured at Network > DNS. This is the default option.</p> <p>Specify — Specify the IP address of a different DNS server.</p>

Concentrator

In a hub-and-spoke configuration, policy-based VPN connections to a number of remote peers radiate from a single, central FortiGate unit. Site-to-site connections between the remote peers do not exist; however, you can establish VPN tunnels between any two of the remote peers through the FortiGate unit's "hub".

In a hub-and-spoke network, all VPN tunnels terminate at the hub. The peers that connect to the hub are known as "spokes". The hub functions as a concentrator on the network, managing all VPN connections between the spokes. VPN traffic passes from one tunnel to the other through the hub.

You define a concentrator to include spokes in the hub-and-spoke configuration. You create the concentrator in **VPN > IPsec Concentrator** and select **Create New**. A concentrator configuration specifies which spokes to include in an IPsec hub-and-spoke configuration.

Concentrator Name	Type a name for the concentrator.
Available Tunnels	A list of defined IPsec VPN tunnels. Select a tunnel from the list and then select the right arrow.

Members

A list of tunnels that are members of the concentrator. To remove a tunnel from the concentrator, select the tunnel and select the left arrow.

IPsec Monitor

You can use the IPsec Monitor to view activity on IPsec VPN tunnels and start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels, including tunnel mode and route-based (interface mode) tunnels.

To view the IPsec monitor, go to **Monitor > IPsec Monitor**.

Tunnels are considered as "up" if at least one phase 2 selector is active. To avoid confusion, when a tunnel is down, **IPsec Monitor** will keep the **Phase 2 Selectors** column, but hide it by default and be replaced with **Phase 1** status column.

For dialup VPNs, the list provides status information about the VPN tunnels established by dialup clients, and their IP addresses.

For static IP or dynamic DNS VPNs, the list provides status and IP addressing information about VPN tunnels, active or not, to remote peers that have static IP addresses or domain names. You can also start and stop individual tunnels from the list.

Phase 1 parameters

This chapter provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The Phase 1 parameters identify the remote peer or clients and supports authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes.

For more information on Phase 1 parameters in the web-based manager, see [IPsec VPN in the web-based manager on page 2035](#).

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

The following topics are included in this section:

Overview

To configure IPsec Phase 1 settings, go to **VPN > IPsec Tunnels** and edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

IPsec Phase 1 settings define:

- The remote and local ends of the IPsec tunnel
- If Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information (main mode) or in a single message with authentication information that is not encrypted (aggressive mode)
- If a preshared key or digital certificates will be used to authenticate the FortiGate unit to the VPN peer or dialup client
- If the VPN peer or dialup client is required to authenticate to the FortiGate unit. A remote peer or dialup client can authenticate by peer ID or, if the FortiGate unit authenticates by certificate, it can authenticate by peer certificate.
- The IKE negotiation proposals for encryption and authentication
- Optional XAuth authentication, which requires the remote user to enter a user name and password. A FortiGate VPN server can act as an XAuth server to authenticate dialup users. A FortiGate unit that is a dialup client can also be configured as an XAuth client to authenticate itself to the VPN server.

For all the Phase 1 web-based manager fields, see [IPsec VPN in the web-based manager on page 2035](#).

If you want to control how IKE is negotiated when there is no traffic, as well as the length of time the unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

Defining the tunnel ends

To begin defining the Phase 1 configuration, go to **VPN > IPsec Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

The remote gateway can be:

- A static IP address
- A domain name with a dynamic IP address
- A dialup client

A statically addressed remote gateway is the simplest to configure. You specify the IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer has a domain name and subscribes to a dynamic DNS service, you need to specify only the domain name. The FortiGate unit performs a DNS query to determine the appropriate IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer is a dialup client, only the dialup client can bring up the tunnel. The IP address of the client is not known until it connects to the FortiGate unit. This configuration is a typical way to provide a VPN for client PCs running VPN client software such as the FortiClient Endpoint Security application.

The local end of the VPN tunnel, the Local Interface, is the FortiGate interface that sends and receives the IPsec packets. This is usually the public interface of the FortiGate unit that is connected to the Internet (typically the WAN1 port). Packets from this interface pass to the private network through a security policy.

By default, the local VPN gateway is the IP address of the selected Local Interface. If you are configuring an interface mode VPN, you can optionally use a secondary IP address of the Local Interface as the local gateway.

Choosing Main mode or Aggressive mode

The FortiGate unit and the remote peer or dialup client exchange Phase 1 parameters in either Main mode or Aggressive mode. This choice does not apply if you use IKE version 2, which is available only for route-based configurations.

- In **Main** mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information
- In **Aggressive** mode, the Phase 1 parameters are exchanged in a single message with unencrypted authentication information.

Although Main mode is more secure, you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address, and the remote VPN peer or client is authenticated using an identifier local ID. Aggressive mode might not be as secure as Main mode, but the advantage to Aggressive mode is that it is faster than Main mode (since fewer packets are exchanged). Aggressive mode is typically used for remote access VPNs. But you would also use aggressive mode if one or both peers have dynamic external IP addresses. Descriptions of the peer options in this guide indicate whether Main or Aggressive mode is required.

Choosing the IKE version

If you create a route-based VPN, you have the option of selecting IKE version 2. Otherwise, IKE version 1 is used.

IKEv2, defined in [RFC 4306](#), simplifies the negotiation process that creates the security association (SA).

If you select IKEv2:

- There is no choice in Phase 1 of Aggressive or Main mode.
- Extended Authentication (XAUTH) is not available.
- You can select only one Diffie-Hellman Group.
- You can utilize EAP and MOBIKE.

Repeated authentication in IKEv2

This feature provides the option to control whether a device requires its peer to re-authenticate or whether re-key is sufficient. It does not influence the re-authentication or re-key behavior of the device itself, which is controlled by the peer (with the default being to re-key). This solution is in response to [RFC 4478](#). As described by the IETF, "the purpose of this is to limit the time that security associations (SAs) can be used by a third party who has gained control of the IPsec peer".

Syntax

```
config vpn ipsec phase1-interface
    edit p1
        set reauth [enable | disable]
    next
end
```

IKEv2 cookie notification for IKE_SA_INIT

IKEv2 offers an optional exchange within IKE_SA_INIT (the initial exchange between peers when establishing a secure tunnel) as a result of an inherent vulnerability in IPsec implementations, as described in [RFC 5996](#).

Two expected attacks against IKE are state and CPU exhaustion, where the target is flooded with session initiation requests from forged IP addresses. These attacks can be made less effective if a responder uses minimal CPU and commits no state to an SA until it knows the initiator can receive packets at the address from which it claims to be sending them.

If the IKE_SA_INIT response includes the cookie notification, the initiator MUST then retry the IKE_SA_INIT request, and include the cookie notification containing the received data as the first payload, and all other payloads unchanged.

Upon detecting that the number of half-open IKEv2 SAs is above the threshold value, the VPN dialup server requires all future SA_INIT requests to include a valid cookie notification payload that the server sends back, in order to preserve CPU and memory resources.

For most devices, the threshold value is set to 500, half of the maximum 1,000 connections.

This feature is enabled by default in FortiOS 5.4.

IKEv2 Quick Crash Detection

There is support for IKEv2 Quick Crash Detection (QCD) as described in [RFC 6290](#).

RFC 6290 describes a method in which an IKE peer can quickly detect that the gateway peer that it has and established an IKE session with has rebooted, crashed, or otherwise lost IKE state. When the gateway receives IKE messages or ESP packets with unknown IKE or IPsec SPIs, the IKEv2 protocol allows the gateway to send the peer an unprotected IKE message containing INVALID_IKE_SPI or INVALID_SPI notification payloads.

RFC 6290 introduces the concept of a QCD token, which is generated from the IKE SPIs and a private QCD secret, and exchanged between peers during the protected IKE AUTH exchange.

Adding Quick Crash Detection - CLI Syntax

```
config system settings
    set ike-quick-crash-detect [enable | disable]
end
```

IKEv1 Quick Crash Detection

Based on the IKEv2 QCD feature described above, IKEv1 QCD is implemented using a new IKE vendor ID, "Fortinet Quick Crash Detection", and so both endpoints must be FortiGate devices. The QCD token is sent in the Phase 1 exchange and must be encrypted, so this is only implemented for IKEv1 in Main mode (Aggressive mode is not supported as there is no available AUTH message in which to include the token).

Otherwise, the feature works the same as in IKEv2 (RFC 6290).

Authenticating the FortiGate unit

The FortiGate unit can authenticate itself to remote peers or dialup clients using either a pre-shared key or an RSA Signature (certificate).

Authenticating the FortiGate unit with digital certificates

To authenticate the FortiGate unit using digital certificates, you must have the required certificates installed on the remote peer and on the FortiGate unit. The signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer. If you use certificates to authenticate the FortiGate unit, you can also require the remote peers or dialup clients to authenticate using certificates.

Authenticating the FortiGate unit using digital certificates

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection. For interface mode, the name can be up to 15 characters long.
Remote Gateway	Select the nature of the remote connection. Each option changes the available fields you must configure. For more information, see Authenticating the FortiGate unit on page 2051 .
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 2051 . The local interface is typically the WAN1 port.
Mode	Select a mode. It is easier to use Aggressive mode. In Main mode, parameters are exchanged in multiple encrypted rounds. In Aggressive mode, parameters are exchanged in a single unencrypted message. Aggressive mode must be used when the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID). For more information, see Authenticating the FortiGate unit on page 2051 .
Authentication Method	Select Signature .

Certificate Name	<p>Select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations.</p> <p>You must obtain and load the required server certificate before this selection. If you have not loaded any certificates, use the certificate named Fortinet_Factory.</p>
Peer Options	<p>Peer options define the authentication requirements for remote peers or dialup clients. They are not for your FortiGate unit itself.</p> <p>See Authenticating the FortiGate unit on page 2051.</p>
Advanced	<p>You can use the default settings for most Phase 1 configurations. Changes are required only if your network requires them. These settings includes IKE version, DNS server, P1 proposal encryption and authentication settings, and XAuth settings. See Authenticating the FortiGate unit on page 2051.</p>

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters in the Advanced section. See [Authenticating the FortiGate unit on page 2051](#).
4. Select **OK**.

Authenticating the FortiGate unit with a pre-shared key

The simplest way to authenticate a FortiGate unit to its remote peers or dialup clients is by means of a pre-shared key. This is less secure than using certificates, especially if it is used alone, without requiring peer IDs or extended authentication (XAuth). Also, you need to have a secure way to distribute the pre-shared key to the peers.

If you use pre-shared key authentication alone, all remote peers and dialup clients must be configured with the same pre-shared key. Optionally, you can configure remote peers and dialup clients with unique pre-shared keys. On the FortiGate unit, these are configured in user accounts, not in the phase_1 settings. For more information, see [Authenticating the FortiGate unit on page 2051](#).

The pre-shared key must contain at least 6 printable characters and best practices dictate that it be known only to network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

If you authenticate the FortiGate unit using a pre-shared key, you can require remote peers or dialup clients to authenticate using peer IDs, but not client certificates.

Authenticating the FortiGate unit with a pre-shared key

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection.
Remote Gateway	Select the nature of the remote connection. For more information, see Authenticating the FortiGate unit on page 2051 .

Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 2051 . The local interface is typically the WAN1 port.
Mode	<p>Select Main or Aggressive mode.</p> <p>In Main mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</p> <p>In Aggressive mode, the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</p> <p>When the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID), you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address.</p> <p>For more information, see Authenticating the FortiGate unit on page 2051.</p>
Authentication Method	Select Pre-shared Key .
Pre-shared Key	Enter the preshared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same value at the remote peer or client. The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
Peer options	Peer options define the authentication requirements for remote peers or dialup clients, not for the FortiGate unit itself. You can require the use of peer IDs, but not client certificates. For more information, see Authenticating the FortiGate unit on page 2051 .
Advanced	You can retain the default settings unless changes are needed to meet your specific requirements. See Authenticating the FortiGate unit on page 2051 .

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters. See [Authenticating the FortiGate unit on page 2051](#).
4. Select **OK**.

Authenticating remote peers and clients

Certificates or pre-shared keys restrict who can access the VPN tunnel, but they do not identify or authenticate the remote peers or dialup clients. You have the following options for authentication:

Methods of authenticating remote VPN peers

Certificates or Pre-shared key	Local ID	User account pre-shared keys	Reference
Certificates			See Enabling VPN access for specific certificate holders on page 2054 .
Either	X		See Enabling VPN access by peer identifier on page 2056 .
Pre-shared key		X	See Enabling VPN access with user accounts and pre-shared keys on page 2057 .
Pre-shared key	X	X	See Enabling VPN access with user accounts and pre-shared keys on page 2057 .

Repeated Authentication in Internet Key Exchange (IKEv2) Protocol

This feature provides the option to control whether a device requires its peer to re-authenticate or whether re-key is sufficient. It does not influence the re-authentication or re-key behavior of the device itself, which is controlled by the peer (with the default being to re-key).

This solution is in response to [RFC 4478](#). This solution is intended to limit the time that security associations (SAs) can be used by a third party who has gained control of the IPsec peer.

CLI Syntax:

```
config vpn ipsec phase1-interface
edit p1
    set reauth [enable | disable]
next
end
```

disable: Disable IKE SA re-authentication.

enable: Enable IKE SA re-authentication.

Enabling VPN access for specific certificate holders

When a VPN peer or dialup client is configured to authenticate using digital certificates, it sends the Distinguished Name (DN) of its certificate to the FortiGate unit. This DN can be used to allow VPN access for the certificate holder. That is, a FortiGate unit can be configured to deny connections to all remote peers and dialup clients except the one having the specified DN.

Before you begin

The following procedures assume that you already have an existing Phase 1 configuration (see [Authenticating remote peers and clients on page 2053](#)). Follow the procedures below to add certificate-based authentication parameters to the existing configuration.

Before you begin, you must obtain the certificate DN of the remote peer or dialup client. If you are using the FortiClient application as a dialup client, refer to FortiClient online help for information about how to view the certificate DN. To view the certificate DN of a FortiGate unit, see [Viewing server certificate information and obtaining the local DN on page 2055](#).

Use the `config user peer` CLI command to load the DN value into the FortiGate configuration. For example, if a remote VPN peer uses server certificates issued by your own organization, you would enter information similar to the following:

```
config user peer
  edit DN_FG1000
    set cn 192.168.2.160
    set cn-type ipv4
  end
```

The value that you specify to identify the entry (for example, DN_FG1000) is displayed in the **Accept this peer certificate only** list in the IPsec Phase 1 configuration when you return to the web-based manager.

If the remote VPN peer has a CA-issued certificate to support a higher level of credibility, you would enter information similar to the following in the CLI:

```
config user peer
  edit CA_FG1000
    set ca CA_Cert_1
    set subject FG1000_at_site1
  end
```

The value that you specify to identify the entry (for example, CA_FG1000) is displayed in the Accept this peer certificate only list in the IPsec Phase 1 configuration when you return to the web-based manager. For more information about these CLI commands, see the “user” chapter of the [FortiGate CLI Reference](#).

A group of certificate holders can be created based on existing user accounts for dialup clients. To create the user accounts for dialup clients, see the “User” chapter of the [FortiGate Administration Guide](#). To create the certificate group afterward, use the `config user peergrp` CLI command. See the “user” chapter of the [FortiGate CLI Reference](#).

Viewing server certificate information and obtaining the local DN

1. Go to **System > Certificates**.
2. Note the CN value in the **Subject** field (for example, CN = 172.16.10.125, CN = info@fortinet.com, or CN = www.example.com).

Viewing CA root certificate information and obtaining the CA certificate name

1. Go to **System > Certificates > CA Certificates**.
2. Note the value in the **Name** column (for example, CA_Cert_1).

Configuring certificate authentication for a VPN

With peer certificates loaded, peer users and peer groups defined, you can configure your VPN to authenticate users by certificate.

Enabling access for a specific certificate holder or a group of certificate holders

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. From the **Authentication Method** list, select **RSA Signature**.
4. From the **Certificate Name** list, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client
5. Under **Peer Options**, select one of these options:
 - To accept a specific certificate holder, select **Accept this peer certificate only** and select the name of the certificate that belongs to the remote peer or dialup client. The certificate DN must be added to the FortiGate configuration through CLI commands before it can be selected here. See [Before you begin on page 2055](#).
 - To accept dialup clients who are members of a certificate group, select **Accept this peer certificate group only** and select the name of the group. The group must be added to the FortiGate configuration through CLI commands before it can be selected here. See [Before you begin on page 2055](#).
6. If you want the FortiGate VPN server to supply the DN of a local server certificate for authentication purposes, select **Advanced** and then from the **Local ID** list, select the DN of the certificate that the FortiGate VPN server is to use.
7. Select **OK**.

Enabling VPN access by peer identifier

Whether you use certificates or pre-shared keys to authenticate the FortiGate unit, you can require that remote peers or clients have a particular peer ID. This adds another piece of information that is required to gain access to the VPN. More than one FortiGate/FortiClient dialup client may connect through the same VPN tunnel when the dialup clients share a preshared key and assume the same identifier.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

A peer ID, also called local ID, can be up to 63 characters long containing standard regular expression characters. Local ID is set in phase1 Aggressive Mode configuration.

You cannot require a peer ID for a remote peer or client that uses a pre-shared key and has a static IP address.

Authenticating remote peers or dialup clients using one peer ID

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Aggressive** mode in any of the following cases:

- The FortiGate VPN server authenticates a FortiGate dialup client that uses a dedicated tunnel
 - A FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service
 - FortiGate/FortiClient dialup clients sharing the same preshared key and local ID connect through the same VPN tunnel
4. For the **Peer Options**, select **This peer ID** and type the identifier into the corresponding field.
 5. Select **OK**.

Assigning an identifier (local ID) to a FortiGate unit

Use this procedure to assign a peer ID to a FortiGate unit that acts as a remote peer or dialup client.

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Advanced**.
4. In the **Local ID** field, type the identifier that the FortiGate unit will use to identify itself.
5. Set **Mode** to **Aggressive** if any of the following conditions apply:
 - The FortiGate unit is a dialup client that will use a unique ID to connect to a FortiGate dialup server through a dedicated tunnel.
 - The FortiGate unit has a dynamic IP address, subscribes to a dynamic DNS service, and will use a unique ID to connect to the remote VPN peer through a dedicated tunnel.
 - The FortiGate unit is a dialup client that shares the specified ID with multiple dialup clients to connect to a FortiGate dialup server through the same tunnel.
6. Select **OK**.

Configuring the FortiClient application

Follow this procedure to add a peer ID to an existing FortiClient configuration:

1. Start the FortiClient application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit > Advanced**.
4. Under **Policy**, select **Config**.
5. In the **Local ID** field, type the identifier that will be shared by all dialup clients. This value must match the **This peer ID** value that you specified previously in the Phase 1 gateway configuration on the FortiGate unit.
6. Select **OK** to close all dialog boxes.
7. Configure all dialup clients the same way using the same preshared key and local ID.

Enabling VPN access with user accounts and pre-shared keys

You can permit access only to remote peers or dialup clients that have pre-shared keys and/or peer IDs configured in user accounts on the FortiGate unit.

If you want two VPN peers (or a FortiGate unit and a dialup client) to accept reciprocal connections based on peer IDs, you must enable the exchange of their identifiers when you define the Phase 1 parameters.

The following procedures assume that you already have an existing Phase 1 configuration (see [Authenticating remote peers and clients on page 2053](#)). Follow the procedures below to add ID checking to the existing configuration.

Before you begin, you must obtain the identifier (local ID) of the remote peer or dialup client. If you are using the FortiClient Endpoint Security application as a dialup client, refer to the Authenticating FortiClient Dialup Clients Technical Note to view or assign an identifier. To assign an identifier to a FortiGate dialup client or a FortiGate unit that has a dynamic IP address and subscribes to a dynamic DNS service, see [Assigning an identifier \(local ID\) to a FortiGate unit on page 2057](#).

If required, a dialup user group can be created from existing user accounts for dialup clients. To create the user accounts and user groups, see the [User Authentication](#) handbook chapter.

The following procedure supports FortiGate/FortiClient dialup clients that use unique preshared keys and/or peer IDs. The client must have an account on the FortiGate unit and be a member of the dialup user group.

The dialup user group must be added to the FortiGate configuration before it can be selected. For more information, see the [User Authentication](#) handbook chapter.

The FortiGate dialup server compares the local ID that you specify at each dialup client to the FortiGate user-account user name. The dialup-client preshared key is compared to a FortiGate user-account password.

Authenticating dialup clients using unique preshared keys and/or peer IDs

1. At the FortiGate VPN server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. If the clients have unique peer IDs, set **Mode** to **Aggressive**.
4. Clear the **Pre-shared Key** field.
The user account password will be used as the preshared key.
5. Select **Peer ID from dialup group** and then select the group name from the list of user groups.
6. Select **OK**.

Follow this procedure to add a unique pre-shared key and unique peer ID to an existing FortiClient configuration.

Configuring FortiClient - pre-shared key and peer ID

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit**.
4. In the **Preshared Key** field, type the FortiGate password that belongs to the dialup client (for example, 1234546).
The user account password will be used as the preshared key.
5. Select **Advanced**.
6. Under **Policy**, select **Config**.
7. In the **Local ID** field, type the FortiGate user name that you assigned previously to the dialup client (for example, FortiClient1).
8. Select **OK** to close all dialog boxes.

Configure all FortiClient dialup clients this way using unique preshared keys and local IDs.

Follow this procedure to add a unique pre-shared key to an existing FortiClient configuration.

Configuring FortiClient - preshared key only

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration

3. Select **Advanced > Edit**.
4. In the **Preshared Key** field, type the user name, followed by a "+" sign, followed by the password that you specified previously in the user account settings on the FortiGate unit (for example, FC2+1FG6LK).
5. Select **OK** to close all dialog boxes.

Configure all the FortiClient dialup clients this way using their unique peer ID and pre-shared key values.

Defining IKE negotiation parameters

In Phase 1, the two peers exchange keys to establish a secure communication channel between them. As part of the Phase 1 process, the two peers authenticate each other and negotiate a way to encrypt further communications for the duration of the session. For more information see [Defining IKE negotiation parameters on page 2059](#). The Phase 1 Proposal parameters select the encryption and authentication algorithms that are used to generate keys for protecting negotiations.

The IKE negotiation parameters determine:

- Which encryption algorithms may be applied for converting messages into a form that only the intended recipient can read
- Which authentication hash may be used for creating a keyed hash from a preshared or private key
- Which Diffie-Hellman group (DH Group) will be used to generate a secret session key

Phase 1 negotiations (in main mode or aggressive mode) begin as soon as a remote VPN peer or client attempts to establish a connection with the FortiGate unit. Initially, the remote peer or dialup client sends the FortiGate unit a list of potential cryptographic parameters along with a session ID. The FortiGate unit compares those parameters to its own list of advanced Phase 1 parameters and responds with its choice of matching parameters to use for authenticating and encrypting packets. The two peers handle the exchange of encryption keys between them, and authenticate the exchange through a preshared key or a digital signature.

Generating keys to authenticate an exchange

The FortiGate unit supports the generation of secret session keys automatically using a Diffie-Hellman algorithm. These algorithms are defined in [RFC 2409](#). The **Keylife** setting in the **Phase 1 Proposal** area determines the amount of time before the Phase 1 key expires. Phase 1 negotiations are re-keyed automatically when there is an active security association. See [Dead Peer Detection on page 2062](#).

You can enable or disable automatic re-keying between IKE peers through the `phase1-rekey` attribute of the `config system global` CLI command. For more information, see the "System" chapter of the [FortiGate CLI Reference](#).

When in FIPS-CC mode, the FortiGate unit requires DH key exchange to use values at least 3072 bits long. However most browsers need the key size set to 1024. You can set the minimum size of the DH keys in the CLI.

```
config system global
    set dh-params 3072
end
```

When you use a preshared key (shared secret) to set up two-party authentication, the remote VPN peer or client and the FortiGate unit must both be configured with the same preshared key. Each party uses a session key derived from the Diffie-Hellman exchange to create an authentication key, which is used to sign a known combination of inputs using an authentication algorithm (such as HMAC-MD5, HMAC-SHA-1, or HMAC-SHA-

256). Hash-based Message Authentication Code (HMAC) is a method for calculating an authentication code using a hash function plus a secret key, and is defined in [RFC 2104](#). Each party signs a different combination of inputs and the other party verifies that the same result can be computed.

For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the [Hardware Acceleration](#) handbook chapter.

When you use preshared keys to authenticate VPN peers or clients, you must distribute matching information to all VPN peers and/or clients whenever the preshared key changes.

As an alternative, the remote peer or dialup client and FortiGate unit can exchange digital signatures to validate each other's identity with respect to their public keys. In this case, the required digital certificates must be installed on the remote peer and on the FortiGate unit. By exchanging certificate DNs, the signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer.

The following procedure assumes that you already have a Phase 1 definition that describes how remote VPN peers and clients will be authenticated when they attempt to connect to a local FortiGate unit. For information about the Local ID and XAuth options, see [Defining IKE negotiation parameters on page 2059](#) and [Defining IKE negotiation parameters on page 2059](#). Follow this procedure to add IKE negotiation parameters to the existing definition.

Defining IKE negotiation parameters

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Phase 1 Proposal** and include the appropriate entries as follows:

Phase 1 Proposal	<p>Select the encryption and authentication algorithms that will be used to generate keys for protecting negotiations.</p> <p>Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.</p> <p>It is invalid to set both Encryption and Authentication to null.</p>
Encryption	<p>Select a symmetric-key algorithms:</p> <p>NULL — Do not use an encryption algorithm.</p> <p>DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</p> <p>3DES — Triple-DES; plain text is encrypted three times by three keys.</p> <p>AES128 — A 128-bit block algorithm that uses a 128-bit key.</p> <p>AES192 — A 128-bit block algorithm that uses a 192-bit key.</p> <p>AES256 — A 128-bit block algorithm that uses a 256-bit key.</p>

Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest. MD5 — Message Digest 5. SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p> <p>For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.</p>
Diffie-Hellman Group	<p>Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, 14 through 21, and 27 through 30. When using aggressive mode, DH groups cannot be negotiated. By default, DH group 14 is selected, to provide sufficient protection for stronger cipher suites that include AES and SHA2. If you select multiple DH groups, the order they appear in the configuration is the order in which they are negotiates.</p> <p>If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client.</p> <p>When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit.</p> <p>If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.</p>
Keylife	<p>Type the amount of time (in seconds) that will be allowed to pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172800 seconds.</p>
Nat-traversal	<p>Enable this option if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared). When in doubt, enable NAT-traversal. See NAT traversal on page 2062.</p>

Keepalive Frequency	If you enabled NAT traversal, enter a keepalive frequency setting. The value represents an interval from 0 to 900 seconds where the connection will be maintained with no activity. For additional security this value must be as low as possible. See NAT keepalive frequency on page 2062 .
Dead Peer Detection	Enable this option to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. This feature minimizes the traffic required to check if a VPN peer is available or unavailable (dead). See Dead Peer Detection on page 2062 .

NAT traversal

Network Address Translation (NAT) is a way to convert private IP addresses to publicly routable Internet addresses and vice versa. When an IP packet passes through a NAT device, the source or destination address in the IP header is modified. FortiGate units support NAT version 1 (encapsulate on port 500 with non-IKE marker), version 3 (encapsulate on port 4500 with non-ESP marker), and compatible versions.

NAT cannot be performed on IPsec packets in ESP tunnel mode because the packets do not contain a port number. As a result, the packets cannot be demultiplexed. To work around this, the FortiGate unit provides a way to protect IPsec packet headers from NAT modifications. When the Nat-traversal option is enabled, outbound encrypted packets are wrapped inside a UDP IP header that contains a port number. This extra encapsulation allows NAT devices to change the port number without modifying the IPsec packet directly.

To provide the extra layer of encapsulation on IPsec packets, the Nat-traversal option must be enabled whenever a NAT device exists between two FortiGate VPN peers or a FortiGate unit and a dialup client such as FortiClient. On the receiving end, the FortiGate unit or FortiClient removes the extra layer of encapsulation before decrypting the packet.

Additionally, you can force IPsec to use NAT traversal. If NAT is set to **Forced**, the FortiGate will use a port value of zero when constructing the NAT discovery hash for the peer. This causes the peer to think it is behind a NAT device, and it will use UDP encapsulation for IPsec, even if no NAT is present. This approach maintains interoperability with any IPsec implementation that supports the NAT-T RFC.

NAT keepalive frequency

When a NAT device performs network address translation on a flow of packets, the NAT device determines how long the new address will remain valid if the flow of traffic stops (for example, the connected VPN peer may be idle). The device may reclaim and reuse a NAT address when a connection remains idle for too long.

To work around this, when you enable NAT traversal specify how often the FortiGate unit sends periodic keepalive packets through the NAT device in order to ensure that the NAT address mapping does not change during the lifetime of a session. To be effective, the keepalive interval must be smaller than the session lifetime value used by the NAT device.

The keepalive packet is a 138-byte ISAKMP exchange.

Dead Peer Detection

Sometimes, due to routing issues or other difficulties, the communication link between a FortiGate unit and a VPN peer or client may go down. Packets could be lost if the connection is left to time out on its own. The FortiGate unit provides a mechanism called Dead Peer Detection (DPD), sometimes referred to as gateway detection or ping server, to prevent this situation and reestablish IKE negotiations automatically before a

connection times out: the active Phase 1 security associations are caught and renegotiated (rekeyed) before the Phase 1 encryption key expires.

By default, Dead Peer Detection sends probe messages every five seconds by default (see `dpd-retryinterval` in the [FortiGate CLI Reference](#)). If you are experiencing high network traffic, you can experiment with increasing the ping interval. However longer intervals will require more traffic to detect dead peers which will result in more traffic.

In the web-based manager, the Dead Peer Detection option can be enabled when you define advanced Phase 1 options. The `config vpn ipsec phase1` CLI command supports additional options for specifying a retry count and a retry interval.

For more information about these commands and the related `config router gwdetect` CLI command, see the [FortiGate CLI Reference](#).

For example, enter the following CLI commands to configure dead peer detection on the existing IPsec Phase 1 configuration called `test` to use 15 second intervals and to wait for 3 missed attempts before declaring the peer dead and taking action.

```
config vpn ipsec phase1-interface
  edit <value>
    set dpd [disable | on-idle | on-demand]
    set dpd-retryinterval 15
    set dpd-retrycount 3
  next
end
```

DPD Scalability

On a dial-up server, if a multitude of VPN connections are idle, the increased DPD exchange could negatively impact the performance/load of the daemon. For this reason, an option is available in the CLI to send DPD passively in a mode called "on-demand".

- When there is no traffic and the last DPD-ACK had been received, IKE will not send DPDs periodically.
 - IKE will only send out DPDs if there are outgoing packets to send but no inbound packets had since been received.
-

Syntax

Set DPD to `on-demand` to trigger DPD when IPsec traffic is sent but no reply is received from the peer.

```
config vpn ipsec phase1-interface
  edit <value>
    set dpd [disable | on-idle | on-demand]
  next
end
```

Certificate key size control

Proxy will choose the same SSL key size as the HTTPS server. If the key size from the server is 512, the proxy will choose 1024. If the key size is bigger than 1024, the proxy will choose 2048.

As a result, the `firewall ssl-ssh-profile` commands `certname-rsa`, `certname-dsa`, and `certname-ecdsa` have been replaced with more specific key size control commands under `vpn certificate` setting.

CLI syntax

```
config vpn certificate setting
  set certname-rsa1024 <name>
  set certname-rsa2048 <name>
  set certname-dsa1024 <name>
  set certname-dsa2048 <name>
  set certname-ecdsa256 <name>
  set certname-ecdsa384 <name>
end
```

Using XAuth authentication

Extended authentication (XAuth) increases security by requiring the remote dialup client user to authenticate in a separate exchange at the end of Phase 1. XAuth draws on existing FortiGate user group definitions and uses established authentication mechanisms such as PAP, CHAP, RADIUS, and LDAP to authenticate dialup clients. You can configure a FortiGate unit to function either as an XAuth server or an XAuth client. If the server or client is attempting a connection using XAuth and the other end is not using XAuth, the failed connection attempts that are logged will not specify XAuth as the reason.

Using the FortiGate unit as an XAuth server

A FortiGate unit can act as an XAuth server for dialup clients. When the Phase 1 negotiation completes, the FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

If the user records on the RADIUS server have suitably configured Framed-IP-Address fields, you can assign client virtual IP addresses by XAuth instead of from a DHCP address range. See [Assigning VIPs by RADIUS user group on page 1](#).

The authentication protocol to use for XAuth depends on the capabilities of the authentication server and the XAuth client:

- Select **PAP Server** whenever possible.
- You must select **PAP Server** for all implementations of LDAP and some implementations of Microsoft RADIUS.
- Select **Auto Server** when the authentication server supports **CHAP Server** but the XAuth client does not. The FortiGate unit will use PAP to communicate with the XAuth client and CHAP to communicate with the authentication server. You can also use **Auto Server** to allow multiple source interfaces to be defined in an IPsec/IKE policy

Before you begin, create user accounts and user groups to identify the dialup clients that need to access the network behind the FortiGate dialup server. If password protection will be provided through an external RADIUS or LDAP server, you must configure the FortiGate dialup server to forward authentication requests to the authentication server.

Authenticating a dialup user group using XAuth settings

1. At the FortiGate dialup server, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Select **Convert To Custom Tunnel**.

3. Edit **XAUTH**, select the **Type** setting, which determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
 - **Disabled** — Disables XAuth settings.
 - **PAP Server** — Password Authentication Protocol.
 - **CHAP Server** — Challenge-Handshake Authentication Protocol.
 - **Auto Server** — Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server.
4. From the **User Group** list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here. For multiple user groups to be defined in the IPsec/IKE policy, select **Inherit from policy**.
4. Select **OK**.
5. Create as many policies as needed, specifying **Source User(s)** and **Destination Address**. For example, one policy could have **user1** have access to **test_local_subnet_1**, while **user2** has access to **test_local_subnet_2**.

As of FortiOS 5.4.1, when XAuth settings are enabled, **Inherit from policy** is only available under **PAP Server** and **CHAP Server**, not **Auto Server**. Because of this, only one user group may be defined for **Auto Server**.

Using the FortiGate unit as an XAuth client

If the FortiGate unit acts as a dialup client, the remote peer, acting as an XAuth server, might require a username and password. You can configure the FortiGate unit as an XAuth client, with its own username and password, which it provides when challenged.

Configuring the FortiGate dialup client as an XAuth client

1. At the FortiGate dialup client, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Under **XAuth**, select **Enable as Client**.
4. In the **Username** field, type the FortiGate PAP, CHAP, RADIUS, or LDAP user name that the FortiGate XAuth server will compare to its records when the FortiGate XAuth client attempts to connect.
5. In the **Password** field, type the password to associate with the user name.
6. Select **OK**.

Dynamic IPsec route control

You can add a route to a peer destination selector by using the `add-route` option, which is available for all dynamic IPsec Phases 1 and 2, for both policy-based and route-based IPsec VPNs. This option was previously only available when `mode-cfg` was enabled in Phase 1.

The `add-route` option adds a route to the FortiGate unit's routing information base when the dynamic tunnel is negotiated. You can use the `distance` and `priority` options to set the distance and priority of this route. If this results in a route with the lowest distance, it is added to the FortiGate unit's forwarding information base.

You can also enable add-route in any policy-based or route-based Phase 2 configuration that is associated with a dynamic (dialup) Phase 1. In Phase 2, add-route can be enabled, disabled, or set to use the same route as Phase 1.

The add-route feature is enabled by default and is configured in the CLI.

Syntax

Phase 1

```
config vpn ipsec
  edit <name>
    set type dynamic
    set add-route {enable | disable}
  end
end
```

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
  edit <name>
    set add-route {phase1 | enable | disable}
  end
end
```

Blocking IPsec SA Negotiation

For interface-based IPsec, IPsec SA negotiation blocking can only be removed if the peer offers a wildcard selector. If a wildcard selector is offered then the wildcard route will be added to the routing table with the distance/priority value configured in Phase 1 and, if that is the route with the lowest distance, it is installed into the forwarding information base.

In cases where this occurs, it is important to ensure that the distance value configured on Phase 1 is set appropriately.

Phase 2 parameters

This section describes the Phase 2 parameters that are required to establish communication through a VPN.

The following topics are included in this section:

Phase 2 settings

After IPsec VPN Phase 1 negotiations complete successfully, Phase 2 negotiation begins. Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

When defining Phase 2 parameters, you can choose any set of Phase 1 parameters to set up a secure connection and authenticate the remote peer.

For more information on Phase 2 settings in the web-based manager, see [IPsec VPN in the web-based manager on page 2035](#).

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

Phase 2 Proposals

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). The keys are generated automatically using a Diffie-Hellman algorithm.

Replay Detection

IPsec tunnels can be vulnerable to replay attacks. Replay Detection enables the FortiGate unit to check all IPsec packets to see if they have been received before. If any encrypted packets arrive out of order, the FortiGate unit discards them.

IKE/IPsec Extended Sequence Number (ESN) support

64-bit Extended Sequence numbers (as described in RFC 4303, RFC 4304 as an addition to IKEv1, and RFC 5996 for IKEv2.) are supported for IPsec when Replay Detection is enabled.

Perfect Forward Secrecy (PFS)

By default, Phase 2 keys are derived from the session key created in Phase 1. Perfect Forward Secrecy (PFS) forces a new Diffie-Hellman exchange when the tunnel starts and whenever the Phase 2 keylife expires, causing a new key to be generated each time. This exchange ensures that the keys created in Phase 2 are unrelated to the Phase 1 keys or any other keys generated automatically in Phase 2.

Keylife

The Keylife setting sets a limit on the length of time that a Phase 2 key can be used. The default units are seconds. Alternatively, you can set a limit on the number of kilobytes (KB) of processed data, or both. If you select

both, the key expires when either the time has passed or the number of KB have been processed. When the Phase 2 key expires, a new key is generated without interrupting service.

Quick mode selectors

Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure.

The default settings are as broad as possible: any IP address or configured address object, using any protocol, on any port.

While the drop down menus for specifying an address also show address groups, the use of address groups may not be supported on a remote endpoint device that is not a FortiGate.

The address groups are at the bottom of the list to make it easy to distinguish between addresses and address groups.

When configuring Quick Mode selector **Source address** and **Destination address**, valid options include IPv4 and IPv6 single addresses, IPv4 subnet, or IPv6 subnet. For more information on IPv6 IPsec VPN, see [Overview of IPv6 IPsec support on page 1](#).

There are some configurations that require specific selectors:

- The VPN peer is a third-party device that uses specific phase2 selectors.
- The FortiGate unit connects as a dialup client to another FortiGate unit, in which case (usually) you must specify a source IP address, IP address range, or subnet. However, this is not required if you are using dynamic routing and mode-cfg.

With FortiOS VPNs, your network has multiple layers of security, with quick mode selectors being an important line of defence.

- Routes guide traffic from one IP address to another.
- Phase 1 and Phase 2 connection settings ensure there is a valid remote end point for the VPN tunnel that agrees on the encryption and parameters.
- Quick mode selectors allow IKE negotiations only for allowed peers.
- Security policies control which IP addresses can connect to the VPN.
- Security policies also control what protocols are allowed over the VPN along with any bandwidth limiting.

FortiOS is limited with IKEv2 selector matching. When using IKEv2 with a named traffic selector, no more than 32 subnets per traffic selector are added, since FortiOS doesn't fully implement the IKEv2 selector matching rules.

The workaround is to use multiple Phase 2s. If the configuration is FGT <-> FGT, then the better alternative is to just use 0.0.0.0 <-> 0.0.0.0 and use the firewall policy for enforcement.

Using the add-route option

Consider using the `add-route` option to add a route to a peer destination selector. Phase 2 includes the option of allowing the `add-route` to automatically match the settings in Phase 1. For more information, refer to [Phase 1 parameters on page 2048](#).

Syntax

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
  edit <name>
    set add-route {phase1 | enable | disable}
  end
end
```

Configuring the Phase 2 parameters

If you are creating a hub-and-spoke configuration or an Internet-browsing configuration, you may have already started defining some of the required Phase 2 parameters. If so, edit the existing definition to complete the configuration.

Specifying the Phase 2 parameters

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter a **Name** for the Phase 2 configuration, and select a **Phase 1** configuration from the drop-down list.
4. Select **Advanced**.
5. Include the appropriate entries as follows:

Phase 2 Proposal

Select the encryption and authentication algorithms that will be used to change data into encrypted code.

Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.

It is invalid to set both **Encryption** and **Authentication** to null.

Encryption

Select a symmetric-key algorithms:

NULL — Do not use an encryption algorithm.

DES — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.

3DES — Triple-DES; plain text is encrypted three times by three keys.

AES128 — A 128-bit block algorithm that uses a 128-bit key.

AES192 — A 128-bit block algorithm that uses a 192-bit key.

AES256 — A 128-bit block algorithm that uses a 256-bit key.

Authentication	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <p>NULL — Do not use a message digest. MD5 — Message Digest 5. SHA1 — Secure Hash Algorithm 1 - a 160-bit message digest.</p> <p>To specify one combination only, set the Encryption and Authentication options of the second combination to NULL. To specify a third combination, use the Add button beside the fields for the second combination.</p> <p>For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.</p>
Enable replay detection	Optionally enable or disable replay detection. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Enable or disable PFS. Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
Diffie-Hellman Group	Select one Diffie-Hellman group (1, 2, 5, 14 through 21, or 27 through 30). The remote peer or dialup client must be configured to use the same group.
Keylife	Select the method for determining when the Phase 2 key expires: Seconds , KBytes , or Both . If you select Both , the key expires when either the time has passed or the number of KB have been processed. The range is from 120 to 172800 seconds, or from 5120 to 2147483648 KB.
Autokey Keep Alive	Enable the option if you want the tunnel to remain active when no data is being processed.
Auto-negotiate	Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.
DHCP-IPsec	<p>Select Enable if the FortiGate unit acts as a dialup server and FortiGate DHCP server or relay will be used to assign VIP addresses to FortiClient dialup clients. The DHCP server or relay parameters must be configured separately.</p> <p>If the FortiGate unit acts as a dialup server and the FortiClient dialup client VIP addresses match the network behind the dialup server, select Enable to cause the FortiGate unit to act as a proxy for the dialup clients.</p> <p>This is available only for Phase 2 configurations associated with a dialup Phase 1 configuration. It works only on policy-based VPNs.</p>

Autokey Keep Alive

The Phase 2 SA has a fixed duration. If there is traffic on the VPN as the SA nears expiry, a new SA is negotiated and the VPN switches to the new SA without interruption. If there is no traffic, however, the SA expires (by default) and the VPN tunnel goes down. A new SA will not be generated until there is traffic.

The Autokey Keep Alive option ensures that a new Phase 2 SA is negotiated, even if there is no traffic, so that the VPN tunnel stays up.

Auto-negotiate

By default, the Phase 2 security association (SA) is not negotiated until a peer attempts to send data. The triggering packet and some subsequent packets are dropped until the SA is established. Applications normally resend this data, so there is no loss, but there might be a noticeable delay in response to the user.

If the tunnel goes down, the auto-negotiate feature (when enabled) attempts to re-establish the tunnel. Auto-negotiate initiates the Phase 2 SA negotiation automatically, repeating every five seconds until the SA is established.

Automatically establishing the SA can be important for a dialup peer. It ensures that the VPN tunnel is available for peers at the server end to initiate traffic to the dialup peer. Otherwise, the VPN tunnel does not exist until the dialup peer initiates traffic.

The auto-negotiate feature is available through the Command Line Interface (CLI) via the following commands:

```
config vpn ipsec phase2
  edit <phase2_name>
    set auto-negotiate enable
  end
```

Installing dynamic selectors via auto-negotiate

The IPsec SA connect message generated is used to install dynamic selectors. These selectors can now be installed via the auto-negotiate mechanism. When phase 2 has auto-negotiate enabled, and phase 1 has mesh-selector-type set to **subnet**, a new dynamic selector will be installed for each combination of source and destination subnets. Each dynamic selector will inherit the auto-negotiate option from the template selector and begin SA negotiation. Phase 2 selector sources from dial-up clients will all establish SAs without traffic being initiated from the client subnets to the hub.

DHCP-IPsec

Select this option if the FortiGate unit assigns VIP addresses to FortiClient dialup clients through a DHCP server or relay. This option is available only if the Remote Gateway in the Phase 1 configuration is set to Dialup User and it works only on policy-based VPNs.

With the DHCP-IPsec option, the FortiGate dialup server acts as a proxy for FortiClient dialup clients that have VIP addresses on the subnet of the private network behind the FortiGate unit. In this case, the FortiGate dialup server acts as a proxy on the local private network for the FortiClient dialup client. When a host on the network behind the dialup server issues an ARP request that corresponds to the device MAC address of the FortiClient host (when a remote server sends an ARP to the local FortiClient dialup client), the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel.

This feature prevents the VIP address assigned to the FortiClient dialup client from causing possible arp broadcast problems — the normal and VIP addresses can confuse some network switches by two addresses having the same MAC address.

Defining VPN security policies

This section explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN, and how to define appropriate security policies.

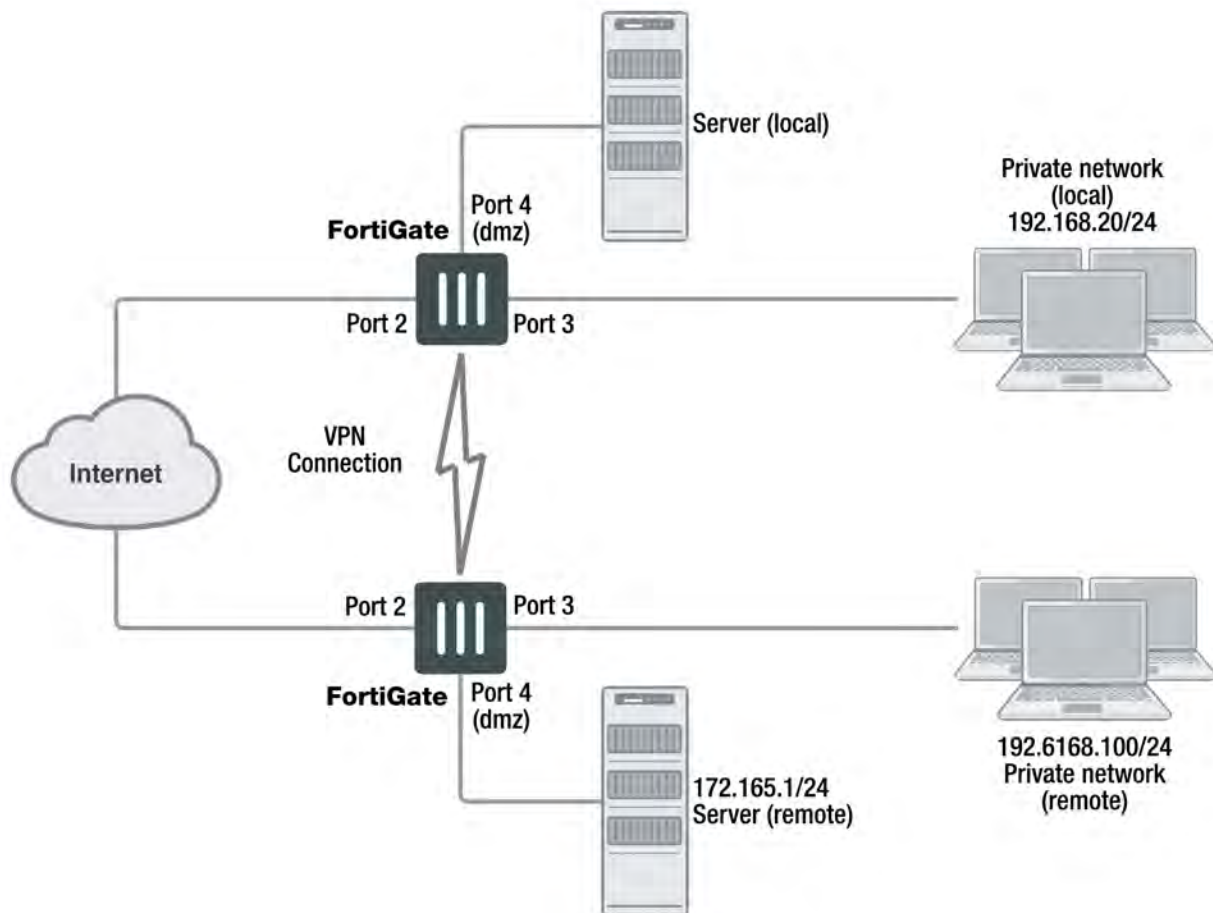

The following topics are included in this section:

Defining policy addresses

A VPN tunnel has two end points. These end points may be VPN peers such as two FortiGate gateways. Encrypted packets are transmitted between the end points. At each end of the VPN tunnel, a VPN peer intercepts encrypted packets, decrypts the packets, and forwards the decrypted IP packets to the intended destination.

You need to define firewall addresses for the private networks behind each peer. You will use these addresses as the source or destination address depending on the security policy.

Example topology for the following policies

In general:

- In a gateway-to-gateway, hub-and-spoke, dynamic DNS, redundant-tunnel, or transparent configuration, you need to define a policy address for the private IP address of the network behind the remote VPN peer (for example, 192.168.10.0/255.255.255.0 or 192.168.10.0/24).
- In a peer-to-peer configuration, you need to define a policy address for the private IP address of a server or host behind the remote VPN peer (for example, 172.16.5.1/255.255.255.255 or 172.16.5.1/32 or 172.16.5.1).

For a FortiGate dialup server in a dialup-client or Internet-browsing configuration:

- If you are not using VIP addresses, or if the FortiGate dialup server assigns VIP addresses to FortiClient dialup clients through FortiGate DHCP relay, select the predefined destination address “all” in the security policy to refer to the dialup clients.
- If you assign VIP addresses to FortiClient dialup clients manually, you need to define a policy address for the VIP address assigned to the dialup client (for example, 10.254.254.1/32), or a subnet address from which the VIP addresses are assigned (for example, 10.254.254.0/24 or 10.254.254.0/255.255.255.0).
- For a FortiGate dialup client in a dialup-client or Internet-browsing configuration, you need to define a policy address for the private IP address of a host, server, or network behind the FortiGate dialup server.

Defining a security IP address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. In the **Name** field, type a descriptive name that represents the network, server(s), or host(s).
3. In **Type**, select **Subnet**.
4. In the **Subnet/IP Range** field, type the corresponding IP address and subnet mask.
For a subnet you could use the format 172.16.5.0/24 or its equivalent 172.16.5.0/255.255.255.0. For a server or host it would likely be 172.16.5.1/32. Alternately you can use an IP address range such as 192.168.10.[80-100] or 192.168.10.80-192.168.10.100.
5. Select **OK**.

Defining security policies for policy-based and route-based VPNs

Security policies allow IP traffic to pass between interfaces on a FortiGate unit. You can limit communication to particular traffic by specifying source address and destination addresses. Then only traffic from those addresses will be allowed.

Policy-based and route-based VPNs require different security policies.

- A policy-based VPN requires an IPsec security policy. You specify the interface to the private network, the interface to the remote peer and the VPN tunnel. A single policy can enable traffic inbound, outbound, or in both directions.
- A route-based VPN requires an Accept security policy for each direction. As source and destination interfaces, you specify the interface to the private network and the virtual IPsec interface (Phase 1 configuration) of the VPN. The IPsec interface is the destination interface for the outbound policy and the source interface for the inbound policy. One security policy must be configured for each direction of each VPN interface.

There are examples of security policies for both policy-based and route-based VPNs throughout this guide. See [Route-based or policy-based VPN on page 2113](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Policy-based VPN

An IPsec security policy enables the transmission and reception of encrypted packets, specifies the permitted direction of VPN traffic, and selects the VPN tunnel. In most cases, a single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel. Be aware of the following considerations below before creating an IPsec security policy.

Allow traffic to be initiated from the remote site

Security policies specify which IP addresses can initiate a tunnel. By default, traffic from the local private network initiates the tunnel. When the **Allow traffic to be initiated from the remote site** option is selected, traffic from a dialup client, or a computer on a remote network, initiates the tunnel. Both can be enabled at the same time for bi-directional initiation of the tunnel.

Outbound and inbound NAT

When a FortiGate unit operates in NAT mode, you can also enable inbound or outbound NAT. Outbound NAT may be performed on outbound encrypted packets or IP packets in order to change their source address before they are sent through the tunnel. Inbound NAT is performed to intercept and decrypt emerging IP packets from the tunnel.

By default, these options are not selected in security policies and can only be set through the CLI. For more information on this, see the “config firewall” chapter of the [FortiGate CLI Reference](#).

Source and destination addresses
