Most security policies control outbound IP traffic. A VPN outbound policy usually has a source address originating on the private network behind the local FortiGate unit, and a destination address belonging to a dialup VPN client or a network behind the remote VPN peer. The source address that you choose for the security policy identifies from where outbound cleartext IP packets may originate, and also defines the local IP address or addresses that a remote server or client will be allowed to access through the VPN tunnel. The destination address that you choose identifies where IP packets must be forwarded after they are decrypted at the far end of the tunnel, and determines the IP address or addresses that the local network will be able to access at the far end of the tunnel.

Enabling other policy features

You can fine-tune a policy for services such as HTTP, FTP, and POP3, enable logging, traffic shaping, antivirus protection, web filtering, email filtering, file transfer, email services, and optionally allow connections according to a predefined schedule.

As an option, differentiated services (diffserv or DSCP) for the security policy can be enabled through the CLI. For more information on this feature, see the [Traffic Shaping](#) handbook chapter, or the “firewall” chapter of the FortiGate CLI Reference.

Before you begin

Before you define the IPsec policy, you must:

- Define the IP source and destination addresses. See [Defining policy addresses on page 2073](#).
- Specify the Phase 1 authentication parameters. See [Phase 1 parameters on page 2048](#).
- Specify the Phase 2 parameters. See [Phase 2 parameters on page 2067](#).

Defining an IPsec security policy

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** and set the following options:

Name	Enter a name for the security policy.
Incoming Interface	Select the local interface to the internal (private) network.
Outgoing Interface	Select the local interface to the external (public) network.
Source	Select the name that corresponds to the local network, server(s), or host(s) from which IP packets may originate.
Destination Address	Select the name that corresponds to the remote network, server(s), or host(s) to which IP packets may be delivered.
Schedule	Keep the default setting (always) unless changes are needed to meet specific requirements.
Service	Keep the default setting (ALL) unless changes are needed to meet your specific requirements.
Action	For the purpose of this configuration, set Action to IPsec . Doing this will close Firewall / Network Options and open VPN Tunnel options. Select the VPN tunnel of your choice, and select Allow traffic to be initiated from the remote site , which will allow traffic from the remote network to initiate the tunnel.

3. You may enable UTM features, and/or event logging, or select advanced settings to authenticate a user group, or shape traffic. For more information, see the [Firewall](#) handbook chapter.
4. Select **OK**.
5. Place the policy in the policy list above any other policies having similar source and destination addresses.

Defining multiple IPsec policies for the same tunnel

You must define at least one IPsec policy for each VPN tunnel. If the same remote server or client requires access to more than one network behind a local FortiGate unit, the FortiGate unit must be configured with an IPsec policy for each network. Multiple policies may be required to configure redundant connections to a remote destination or control access to different services at different times.

To ensure a secure connection, the FortiGate unit must evaluate policies with **Action** set to **IPsec** before **ACCEPT** and **DENY**. Because the FortiGate unit reads policies starting at the top of the list, you must move all IPsec policies to the top of the list, and be sure to reorder your multiple IPsec policies that apply to the tunnel so that specific constraints can be evaluated before general constraints.

Adding multiple IPsec policies for the same VPN tunnel can cause conflicts if the policies specify similar source and destination addresses, but have different settings for the same service. When policies overlap in this manner, the system may apply the wrong IPsec policy or the tunnel may fail.

For example, if you create two equivalent IPsec policies for two different tunnels, it does not matter which one comes first in the list of IPsec policies — the system will select the correct policy based on the specified source and destination addresses. If you create two different IPsec policies for the same tunnel (that is, the two policies treat traffic differently depending on the nature of the connection request), you might have to reorder the IPsec policies to ensure that the system selects the correct IPsec policy.

Route-based VPN

When you define a route-based VPN, you create a virtual IPsec interface on the physical interface that connects to the remote peer. You create ordinary Accept security policies to enable traffic between the IPsec interface and the interface that connects to the private network. This makes configuration simpler than for policy-based VPNs, which require IPsec security policies.

Defining security policies for a route-based VPN

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** and define an **ACCEPT** security policy to permit communication between the local private network and the private network behind the remote peer. Enter these settings in particular:

Name	Enter a name for the security policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the IPsec Interface you configured.
Source	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind the remote peer.
Action	Select ACCEPT .
NAT	Disable NAT .

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

3. Select **Create New** and enter these settings in particular:

Name	Enter a name for the security policy.
Incoming Interface	Select the IPsec Interface you configured.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select the address name that you defined for the private network behind the remote peer.

Destination Address	Select the address name that you defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .

Gateway-to-gateway

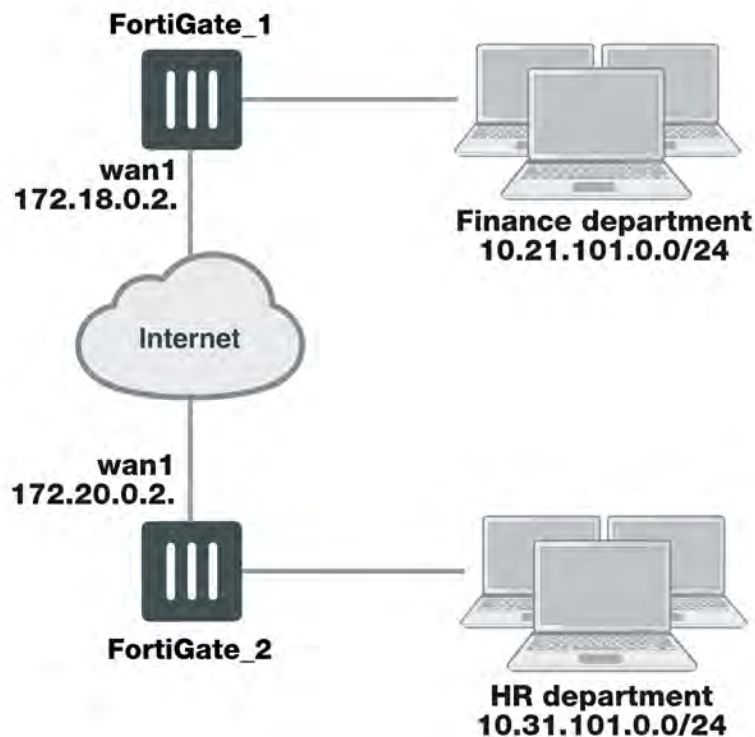

This section explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN.

The following topics are included in this section:

Configuration overview

In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Example gateway-to-gateway configuration

In some cases, computers on the private network behind one VPN peer may (by co-incidence) have IP addresses that are already used by computers on the network behind the other VPN peer. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent. To resolve issues related to ambiguous routing, see [Configuration overview on page 2079](#).

In other cases, computers on the private network behind one VPN peer may obtain IP addresses from a local DHCP server. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and/or IP-address overlap issues may arise. For a discussion of the related issues, see [FortiGate dialup-client configurations on page 1](#).

You can set up a fully meshed or partially meshed configuration (see below).

Fully meshed configuration

In a fully meshed network, all VPN peers are connected to each other, with one hop between peers. This topology is the most fault-tolerant: if one peer goes down, the rest of the network is not affected. This topology is difficult to scale because it requires connections between all peers. In addition, unnecessary communication can occur between peers. Best practices dictates a hub-and-spoke configuration instead (see [Hub-and-spoke configurations on page 1](#)).

Partially meshed configuration

A partially meshed network is similar to a fully meshed network, but instead of having tunnels between all peers, tunnels are only configured between peers that communicate with each other regularly.

Gateway-to-gateway configuration

The FortiGate units at both ends of the tunnel must be operating in NAT mode and have static public IP addresses.

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate that VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed by both FortiGate units:

- Define the Phase 1 parameters that the FortiGate unit needs to authenticate the remote peer and establish a secure connection.
- Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with the remote peer.
- Create security policies to control the permitted services and permitted direction of traffic between the IP source and destination addresses.

Configuring Phase 1 and Phase 2 for both peers

This procedure applies to both peers. Repeat the procedure on each FortiGate unit, using the correct IP address for each. You may wish to vary the Phase 1 names but this is optional. Otherwise all steps are the same for each peer.

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate FortiGate_2 and establish a secure connection. For the purposes of this example, a preshared key will be used to authenticate FortiGate_2. The same preshared key must be specified at both FortiGate units.

Before you define the Phase 1 parameters, you need to:

- Reserve a name for the remote gateway.
- Obtain the IP address of the public interface to the remote peer.
- Reserve a unique value for the preshared key.

The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must have a minimum of 16 randomly chosen alphanumeric characters.

At the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the remote peer. See [IPsec VPN in the web-based manager on page 2035](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**.

Name	Enter <code>peer_1</code> . A name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select Static IP Address .
IP Address	Enter <code>172.20.0.2</code> when configuring FortiGate_1. Enter <code>172.18.0.2</code> when configuring FortiGate_2. The IP address of the remote peer public interface.
Local Interface	Select wan1 .

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end point of the VPN tunnel. Before you define the Phase 2 parameters, you need to reserve a name for the tunnel. See [IPsec VPN in the web-based manager on page 2035](#).

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter a **Name** of `peer_1_p2`.
3. Select **peer_1** from the **Phase 1** drop-down menu.

Creating security policies

Security policies control all IP traffic passing between a source address and a destination address.

An IPsec security policy is needed to allow the transmission of encrypted packets, specify the permitted direction of VPN traffic, and select the VPN tunnel that will be subject to the policy. A single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Before you define security policies, you must first specify the IP source and destination addresses. In a gateway-to-gateway configuration:

- The IP source address corresponds to the private network behind the local FortiGate unit.
- The IP destination address refers to the private network behind the remote VPN peer.

When you are creating security policies, choose one of either route-based or policy-based methods and follow it for both VPN peers. DO NOT configure both route-based and policy-based policies on the same FortiGate unit for the same VPN tunnel.

The configuration of FortiGate_2 is similar to that of FortiGate_1. You must:

- Define the Phase 1 parameters that FortiGate_2 needs to authenticate FortiGate_1 and establish a secure connection.
- Define the Phase 2 parameters that FortiGate_2 needs to create a VPN tunnel with FortiGate_1.
- Create the security policy and define the scope of permitted services between the IP source and destination addresses.

When creating security policies it is good practice to include a comment describing what the policy does.

Creating firewall addresses

Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks.

To define the IP address of the network behind FortiGate_1

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `Finance_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet** of `10.21.101.0/24`.
5. Select **OK**.

To specify the address of the network behind FortiGate_2

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `HR_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet/IP Range** of `10.31.101.0/24`.
5. Select **OK**.

Creating route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

To create route-based VPN security policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.

3. Enter the following, and select **OK**.

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Source Address	Select Finance_network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name for the private network behind this FortiGate unit.
Outgoing Interface	Select peer_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address	Select HR_network when configuring FortiGate_1. Select Finance_network when configuring FortiGate_2. The address name that you defined for the private network behind the remote peer.
Action	Select ACCEPT .
Enable NAT	Disable.
Comments	Allow Internal to remote VPN network traffic.

4. Optionally, configure any additional features you may want, such as UTM or traffic shaping.
5. Select **Create New** to create another policy for the other direction.
6. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
7. Enter the following information, and select **OK**.

Incoming Interface	Select peer_1 . The VPN Tunnel (IPsec Interface) you configured.
Source Address	Select HR_network when configuring FortiGate_1. Select Finance_Network when configuring FortiGate_2. The address name defined for the private network behind the remote peer.
Outgoing Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.

Destination Address	Select Finance_Network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
Enable NAT	Disable.
Comments	Allow remote VPN network traffic to Internal.

8. Configure any additional features such as UTM or traffic shaping you may want. (optional).

All network traffic must have a static route to direct its traffic to the proper destination. Without a route, traffic will not flow even if the security policies are configured properly. You may need to create a static route entry for both directions of VPN traffic if your security policies allow bi-directional tunnel initiation.

To configure the route for a route-based VPN:

1. On FortiGate_2, go to **Network > Static Routes** and select **Create New**.
2. Enter the following information, and then select **OK**:

Destination IP / Mask	10.21.101.0/24
Device	FGT2_to_FGT1_Tunnel
Gateway	Leave as default: 0.0.0.0.
Distance (Advanced)	Leave this at its default. If there are other routes on this FortiGate unit, you may need to set the distance on this route so the VPN traffic will use it as the default route. However, this normally happens by default because this route is typically a better match than the generic default route.

Creating policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Complete the following:

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
---------------------------	--

Source Address	Select Finance_network when configuring FortiGate_1. Select HR_network when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Destination Address	Select HR_network when configuring FortiGate_1. Select Finance_network when configuring FortiGate_2.
VPN Tunnel	Select Use Existing and select peer_1 from the VPN Tunnel drop-down list. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.
Comments	Bidirectional policy-based VPN policy.

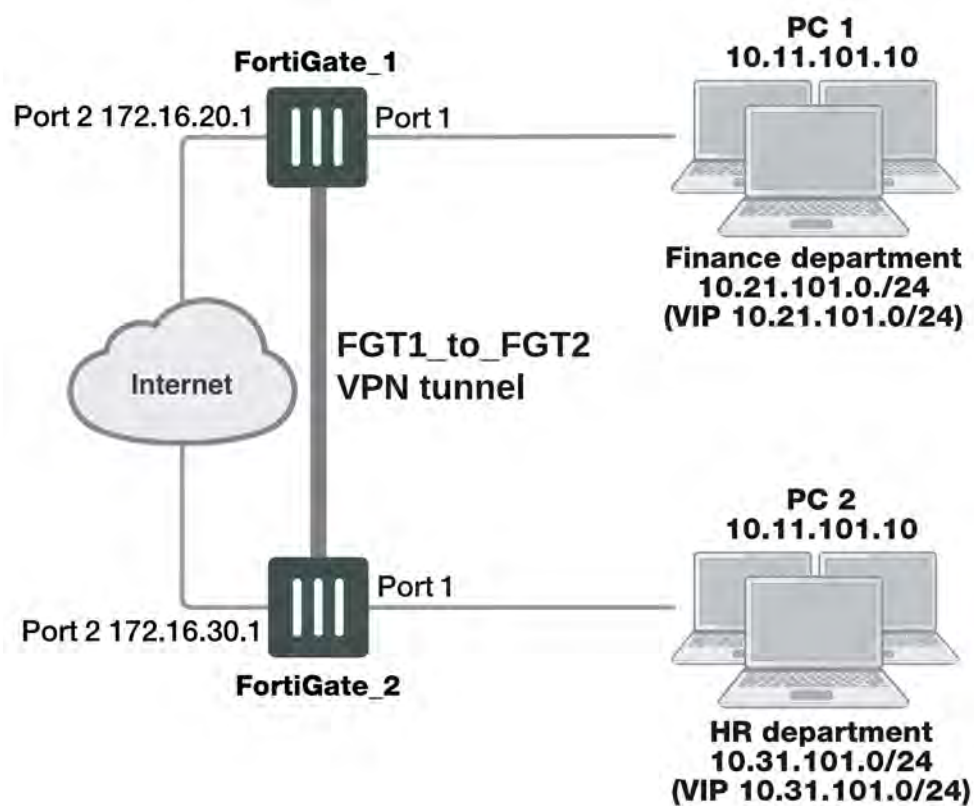

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

How to work with overlapping subnets

A site-to-site VPN configuration sometimes has the problem that the private subnet addresses at each end are the same. You can resolve this problem by remapping the private addresses using virtual IP addresses (VIP).

VIPs allow computers on those overlapping private subnets to each have another set of IP addresses that can be used without confusion. The FortiGate unit maps the VIP addresses to the original addresses. This means if PC1 starts a session with PC2 at 10.31.101.10, FortiGate_2 directs that session to 10.11.101.10 — the actual IP address of PC2. The figure below demonstrates this — Finance network VIP is 10.21.101.0/24 and the HR network is 10.31.101.0/24.

Overlapped subnets example

Solution for route-based VPN

You need to:

- Configure IPsec Phase 1 and Phase 2 as you usually would for a route-based VPN. In this example, the resulting IPsec interface is named `FGT1_to_FGT2`.
- Configure virtual IP (VIP) mapping:
 - the 10.21.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_1
 - the 10.31.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_2
- Configure an outgoing security policy with ordinary source NAT on both FortiGates.
- Configure an incoming security policy with the VIP as the destination on both FortiGates.
- Configure a route to the remote private network over the IPsec interface on both FortiGates.

To configure VIP mapping on both FortiGates

1. Go to **Policy & Objects > Virtual IPs** and create a new **Virtual IP**.
2. Enter the following information, and select **OK**:

Name	Enter a name, for example, <code>my_vip</code> .
External Interface	Select <code>FGT1_to_FGT2</code> . The IPsec interface.

VIP Type	Depending on both FortiGates, select one of the following options: <ul style="list-style-type: none"> • IPv4: If both FortiGates use IPv4 (Static NAT). • IPv6: If both FortiGates use IPv6 (Static NAT). • NAT46: Maps the IPv4 address into an IPv6 prefix. • NAT64: Maps the IPv6 address into an IPv4 prefix.
External IP Address/Range	For the External IP Address field enter: <p>10.21.101.1 when configuring FortiGate_1, or 10.31.101.1 when configuring FortiGate_2.</p>
Mapped IP Address/Range	For the Mapped IP Address enter 10.11.101.1. For the Range enter 10.11.101.254.
Port Forwarding	Disable

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the outbound security policy on both FortiGates

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Select Port 1 .
Outgoing Interface	Select FGT1_to_FGT2 . The IPsec interface.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT
NAT	Enable NAT .

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the inbound security policy on both FortiGates

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and then select **OK**:

Incoming Interface	Select FGT1_to_FGT2 .
---------------------------	------------------------------

Outgoing Interface	Select Port 1 . The IPsec interface.
Source	Select all .
Destination Address	Select my-vip .
Action	Select ACCEPT
NAT	Disable NAT .

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the static route for both FortiGates

1. Go to **Network > Static Routes** and create a new **Route** (or **IPv6 Route** as necessary).
2. Enter the following information, and then select **OK**:

Destination	Enter a subnet of 10.31.101.0/24 when configuring FortiGate_1. Enter a subnet of 10.21.101.0/24 when configuring FortiGate_2.
Device	Select FGT1_to_FGT2 .
Gateway	Leave as default: 0.0.0.0.
Administrative Distance	Leave at default (10). If you have advanced routing on your network, you may have to change this value.
Advanced Options	If you have advanced routing on your network, enable Advanced Options and enter a Priority .

Solution for policy-based VPN

As with the route-based solution, users contact hosts at the other end of the VPN using an alternate subnet address. PC1 communicates with PC2 using IP address 10.31.101.10, and PC2 communicates with PC1 using IP address 10.21.101.10.

In this solution however, outbound NAT is used to translate the source address of packets from the 10.11.101.0/24 network to the alternate subnet address that hosts at the other end of the VPN use to reply. Inbound packets from the remote end have their destination addresses translated back to the 10.11.101.0/24 network.

For example, PC1 uses the destination address 10.31.101.10 to contact PC2. Outbound NAT on FortiGate_1 translates the PC1 source address to 10.21.101.10. At the FortiGate_2 end of the tunnel, the outbound NAT configuration translates the destination address to the actual PC2 address of 10.11.101.10. Similarly, PC2 replies to PC1 using destination address 10.21.101.10, with the PC2 source address translated to 10.31.101.10. PC1 and PC2 can communicate over the VPN even though they both have the same IP address.

You need to:

- Configure IPsec Phase 1 as you usually would for a policy-based VPN.
- Configure IPsec Phase 2 with the `use-natip disable` CLI option.
- Define a firewall address for the local private network, 10.11.101.0/24.
- Define a firewall address for the remote private network:
 - Define a firewall address for 10.31.101.0/24 on FortiGate_1
 - Define a firewall address for 10.21.101.0/24 on FortiGate_2
- Configure an outgoing IPsec security policy with outbound NAT to map 10.11.101.0/24 source addresses:
 - To the 10.21.101.0/24 network on FortiGate_1
 - To the 10.31.101.0/24 network on FortiGate_2

To configure IPsec Phase 2 - CLI

```
config vpn ipsec phase2
  edit "FGT1_FGT2_p2"
    set keepalive enable
    set pfs enable
    set phase1name FGT1_to_FGT2
    set proposal 3des-sha1 3des-md5
    set replay enable
    set use-natip disable
  end
```

In this example, your Phase 1 definition is named `FGT1_to_FGT2`. `use-natip` is set to `disable`, so you can specify the source selector using the **`src-addr-type`**, `src-start-ip / src-end-ip` or `src-subnet` keywords. This example leaves these keywords at their default values, which specify the subnet `0.0.0.0/0`.

The `pfs` keyword ensures that perfect forward secrecy (PFS) is used. This ensures that each Phase 2 key created is unrelated to any other keys in use.

To define the local private network firewall address

1. Go to **Policy & Objects > Addresses** and create a new **Address**.
2. Enter the following information and select **OK**.

Category	Set to Address .
Name	Enter <code>vpn-local</code> . A meaningful name for the local private network.
Type	Set to IP/Netmask .
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	Set to any .

To define the remote private network firewall address

1. Go to **Policy & Objects > Addresses** and create a new **Address**.
2. Enter the following information, and select **OK**:

Category	Set to Address .
----------	-------------------------

Name	Enter <code>vpn-remote</code> . A meaningful name for the remote private network.
Type	Set to IP/Netmask .
Subnet / IP Range	10.31.101.0 255.255.255.0 on FortiGate_1. 10.21.101.0 255.255.255.0 on FortiGate_2.
Interface	Any

To configure the IPsec security policy

In the CLI on FortiGate_1, enter the commands:

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "vpn-local"
    set dstaddr "vpn-remote"
    set action ipsec
    set schedule "always"
    set service "ALL"
    set inbound enable
    set outbound enable
    set vpngateway "FGT1_to_FGT2"
    set natoutbound enable
    set natip 10.31.101.0 255.255.255.0
  end
```

Optionally, you can set everything except `natip` in the web-based manager and then use the CLI to set `natip`.

Enter the same commands on FortiGate_2, but set `natip` be `10.21.101.0 255.255.255.0`.

Testing

The best testing is to look at the packets both as the VPN tunnel is negotiated, and when the tunnel is up.

Determining what the other end of the VPN tunnel is proposing

1. Start a terminal program such as PuTTY and set it to log all output.
When necessary refer to the logs to locate information when output is verbose.
2. Logon to the FortiGate unit using a `super_admin` account.
3. Enter the following CLI commands.
4. Display all the possible IKE error types and the number of times they have occurred:

```
diag vpn ike errors
```

5. Check for existing debug sessions:

```
diag debug info
```

If a debug session is running, to halt it enter:

```
diag debug disable
```

6. Confirm your proposal settings:

```
diag vpn ike config list
```

7. If your proposal settings do not match what you expect, make a change to it and save it to force an update in memory. If that fixes the problem, stop here.

8. List the current vpn filter:

```
diag vpn ike filter
```

9. If all fields are set to any, there are no filters set and all VPN IKE packets will be displayed in the debug output. If your system has only a few VPNs, skip setting the filter.
If your system has many VPN connections this will result in very verbose output and make it very difficult to locate the correct connection attempt.

10. Set the VPN filter to display only information from the destination IP address for example 10.10.10.10:

```
diag vpn ike log-filter dst-addr4 10.10.10.10
```

To add more filter options, enter them one per line as above. Other filter options are:

clear	erase the current filter
dst-addr6	the IPv6 destination address range to filter by
dst-port	the destination port range to filter by
interface	interface that IKE connection is negotiated over
list	display the current filter
name	the phase1 name to filter by
negate	negate the specified filter parameter
src-addr4	the IPv4 source address range to filter by
src-addr6	the IPv6 source address range to filter by
src-port	the source port range to filter by
vd	index of virtual domain. 0 matches all

11. Start debugging:

```
diag debug app ike 255
diag debug enable
```

12. Have the remote end attempt a VPN connection.

If the remote end attempts the connection they become the initiator. This situation makes it easier to debug VPN tunnels because then you have the remote information and all of your local information. by initiate the connection, you will not see the other end's information.

13. If possible go to the web-based manager on your FortiGate unit, go to the VPN monitor and try to bring the tunnel up.
14. Stop the debug output:

```
diag debug disable
```

15. Go back through the output to determine what proposal information the initiator is using, and how it is different from your VPN P1 proposal settings.

Things to look for in the debug output of attempted VPN connections are shown below.

Important terms to look for in VPN debug output

initiator	Starts the VPN attempt, in the above procedure that is the remote end
responder	Answers the initiator's request
local ID	In aggressive mode, this is not encrypted
error no SA proposal chosen	There was no proposal match — there was no encryption-authentication pair in common, usually occurs after a long list of proposal attempts
R U THERE and R U THERE ack	dead peer detection (dpd), also known as dead gateway detection — after three failed attempts to contact the remote end it will be declared dead, no farther attempts will be made to contact it
negotiation result	lists the proposal settings that were agreed on
SA_life_soft and SA_life_ hard	negotiating a new key, and the key life
R U THERE	If you see this, it means Phase 1 was successful
tunnel up	the negotiation was successful, the VPN tunnel is operational

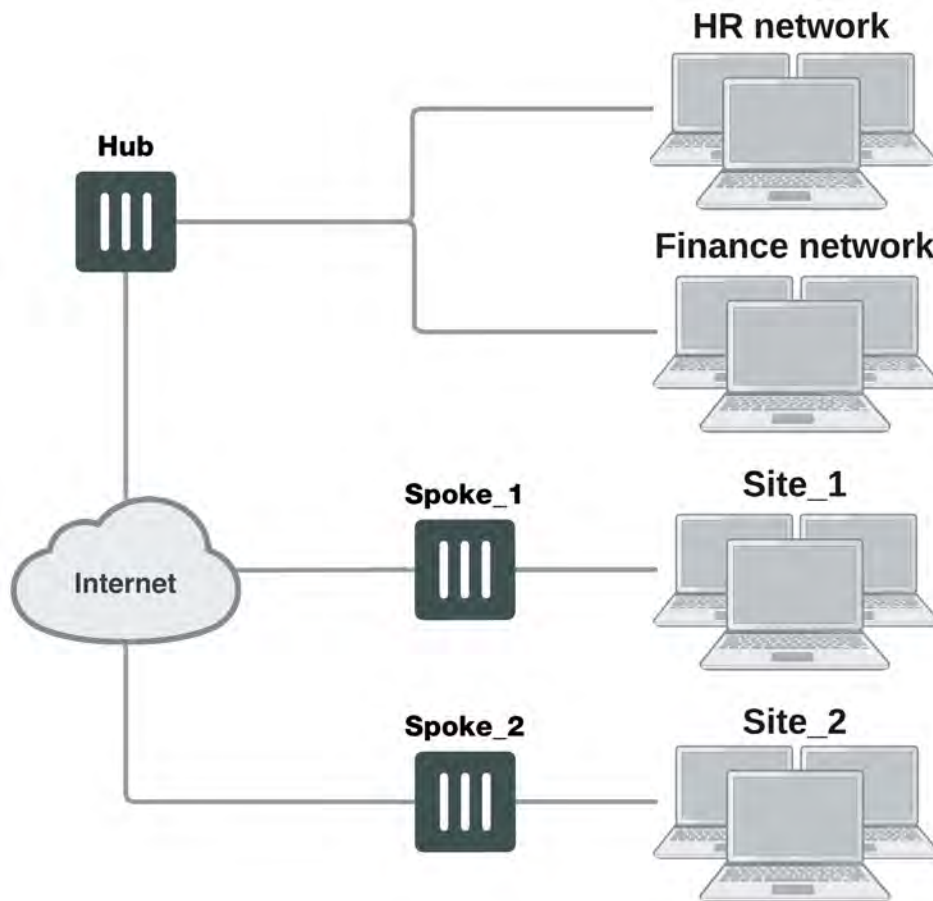

Hub-and-spoke configurations

This section describes how to set up hub-and-spoke IPsec VPNs. The following topics are included in this section:

Configuration overview

In a hub-and-spoke configuration, VPN connections radiate from a central FortiGate unit (the hub) to a number of remote peers (the spokes). Traffic can pass between private networks behind the hub and private networks behind the remote peers. Traffic can also pass between remote peer private networks through the hub.

Example hub-and-spoke configuration

The actual implementation varies in complexity depending on:

- Whether the spokes are statically or dynamically addressed
- The addressing scheme of the protected subnets
- How peers are authenticated

This guide discusses the issues involved in configuring a hub-and-spoke VPN and provides some basic configuration examples.

Hub-and-spoke infrastructure requirements

- The FortiGate hub must be operating in NAT mode and have a static public IP address.
- Spokes may have static IP addresses, dynamic IP addresses (see [FortiGate dialup-client configurations on page 2133](#)), or static domain names and dynamic IP addresses (see [Dynamic DNS configuration on page 2111](#)).

Spoke gateway addressing

The public IP address of the spoke is the VPN remote gateway as seen from the hub. Statically addressed spokes each require a separate VPN Phase 1 configuration on the hub. When there are many spokes, this becomes rather cumbersome.

Using dynamic addressing for spokes simplifies the VPN configuration because then the hub requires only a single Phase 1 configuration with “dialup user” as the remote gateway. You can use this configuration even if the remote peers have static IP addresses. A remote peer can establish a VPN connection regardless of its IP address if its traffic selectors match and it can authenticate to the hub. See [Configuration overview on page 2094](#) for an example of this configuration.

Protected networks addressing

The addresses of the protected networks are needed to configure destination selectors and sometimes for security policies and static routes. The larger the number of spokes, the more addresses there are to manage. You can

- Assign spoke subnets as part of a larger subnet, usually on a new network
- or
- Create address groups that contain all of the needed addresses

Using aggregated subnets

If you are creating a new network, where subnet IP addresses are not already assigned, you can simplify the VPN configuration by assigning spoke subnets that are part of a large subnet.

Aggregated subnets

All spokes use the large subnet address, 10.1.0.0/16 for example, as:

- The IPsec destination selector
- The destination of the security policy from the private subnet to the VPN (required for policy-based VPN, optional for route-based VPN)
- The destination of the static route to the VPN (route-based)

Each spoke uses the address of its own protected subnet as the IPsec source selector and as the source address in its VPN security policy. The remote gateway is the public IP address of the hub FortiGate unit.

Using an address group

If you want to create a hub-and-spoke VPN between existing private networks, the subnet addressing usually does not fit the aggregated subnet model discussed earlier. All of the spokes and the hub will need to include the addresses of all the protected networks in their configuration.

On FortiGate units, you can define a named firewall address for each of the remote protected networks and add these addresses to a firewall address group. For a policy-based VPN, you can then use this address group as the destination of the VPN security policy.

For a route-based VPN, the destination of the VPN security policy can be set to All. You need to specify appropriate routes for each of the remote subnets.

Authentication

Authentication is by a common pre-shared key or by certificates. For simplicity, the examples in this chapter assume that all spokes use the same pre-shared key.

Configure the hub

At the FortiGate unit that acts as the hub, you need to:

- Configure the VPN to each spoke
- Configure communication between spokes

You configure communication between spokes differently for a policy-based VPN than for a route-based VPN. For a policy-based VPN, you configure a VPN concentrator. For a route-based VPN, you must either define security policies or group the IPsec interfaces into a zone.

Define the hub-spoke VPNs

Perform these steps at the FortiGate unit that will act as the hub. Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Configuring the VPN hub

1. At the hub, define the Phase 1 configuration for each spoke. See [Phase 1 parameters on page 2048](#). Enter these settings in particular:

Name	Enter a name to identify the VPN in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	<p>The remote gateway is the other end of the VPN tunnel. There are three options:</p> <p>Static IP Address — Enter the spoke's public IP Address. You will need to create a Phase 1 configuration for each spoke. Either the hub or the spoke can establish the VPN connection.</p> <p>Dialup User — No additional information is needed. The hub accepts connections from peers with appropriate encryption and authentication settings. Only one Phase 1 configuration is needed for multiple dialup spokes. Only the spoke can establish the VPN tunnel.</p> <p>Dynamic DNS — If the spoke subscribes to a dynamic DNS service, enter the spoke's Dynamic DNS domain name. Either the hub or the spoke can establish the VPN connection. For more information, see Dynamic DNS configuration on page 1.</p>
Local Interface	Select the FortiGate interface that connects to the remote gateway. This is usually the FortiGate unit's public interface.

2. Define the Phase 2 parameters needed to create a VPN tunnel with each spoke. See [Phase 2 parameters on page 2067](#). Enter these settings in particular:

Name	Enter a name to identify this spoke Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined for this spoke.

IPsec VPN in ADVPN hub-and-spoke

IPsec VPN traffic is allowed through a tunnel between an ADVPN hub-and-spoke.

CLI Syntax:

```
config vpn ipsec phase1-interface
edit "int-fgtb"
```

```

...
set auto-discovery-sender [enable | disable]
set auto-discovery-receiver [enable | disable]
set auto-discovery-forwarder [enable | disable]
...
next
end
config vpn ipsec phase2-interface
edit "int-fgtb"
...
set auto-discovery-sender phase1 [enable | disable]
...
next
end

```

Define the hub-spoke security policies

1. Define a name for the address of the private network behind the hub. For more information, see [Defining policy addresses on page 1](#).
2. Define names for the addresses or address ranges of the private networks behind the spokes. For more information, see [Defining policy addresses on page 1](#).
3. Define the VPN concentrator. See [To define the VPN concentrator on page 2099](#).
4. Define security policies to permit communication between the hub and the spokes. For more information, see [Defining VPN security policies on page 1](#).

Route-based VPN security policies

Define ACCEPT security policies to permit communications between the hub and the spoke. You need one policy for each direction.

Adding policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
Outgoing Interface	Select the hub's interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 1.
Action	Select ACCEPT .
Enable NAT	Enable.

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
---------------------------	---

Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate units.
Outgoing Interface	Select the source address that you defined in Step 1.
Destination Address	Select the hub's interface to the internal (private) network.
Action	Select ACCEPT .
Enable NAT	Enable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the hub and the spoke.

Adding policies

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the hub's interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 1.
Outgoing Interface	Select the hub's public network interface.
Destination Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration that you created for the spoke in Step 1. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.

In the policy list, arrange the policies in the following order:

- IPsec policies that control traffic between the hub and the spokes first
- The default security policy last

Configuring communication between spokes (policy-based VPN)

For a policy-based hub-and-spoke VPN, you define a concentrator to enable communication between the spokes.

To define the VPN concentrator

1. At the hub, go to **VPN > IPsec Concentrator** and select **Create New**.
2. In the **Concentrator Name** field, type a name to identify the concentrator.
3. From the **Available Tunnels** list, select a VPN tunnel and then select the right-pointing arrow.
4. Repeat Step 3 until all of the tunnels associated with the spokes are included in the concentrator.
5. Select **OK**.

Configuring communication between spokes (route-based VPN)

For a route-based hub-and-spoke VPN, there are several ways you can enable communication between the spokes:

- Put all of the IPsec interfaces into a zone and enable intra-zone traffic. This eliminates the need for any security policy for the VPN, but you cannot apply UTM features to scan the traffic for security threats.
- Put all of the IPsec interfaces into a zone and create a single zone-to-zone security policy
- Create a security policy for each pair of spokes that are allowed to communicate with each other. The number of policies required increases rapidly as the number of spokes increases.

Using a zone as a concentrator

A simple way to provide communication among all of the spokes is to create a zone and allow intra-zone communication. You cannot apply UTM features using this method.

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Clear **Block intra-zone traffic**.
5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

Using a zone with a policy as a concentrator

If you put all of the hub IPsec interfaces involved in the VPN into a zone, you can enable communication among all of the spokes and apply UTM features with just one security policy.

Creating a zone for the VPN

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Select **Block intra-zone traffic**.
5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

Creating a security policy for the zone

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the settings: and select **OK**.

Incoming Interface	Select the zone you created for your VPN.
Source Address	Select All .
Outgoing Interface	Select the zone you created for your VPN.

Destination Address	Select All .
Action	Select ACCEPT .
Enable NAT	Enable.

Using security policies as a concentrator

To enable communication between two spokes, you need to define an ACCEPT security policy for them. To allow either spoke to initiate communication, you must create a policy for each direction. This procedure describes a security policy for communication from Spoke 1 to Spoke 2. Others are similar.

1. Define names for the addresses or address ranges of the private networks behind each spoke. For more information, see [Defining policy addresses on page 1](#).
2. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
3. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
4. Enter the settings and select **OK**.

Incoming Interface	Select the IPsec interface that connects to Spoke 1.
Source Address	Select the address of the private network behind Spoke 1.
Outgoing Interface	Select the IPsec interface that connects to Spoke 2.
Destination Address	Select the address of the private network behind Spoke 2.
Action	Select ACCEPT .
Enable NAT	Enable.

Configure the spokes

Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Perform these steps at each FortiGate unit that will act as a spoke.

Creating the Phase 1 and phase_2 configurations

1. At the spoke, define the Phase 1 parameters that the spoke will use to establish a secure connection with the hub. See [Phase 1 parameters on page 2048](#). Enter these settings:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the interface that connects to the hub.

2. Create the Phase 2 tunnel definition. See [Phase 2 parameters on page 2067](#). Select the set of Phase 1 parameters that you defined for the hub. You can select the name of the hub from the **Static IP Address** part of the list.

Configuring security policies for hub-to-spoke communication

1. Create an address for this spoke. See [Defining policy addresses on page 1](#). Enter the IP address and netmask of the private network behind the spoke.
2. Create an address to represent the hub. See [Defining policy addresses on page 1](#). Enter the IP address and netmask of the private network behind the hub.
3. Define the security policy to enable communication with the hub.

Route-based VPN security policy

Define two security policies to permit communications to and from the hub.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the hub address you defined in Step 1.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select the spoke addresses you defined in Step 2.
Action	Select ACCEPT .
Enable NAT	Enable

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the hub destination addresses you defined in Step 2.
Action	Select ACCEPT .
Enable NAT	Enable

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the hub. See [Defining VPN security policies on page 1](#).

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.

Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the hub address you defined in Step 2.
VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration you defined. Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.

Configuring security policies for spoke-to-spoke communication

Each spoke requires security policies to enable communication with the other spokes. Instead of creating separate security policies for each spoke, you can create an address group that contains the addresses of the networks behind the other spokes. The security policy then applies to all of the spokes in the group.

1. Define destination addresses to represent the networks behind each of the other spokes. Add these addresses to an address group.
2. Define the security policy to enable communication between this spoke and the spokes in the address group you created.

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the other spokes. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Route-based VPN security policy

Define two security policies to permit communications to and from the other spokes.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the spoke address group you defined in Step " Configure the spokes " on page 2101.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select this spoke's address name.
Action	Select ACCEPT .
Enable NAT	Enable

4. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select the spoke's interface to the internal (private) network.
---------------------------	---

Source Address	Select this spoke's address name.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the spoke address group you defined in Step 1.
Action	Select ACCEPT .
Enable NAT	Enable

Policy-based VPN security policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following:

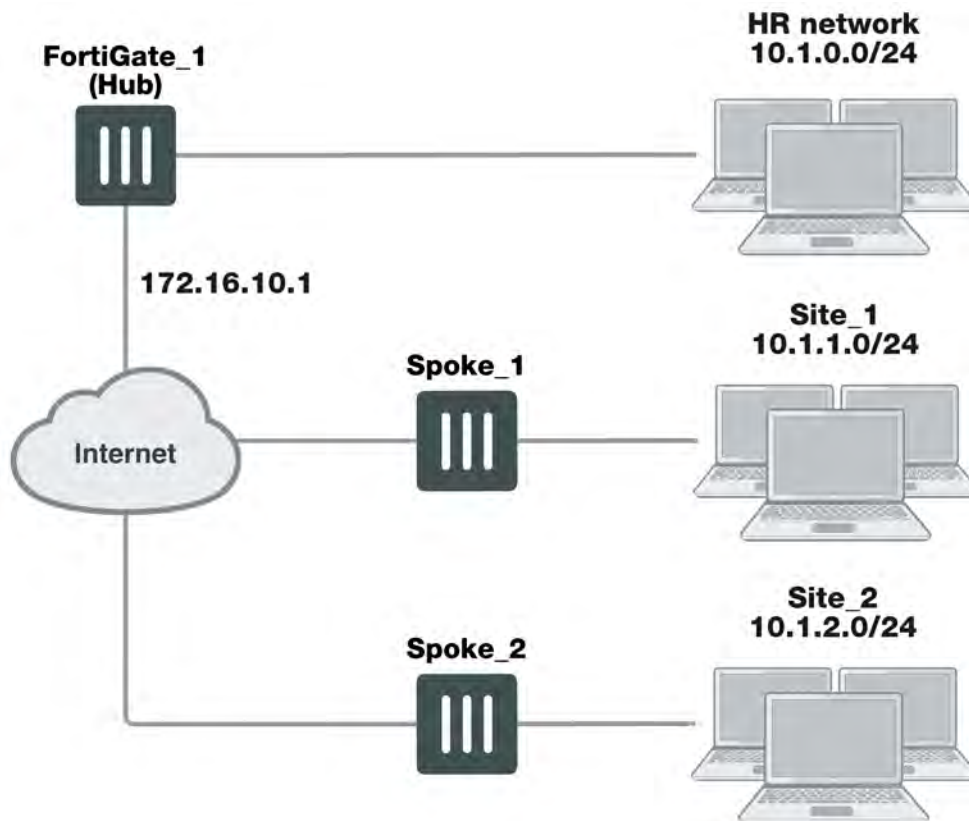

Incoming Interface	Select this spoke's internal (private) network interface.
Source Address	Select this spoke's source address.
Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the spoke address group you defined in Step 1.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 1 configuration you defined.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

Place this policy or policies in the policy list above any other policies having similar source and destination addresses.

Dynamic spokes configuration example

This example demonstrates how to set up a basic route-based hub-and-spoke IPsec VPN that uses preshared keys to authenticate VPN peers.

Example hub-and-spoke configuration

In the example configuration, the protected networks 10.1.0.0/24, 10.1.1.0/24 and 10.1.2.0/24 are all part of the larger subnet 10.1.0.0/16. The steps for setting up the example hub-and-spoke configuration create a VPN among Site 1, Site 2, and the HR Network.

The spokes are dialup. Their addresses are not part of the configuration on the hub, so only one spoke definition is required no matter the number of spokes. For simplicity, only two spokes are shown.

In an ADVPN topology, any two pair of peers can create a shortcut, as long as one of the devices is not behind NAT.

The on-the-wire format of the ADVPN messages use TLV encoding. Because of this, this feature is not compatible with any previous ADVPN builds.

Configure the hub (FortiGate_1)

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate spokes and establish secure connections.

For the purposes of this example, one preshared key will be used to authenticate all of the spokes. Each key must contain at least 6 printable characters and best practices dictates that it only be known by network administrators. For optimum protection against currently known attacks, each key must consist of a minimum of 16 randomly chosen alphanumeric characters.

Define the IPsec configuration

1. At FortiGate_1, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Define the Phase 1 parameters that the hub will use to establish a secure connection to the spokes.

Name	Enter a name (for example, <code>toSpokes</code>).
Remote Gateway	Dialup user
Local Interface	External
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end points of the VPN tunnels.

3. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
4. Enter the following information, and select **OK**:

Name	Enter a name for the Phase 2 definition (for example, <code>toSpokes_ph2</code>).
Phase 1	Select the Phase 1 configuration that you defined previously (for example, <code>toSpokes</code>).

Define the security policies

security policies control all IP traffic passing between a source address and a destination address. For a route-based VPN, the policies are simpler than for a policy-based VPN. Instead of an IPSEC policy, you use an ACCEPT policy with the virtual IPsec interface as the external interface.

Before you define security policies, you must first define firewall addresses to use in those policies. You need addresses for:

- The HR network behind FortiGate_1
- The aggregate subnet address for the protected networks

Defining the IP address of the HR network behind FortiGate_1

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Enter an address name (for example, <code>HR_Network</code>).
-------------	--

Type	Subnet
Subnet/IP Range	Enter the IP address of the HR network behind FortiGate_1 (for example, 10.1.0.0/24).

Specifying the IP address the aggregate protected subnet

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Address Name	Enter an address name (for example, Spoke_net).
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, 10.1.0.0/16

Defining the security policy for traffic from the hub to the spokes

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**,
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the HR network, port 1 .
Source Address	Select HR_Network .
Outgoing Interface	Select the virtual IPsec interface that connects to the spokes, toSpokes .
Destination Address	Select Spoke_net .
Action	Select ACCEPT .

Place the policy in the policy list above any other policies having similar source and destination addresses.

Configure communication between spokes

Spokes communicate with each other through the hub. You need to configure the hub to allow this communication. An easy way to do this is to create a zone containing the virtual IPsec interfaces even if there is only one, and create a zone-to-zone security policy.

1. Go to **Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as **Our_VPN_zone**.
4. Select **Block intra-zone traffic**.
You could enable intra-zone traffic and then you would not need to create a security policy. But, you would not be able to apply UTM features.
5. In **Interface Members**, select the virtual IPsec interface, **toSpokes**.
6. Select **OK**.

Creating a security policy for the zone

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select <code>Our_VPN_zone</code> .
Source Address	Select All .
Outgoing Interface	Select <code>Our_VPN_zone</code> .
Destination Address	Select All .
Action	Select ACCEPT .
Enable NAT	Enable.

4. Select **OK**.

Configure the spokes

In this example, all spokes have nearly identical configuration, requiring the following:

- Phase 1 authentication parameters to initiate a connection with the hub.
- Phase 2 tunnel creation parameters to establish a VPN tunnel with the hub.
- A source address that represents the network behind the spoke. This is the only part of the configuration that is different for each spoke.
- A destination address that represents the aggregate protected network.
- A security policy to enable communications between the spoke and the aggregate protected network

Define the IPsec configuration

At each spoke, create the following configuration.

1. At the spoke, go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Enter the following information:

Name	Type a name, for example, <code>toHub</code> .
Remote Gateway	Select Static IP Address .
IP Address	Enter <code>172.16.10.1</code> .
Local Interface	Select Port2 .
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. The value must be identical to the preshared key that you specified previously in the <code>FortiGate_1</code> configuration

Peer Options	Select Any peer ID .
---------------------	-----------------------------

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter the following information and select **OK**:

Name	Enter a name for the tunnel, for example, <code>toHub_ph2</code> .
Phase 1	Select the name of the Phase 1 configuration that you defined previously, for example, <code>toHub</code> .
Advanced	Select to show the following Quick Mode Selector settings.
Source	Enter the address of the protected network at this spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .
Destination	Enter the aggregate protected subnet address, <code>10.1.0.0/16</code> .

Define the security policies

You need to define firewall addresses for the spokes and the aggregate protected network and then create a security policy to enable communication between them.

Defining the IP address of the network behind the spoke

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example <code>LocalNet</code> .
Type	Subnet
Subnet/IP Range	Enter the IP address of the private network behind the spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .

Specifying the IP address of the aggregate protected network

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example, <code>Spoke_net</code> .
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, <code>10.1.0.0/16</code> .

Defining the security policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information:

Incoming Interface	Select the virtual IPsec interface, <code>toHub</code> .
Source Address	Select the aggregate protected network address <code>Spoke_net</code> .
Outgoing Interface	Select the interface to the internal (private) network, <code>port1</code> .
Destination Address	Select the address for this spoke's protected network <code>LocalNet</code> .
Action	Select ACCEPT .

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the internal private network, <code>port1</code> .
Source Address	Select the address for this spoke's protected network, <code>LocalNet</code> .
Outgoing Interface	Select the virtual IPsec interface, <code>toHub</code> .
Destination Address	Select the aggregate protected network address, <code>Spoke_net</code> .
Action	Select ACCEPT .

Place these policies in the policy list above any other policies having similar source and destination addresses.

Dynamic DNS configuration

This section describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a domain name and a dynamic IP address.

The following topics are included in this section:

Dynamic DNS over VPN concepts

A typical computer has a static IP address and one or more DNS servers to resolve fully qualified domain names (FQDN) into IP addresses. A domain name assigned to this computer is resolved by any DNS server having an entry for the domain name and its static IP address. The IP address never changes or changes only rarely so the DNS server can reliably say it has the correct address for that domain all the time.

Dynamic DNS (DDNS)

It is different when a computer has a dynamic IP address, such as an IP address assigned dynamically by a DHCP server, and a domain name. Computers that want to contact this computer do not know what its current IP address is. To solve this problem there are dynamic DNS (DDNS) servers. These are public servers that store a DNS entry for your computer that includes its current IP address and associated domain name. These entries are kept up to date by your computer sending its current IP address to the DDNS server to ensure its entry is always up to date. When other computers want to contact your domain, their DNS gets your IP address from your DDNS server. To use DDNS servers, you must subscribe to them and usually pay for their services.

When configuring DDNS on your FortiGate unit, go to **Network > DNS** and enable **Enable FortiGuard DDNS**. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

Routing

When an interface has some form of changing IP address (DDNS, PPPoE, or DHCP assigned address), routing needs special attention. The standard static route cannot handle the changing IP address. The solution is to use the dynamic-gateway command in the CLI. Say for example you already have four static routes, and you have a PPPoE connection over the wan2 interface and you want to use that as your default route.

The route is configured on the dynamic address VPN peer trying to access the static address FortiGate unit.

Configuring dynamic gateway routing - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-gateway enable
    set device wan2
  next
end
```

DDNS over VPN

IPsec VPN expects an IP address for each end of the VPN tunnel. All configuration and communication with that tunnel depends on the IP addresses as reference points. However, when the interface the tunnel is on has DDNS enabled there is no set IP address. The remote end of the VPN tunnel now needs another way to reference your end of the VPN tunnel. This is accomplished using Local ID.

A FortiGate unit that has a domain name and a dynamic IP address can initiate VPN connections anytime. The remote peer can reply to the local FortiGate unit using the source IP address that was sent in the packet header because it is current. Without doing a DNS lookup first, the remote peer runs the risk of the dynamic IP changing before it attempts to connect. To avoid this, the remote peer must perform a DNS lookup for the domain name of to be sure of the dynamic IP address before initiating the connection.

Remote Gateway

When configuring the Phase 1 entry for a VPN tunnel, the Remote Gateway determines the addressing method the remote end of the tunnel uses as one of Static IP Address, Dialup User, or Dynamic DNS. There are different fields for each option.

When you select the Dynamic DNS VPN type there is a related field called Dynamic DNS. The Dynamic DNS field is asking for the FQDN of the remote end of the tunnel. It uses this information to look up the IP address of the remote end of the tunnel through the DDNS server associated with that domain name.

Local ID (peer ID)

The Local ID or peer ID can be used to uniquely identify one end of a VPN tunnel. This enables a more secure connection. Also if you have multiple VPN tunnels negotiating, this ensures the proper remote and local ends connect. When you configure it on your end, it is your Local ID. When the remote end connects to you, they see it as your peer ID.

If you are debugging a VPN connection, the Local ID is part of the VPN negotiations. You can use it to help troubleshoot connection problems.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

Configuring your Local ID

1. Go to **VPN > IPsec Wizard** and create the new custom tunnel or go to **VPN > IPsec Tunnels** and edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert To Custom Tunnel** button).
3. In the **Phase 1 Proposal** section, enter your **Local ID**.
4. Select **OK**.

The default configuration is to accept all local IDs (peer IDs). If you have **Local ID** set, the remote end of the tunnel must be configured to accept your local ID.

Accepting a specific Peer ID

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Authentication** (if it is not available, you may need to click the **Convert To Custom Tunnel** button).

3. Set **Mode** to **Aggressive**.
4. For **Peer Options**, select **This peer ID**. This option becomes visible only when **Aggressive** mode is selected.
5. In the **Peer ID** field, enter the string the other end of the tunnel used for its local ID.
6. Configure the rest of the Phase 1 entry as required.
7. Select **OK**.

Route-based or policy-based VPN

VPN over dynamic DNS can be configured with either route-based or policy-based VPN settings. Both are valid, but have differences in configuration. Choose the best method based on your requirements. For more information on route-based and policy-based, see [IPsec VPN overview on page 2031](#).

Route-based VPN configuration requires two security policies to be configured (one for each direction of traffic) to permit traffic over the VPN virtual interface, and you must also add a static route entry for that VPN interface or the VPN traffic will not reach its destination. See [Dynamic DNS configuration on page 2111](#) and [Dynamic DNS configuration on page 2111](#).

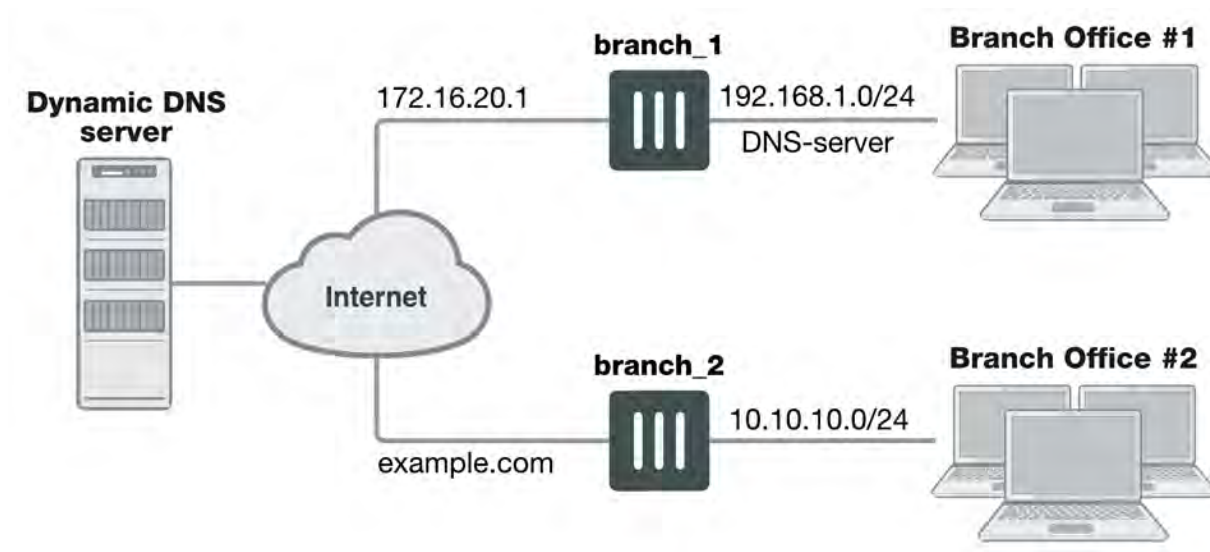

Policy-based VPN configuration uses more complex and often more IPsec security policies, but does not require a static route entry. It has the benefit of being able to configure multiple policies for handling multiple protocols in different ways, such as more scanning of less secure protocols or guaranteeing a minimum bandwidth for protocols such as VoIP. See [Dynamic DNS configuration on page 2111](#) and [Dynamic DNS configuration on page 2111](#).

DDNS topology

In this scenario, two branch offices each have a FortiGate unit and are connected in a gateway-to-gateway VPN configuration. One FortiGate unit has a domain name (example.com) with a dynamic IP address. See `branch_2` in the figure below.

Whenever the `branch_2` unit connects to the Internet (and possibly also at predefined intervals set by the ISP), the ISP may assign a different IP address to the FortiGate unit. The unit has its domain name registered with a dynamic DNS service. The `branch_2` unit checks in with the DDNS server on a regular basis, and that server provides the DNS information for the domain name, updating the IP address from time to time. Remote peers have to locate the `branch_2` FortiGate unit through a DNS lookup each time to ensure the address they get is current and correct.

Example dynamic DNS configuration

When a remote peer (such as the `branch_1` FortiGate unit above) initiates a connection to `example.com`, the local DNS server looks up and returns the IP address that matches the domain name `example.com`. The remote peer uses the retrieved IP address to establish a VPN connection with the `branch_2` FortiGate unit.

Assumptions

- You have administrator access to both FortiGate units.
- Both FortiGate units have interfaces named `wan1` and `internal`. (If not, you can use the alias feature to assign these labels as “nicknames” to other interfaces to follow this example.)
- Both FortiGate units have the most recent firmware installed, have been configured for their networks, and are currently passing normal network traffic.
- The `branch_2` FortiGate unit has its `wan1` interface defined as a dynamic DNS interface with the domain name of **example.com**.
- A basic gateway-to-gateway configuration is in place (see [Gateway-to-gateway configurations on page 1](#)) except one of the FortiGate units has a static domain name and a dynamic IP address instead of a static IP address.
- The FortiGate unit with the domain name is subscribed to one of the supported dynamic DNS services. Contact one of the services to set up an account.

Configuration overview

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate the VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed:

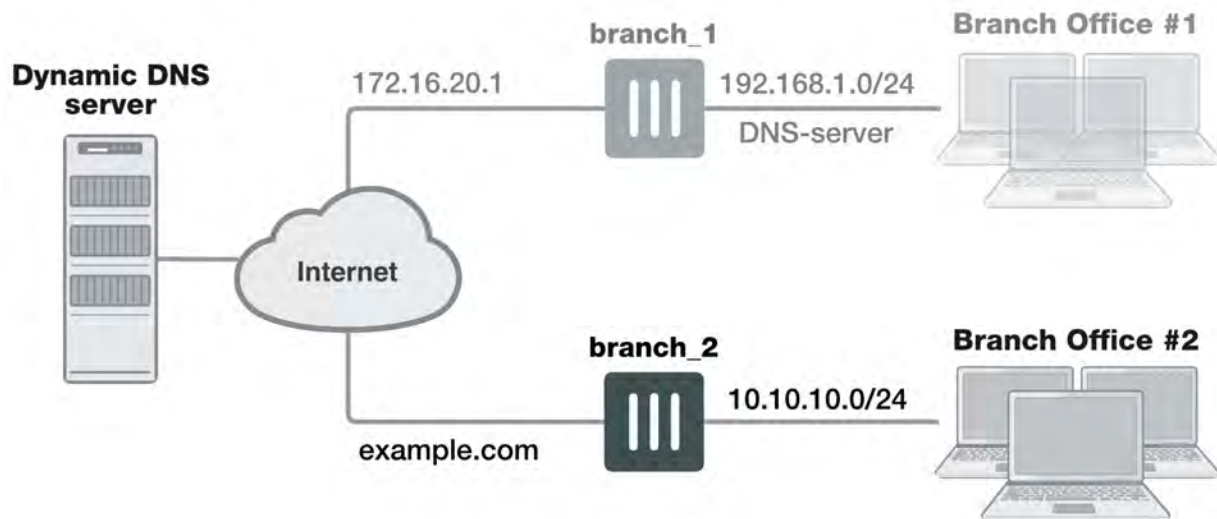

- Configure the `branch_2` FortiGate unit with the dynamic IP address. This unit uses a Local ID string instead of an IP address to identify itself to the remote peer. See [Configuring the dynamically-addressed VPN peer](#) below, which is made up of configuring `branch_2`'s VPN tunnel settings and security policies.

- Configure the fixed-address VPN peer. To initiate a VPN tunnel with the dynamically-addressed peer, this unit must first retrieve the IP address for the domain from the dynamic DNS service. See [Configuring the fixed-address VPN peer](#), which is made up of configuring branch_1's VPN tunnel settings and security policies.

Configuring the dynamically-addressed VPN peer

It is assumed that this FortiGate unit (branch_2) has already had its public facing interface, for example the wan1, configured with the proper dynamic DNS configuration.

Configuring branch_2, the dynamic address side

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. See [Phase 1 parameters on page 2048](#). During this procedure you need to choose if you will be using route-based or policy-based VPNs.

- Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
- Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
- Enter the following information:

Remote Gateway	<p>Select Static IP Address.</p> <p>The remote peer this FortiGate is connecting to has a static IP public address.</p> <p>If the remote interface is PPPoE do not select Retrieve default gateway from server.</p>
IP Address	Enter 172.16.20.1, the IP address of the public interface to the remote peer.
Interface	Select the Internet-facing interface wan1 (selected by default).
NAT Traversal	Select Enable (selected by default).

Keepalive Frequency	Enter a keepalive frequency (In seconds; set to 10 by default).
Dead Peer Detection	<p>Select a dead peer detection option. On Idle will attempt to reestablish VPN tunnels when a connection becomes idle (the idle interval is not a negotiated value).</p> <p>Use of periodic dead peer detection incurs extra overhead. When communicating to large numbers of IKE peers, you should consider using On Demand. (set to On Demand by default).</p>

4. Edit **Authentication** and complete the following:

Mode	Select Aggressive .
-------------	----------------------------

5. Edit **Phase 1 Proposal** and complete the following:

Local ID	<p>Enter <code>example.com</code>.</p> <p>A character string used by the <code>branch_2</code> FortiGate unit to identify itself to the remote peer.</p> <p>This value must be identical to the value in the This peer ID field of the Phase 1 remote gateway configuration on the <code>branch_1</code> remote peer. See Configuration overview on page 2114.</p>
-----------------	---

6. Open the **Phase 2 Selectors** panel.
Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For details on Phase 2, see [Phase 2 parameters on page 2067](#).
7. Enter the following information and select **OK**.

Name	Automatically entered as the name of the VPN tunnel.
Phase 1	<p>Select <code>branch_2</code>.</p> <p>The name of the Phase 1 configuration that you defined earlier.</p>

Define security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

After defining the two address ranges, select one of [Creating branch_2 route-based security policies on page 2117](#) or [Creating branch_2 policy-based security policies on page 2119](#) to configure the appropriate VPN policies.

Define VPN connection names for the address ranges of the private networks. These addresses are used in the security policies that permit communication between the networks. For more information, see [Defining VPN security policies on page 1](#).

Define an address name for the IP address and netmask of the private network behind the local FortiGate unit.

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**.
3. Enter the following information, and select **OK**.

Name	Enter <code>branch_2_internal</code> . Enter a meaningful name.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
Interface	Select internal . The interface that will be handling the traffic from the internal network.

Define an address name for the IP address and netmask of the private network behind the remote peer.

4. Select **Create New**.
5. Enter the following information, and select **OK**.

Name	Enter <code>branch_1_internal</code> . A meaningful name for the private network at the remote end of the VPN tunnel.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>192.168.1.0/24</code> . Include the netmask. Optionally you can specify a range
Interface	Select any . The interface that will be handling the remote VPN traffic on this FortiGate unit. If you are unsure, or multiple interfaces may be handling this traffic use <code>any</code> .

Creating branch_2 route-based security policies

Define ACCEPT security policies to permit communication between the branch_2 and branch_1 private networks. Once the route-based policy is configured a routing entry must be configured to route traffic over the VPN interface.

Define a policy to permit the branch_2 local FortiGate unit to initiate a VPN session with the branch_1 VPN peer.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select branch_2 . The VPN Tunnel (IPsec Interface).

Source	Select branch_2_internal . Select the address name for the private network behind this FortiGate unit.
Destination Address	Select branch_1_internal . The address name the private network behind the remote peer.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Route-based: Initiate a branch_2 to branch_1 VPN tunnel.

Define a policy to permit the branch_1 remote VPN peer to initiate VPN sessions.

3. Select **Create New**.
4. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select branch_2 . The VPN Tunnel (IPsec Interface).
Outgoing Interface	Select internal . The interface connecting the private network behind this FortiGate unit.
Source	Select branch_1_internal . The address name for the private network behind the remote peer.
Destination Address	Select branch_2_internal . The address name for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Route-based: Initiate a branch_1 to branch_2 internal VPN tunnel.

5. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
6. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Creating routing entry for VPN interface - CLI

```
config router static
edit 5
set dst 0.0.0.0 0.0.0.0
set dynamic-gateway enable
set device wan1
next
end
```

This routing entry must be added in the CLI because the dynamic-gateway option is not available in the web-based manager.

Creating branch_2 policy-based security policies

Define an IPsec policy to permit VPN sessions between the private networks. Define an IPsec policy to permit the VPN sessions between the local branch_2 unit and the remote branch_1 unit.

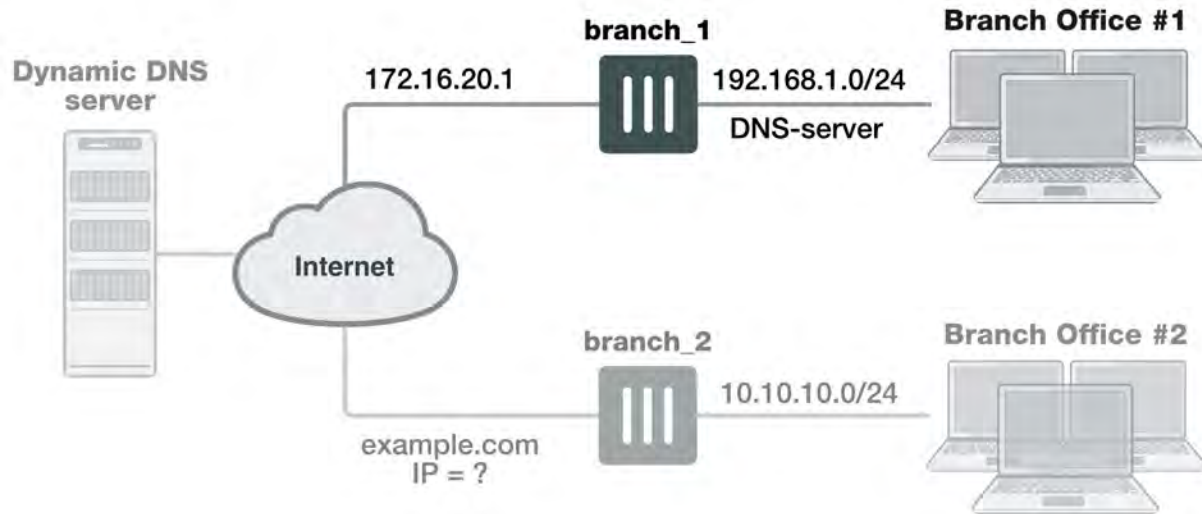

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select internal . The interface connecting the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Source	Select branch_2_internal . The address name for the private network behind this local FortiGate unit.
Destination Address	Select branch_1_internal . The address name for the private network behind branch_1, the remote peer.
Action	Select IPsec . Under VPN Tunnel , select branch_2 from the drop-down list. The name of the Phase 1 tunnel. Select Allow traffic to be initiated from the remote site .
Comments	Policy-based: allows traffic in either direction to initiate the VPN tunnel.

3. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
4. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Configuring the fixed-address VPN peer

The fixed-address VPN peer, branch_1, needs to retrieve the IP address from the dynamic DNS service to initiate communication with the dynamically-addressed peer, branch_2. It also depends on the peer ID (local ID) to initiate the VPN tunnel with branch_2.

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. For more information, see [Phase 1 parameters on page 2048](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information and select **OK**.

Remote Gateway	Select Dynamic DNS . The remote peer this FortiGate is connecting to has a dynamic IP address.
Dynamic DNS	Type the fully qualified domain name of the remote peer (for example, <code>example.com</code>).
Interface	Select wan1 . The public facing interface on the fixed-address FortiGate unit.
Mode Config	Select Aggressive .
Peer Options	Select This peer ID , and enter <code>example.com</code> . This option only appears when the mode is set to Aggressive. The identifier of the FortiGate unit with the dynamic address.

4. Edit **Authentication**, enter the following information and select **OK**.

Peer Options	Select This peer ID , and enter <code>example.com</code> . This option only appears when the authentication method is set to Signature . The identifier of the FortiGate unit with the dynamic address.
---------------------	---

5. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See [Phase 2 parameters on page 2067](#). Enter these settings in particular:

Name	Enter <code>branch_1_p2</code> . A name to identify this Phase 2 configuration.
-------------	---

Phase 1Select **branch_1**.

The name of the Phase 1 configuration that you defined for the remote peer. You can select the name of the remote gateway from the Dynamic DNS part of the list.

The `branch_1` FortiGate unit has a fixed IP address and will be connecting to the `branch_2` FortiGate unit that has a dynamic IP address and a domain name of `example.com`. Remember if you are using route-based security policies that you must add a route for the VPN traffic.

Defining address ranges for branch_1 security policies

As with `branch_2` previously, `branch_1` needs address ranges defined as well. See [Defining policy addresses on page 1](#).

1. Go to **Policy & Objects > Addresses** and select **Create New > Address**.
2. Enter the following information, and select **OK**.

Name	Enter <code>branch_2_internal</code> . A meaningful name for the private network behind the <code>branch_2</code> FortiGate unit.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
Interface	Select internal . This is the interface on this FortiGate unit that will be handling with this traffic.

3. Define an address name for the IP address and netmask of the private network behind the remote peer.
4. Create another address. Enter the following information, and select **OK**.

Name	Enter <code>branch_1_internal</code> . A meaningful name for the private network behind the <code>branch_1</code> peer.
Type	Select IP/Netmask .
Subnet / IP Range	Enter <code>192.168.1.0/24</code> . Include the netmask or specify a specific range.
Interface	Select any . The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use <code>any</code> .

Creating branch_1 route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See [Defining VPN security policies on page 1](#).

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select internal . The interface that connects to the private network behind the <code>branch_1</code> FortiGate unit.
Outgoing Interface	Select branch_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Source	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select branch_2_internal . The address name that you defined for the private network behind the <code>branch_2</code> peer.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	Internal -> branch2

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

3. Select **Create New**.
4. Enter the following information, and select **OK**.

Name	Enter an appropriate name for the policy.
Incoming Interface	Select branch_1 . The VPN Tunnel (IPsec Interface) you configured earlier.
Outgoing Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Source	Select branch_2_internal . The address name that you defined for the private network behind the <code>branch_2</code> remote peer.
Destination Address	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Action	Select ACCEPT .
NAT	Disable NAT .
Comments	branch_2 -> Internal

Creating branch_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Select internal . The interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select wan1 . The FortiGate unit's public interface.
Source	Select branch_1_internal . The address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select branch_2_internal . The address name that you defined for the private network behind the remote peer.
Action	Select IPsec . Under VPN Tunnel , select branch_1 from the drop-down list. The name of the Phase 1 tunnel. Select Allow traffic to be initiated from the remote site .

- Place this security policy in the policy list above any other policies having similar source and destination addresses.

Results

Once both ends are configured, you can test the VPN tunnel.

To test the VPN initiated by branch_2

- On branch_2, go to **Monitor > IPsec Monitor**.
All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.
- Select the tunnel listed for branch_2, and select the status column for that entry.
The status will say **Bring Up** and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you right-click and select **Bring Up**, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, Bring Up will change to Active, and the arrow icon will change to a green up arrow icon.
- If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

To test the VPN initiated by branch_1

- On branch_1, go to **Monitor > IPsec Monitor**.
- Select the tunnel listed for branch_1, and select the status column.
The difference between branch_2 and branch_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.
- If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the Phase 1 and Phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the Phase 1 configuration, and that branch_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information, see [Troubleshooting on page 1](#).

FortiClient dialup-client configuration

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispam and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically.

The following topics are included in this section:

Configuration overview

Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see [Phase 1 parameters on page 2048](#)). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See [Automatic configuration of FortiClient dialup clients on page 2125](#).

Example FortiClient dialup-client configuration

Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the Phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. If configured, the FortiGate unit could also require FortiClient registration, that is, the remote user would be required to have FortiClient installed before connection is completed.

Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their username and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec Phase 1 and Phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec Phase 1 connection and Phase 2 tunnel with the FortiGate unit.

FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See [Configuring the FortiGate unit on page 2127](#).

3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See [Configure the FortiClient Endpoint Security application on page 2132](#).

Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client's host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host's routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can ensure this by reserving a range of IP addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the "dhcp reserved-address" section in the "system" chapter of the [FortiGate CLI Reference](#).

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example, in Windows command prompt, type `ipconfig /all`

On Linux or Mac OS X, type `ifconfig` in a terminal window. The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

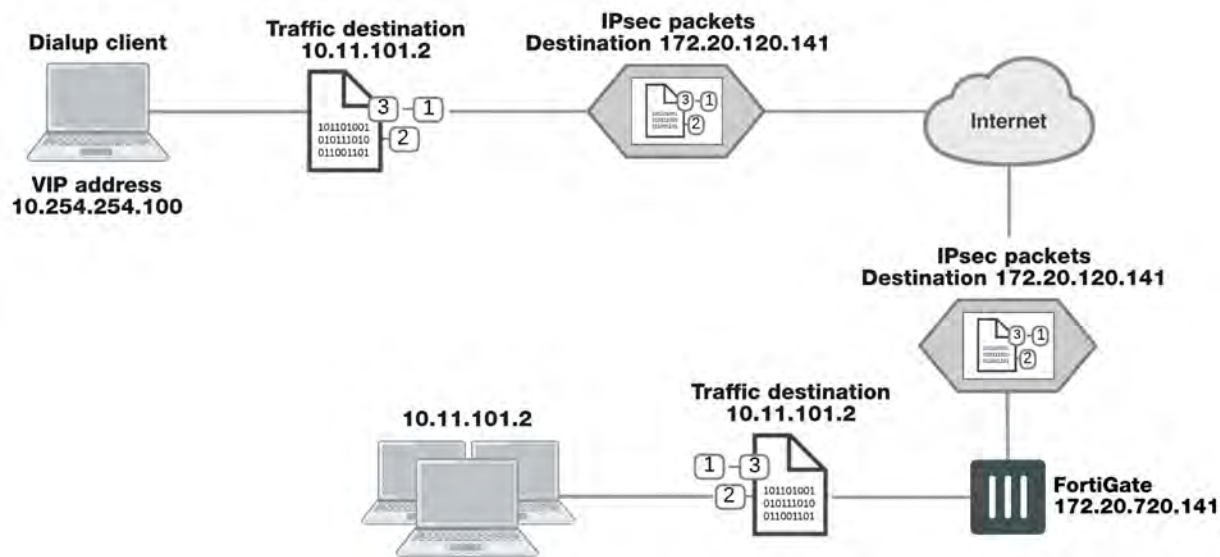

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a Phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see [Phase 2 parameters on page 2067](#).

FortiGate units fully support [RFC 3456](#). The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

The figure below shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

IP address assignments in a FortiClient dialup-client configuration

Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See [RFC 2865](#) and [RFC 2866](#) for more information about RADIUS fields.) To do this:

- Set the DHCP server **IP Assignment Mode** to **User-group defined method**. This is an Advanced setting. See [Configuring a DHCP server on a FortiGate interface on page 2131](#).
- Create a new firewall user group and add the RADIUS server to it.
- In your Phase 1 settings, configure the FortiGate unit as an XAuth server and select from **User Group** the new user group that you created. For more information, see [Phase 1 parameters on page 2048](#).
- Configure the FortiClient application to use XAuth. See [Configuration overview on page 2124](#).

FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.
- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

Configuring the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

- Configure the VPN settings
- If the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
- If the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

The IPsec VPN Wizard greatly simplifies IPsec VPN tunnel creation for route-based tunnels.

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- Configure the FortiGate Phase 1 VPN settings
- Configure the FortiGate Phase 2 VPN settings
- Add the security policy

On the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the FortiClient peer. See [Phase 1 parameters on page 2048](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select Dialup User .
IP Address	Enter the IP address of the remote peer.
Interface	Select the interface through which clients connect to the FortiGate unit.
Mode Config	When enabled, further options become available: <ul style="list-style-type: none"> • Client Address Range • Subnet Mask • Use System DNS • DNS Server • Enable IPv4 Split Tunnel
Authentication Method	Select Pre-shared Key .
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer option	Select Any peer ID .

4. Edit **Authentication** and enter the following information:

Method	Select Pre-shared Key .
---------------	--------------------------------

Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer Options	Set Accept Types to Any peer ID .

- Define the Phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See [Phase 2 parameters on page 2067](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.
Advanced	Select to configure the following optional setting.
DHCP-IPsec	Select if you provide virtual IP addresses to clients using DHCP.

- Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see [Defining policy addresses on page 1](#).

Enter these settings in particular:

- Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
 - If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.
- Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step " Configuration overview " on page 2124.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select all .

Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined in Step "Configuration overview" on page 2124 for the private network behind this FortiGate unit.
Destination Address	If FortiClient users are assigned VIPs, select the address name that you defined for the VIP subnet. Otherwise, select all .
Action	Select IPsec . Under VPN Tunnel , select the name of the Phase 1 configuration that you created in Step "Configuration overview" on page 2124 from the drop-down list. Select Allow traffic to be initiated from the remote site .

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1. Create user accounts for FortiClient users.
2. Create a user group for FortiClient users and the user accounts that you created in step 1.
3. Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
  edit <policy_name>
    set phase2name <tunnel_name>
    set usergroupname <group_name>
    set status enable
  end
```

<tunnel_name> must be the Name you specified in the step 2 of [Configuring the FortiGate unit on page 2127](#). <group_name> must be the name of the user group your created for FortiClient users.

Configuring DHCP services on a FortiGate interface

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- Relay DHCP requests to a DHCP server behind the FortiGate unit (see [Configuring DHCP relay on a FortiGate interface on page 2131](#) below).
- Act as a DHCP server (see [Configuring a DHCP server on a FortiGate interface on page 2131](#)).

Note that DHCP services are typically configured during the interface creation stage, but you can return to an interface to modify DHCP settings if need be.

Configuring DHCP relay on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to relay DHCP.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Open the **Advanced...** menu and set **Mode** to **Relay**.
4. Enter the **DHCP Server IP**.
5. Select **OK**.

Configuring a DHCP server on a FortiGate interface

1. Go to **Network > Interfaces** and select the interface that you want to act as a DHCP server.
2. Enable **DHCP Server**, and create a new DHCP **Address Range** and **Netmask**.
3. Set **Default Gateway** to **Specify**, and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
4. Set **DNS Server** to **Same as System DNS**. If you want to use a different DNS server for VPN clients, select **Specify** and enter an IP address in the available field.
5. Open the **Advanced...** menu and set **Mode** to **Server**.
6. Select **OK**.

Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually. These procedures are based on FortiClient 5.4.1.

Configuring FortiClient

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the FortiClient Administration Guide.

1. Go to **Remote Access** and select the **Settings** icon.
2. Select **Add a new connection**, set the new VPN connection to **IPsec VPN**, and complete following information:

Connection Name	Enter a descriptive name for the connection.
Remote Gateway	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
Authentication Method	Select Pre-shared Key and enter the pre-shared key in the field provided.
Authentication (XAuth)	<p>Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.</p> <p>Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application.</p>

3. Select **OK**.

Adding XAuth authentication

For information about configuring a FortiGate unit as an XAuth server, see [Phase 1 parameters on page 2048](#). The following procedure explains how to configure the FortiClient application.

Note that XAuth is not compatible with IKE version 2.

FortiGate dialup-client configurations

This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

The following topics are included in this section:

Configuration overview

A dialup client can be a FortiGate unit. The FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

Example FortiGate dialup-client configuration

In a dialup-client configuration, the FortiGate dialup server does not rely on a Phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID or peer ID) to each FortiGate dialup client. For more information, see [Phase 1 parameters on page 2048](#).

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see [Phase 1 parameters on page 2048](#).

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see [Phase 1 parameters on page 2048](#).

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

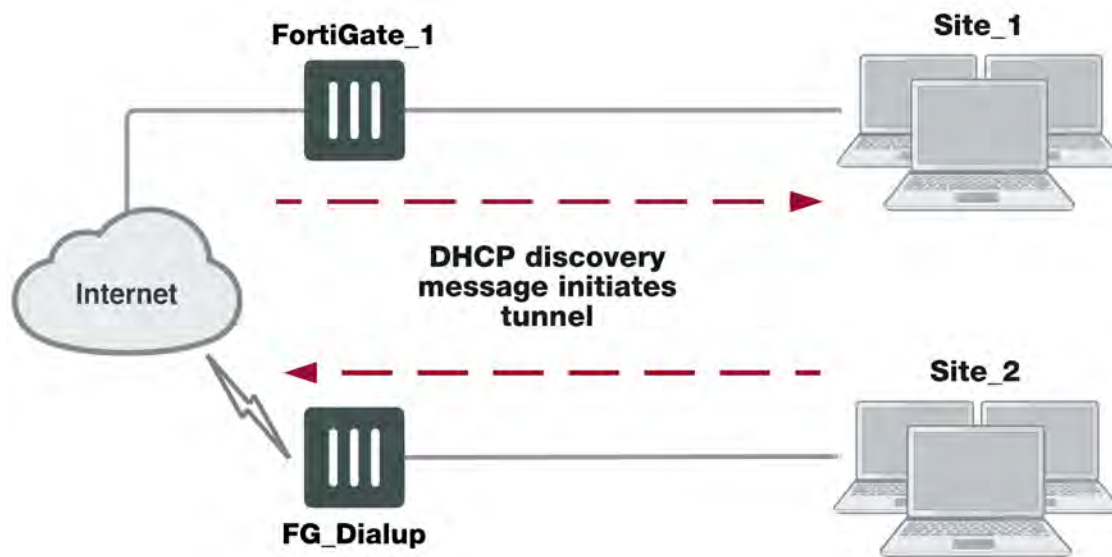

In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server. You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

Preventing network overlap in a FortiGate dialup-client configuration

When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server; its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See [Routing on page 1](#).

FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.
- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
 - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
 - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

Configuring the server to accept FortiGate dialup-client connections

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see [To configure DHCP relay on a FortiGate interface on page 1](#).

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier's documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See [Configuration overview on page 2133](#).
- Configure the FortiGate dialup client. See [Configuration overview on page 2133](#).

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec Phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

In circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.

At the FortiGate dialup server, define the Phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See [Phase 1 parameters on page 2048](#).

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
3. Enter these settings in particular:

Remote Gateway	Select Dialup User .
Interface	Select the interface through which clients connect to the FortiGate unit.

4. Edit **Authentication** and enter the following information:

Mode	If you will be assigning an ID to the FortiGate dialup client, select Aggressive .
Peer Options	If you will be assigning an ID to the FortiGate dialup client, set Accept Types to This peer ID and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.

5. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See [Phase 2 parameters on page 2067](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

- Define names for the addresses or address ranges of the private networks that the VPN links. See [Defining policy addresses on page 1](#). Enter these settings in particular:
 - Define an address name for the server, host, or network behind the FortiGate dialup server.
 - Define an address name for the private network behind the FortiGate dialup client.
- Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.

Destination Address	Select the address name that you defined.
Action	Select IPsec . Under VPN Tunnel , select the name of the Phase 1 configuration that you created in Step "Configuration overview " on page 2133 from the drop-down list. Select Allow traffic to be initiated from the remote site .

- To prevent traffic from the local network from initiating the tunnel after the tunnel has been established, you need to disable the outbound VPN traffic in the CLI

```
config firewall policy
  edit <policy_number>
    set outbound disable
end
```

Place the policy in the policy list above any other policies having similar source and destination addresses.

If configuring a route-based policy, configure a default route for VPN traffic on this interface.

Configuring the FortiGate dialup client

At the FortiGate dialup client, define the Phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See [Phase 1 parameters on page 2048](#).

- Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
- Edit **Network** (full configuration options are only available once you click the **Convert To Custom Tunnel** button).
- Enter these settings in particular:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the dialup server's public interface.
Interface	Select the interface that connects to the public network.
Mode	The FortiGate dialup client has a dynamic IP address, select Aggressive .
Advanced	Select to view the following options.
Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

- Edit **Authentication** and enter the following information:

Mode	The FortiGate dialup client has a dynamic IP address, select Aggressive .
-------------	--

- Edit **Phase 1 Proposal** and enter the following information:

Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.
-----------------	--

- Define the Phase 2 parameters needed to create a VPN tunnel with the dialup server. See [Phase 2 parameters on page 2067](#). Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

- Define names for the addresses or address ranges of the private networks that the VPN links. See [Defining policy addresses on page 1](#). Enter these settings in particular:
 - Define an address name for the server, host, or network behind the FortiGate dialup server.
 - Define an address name for the private network behind the FortiGate dialup client.
- Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [Defining VPN security policies on page 1](#).

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Name	Enter an appropriate name for the policy.
Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Source	Select all .
Destination Address	Select all .
Action	Select ACCEPT .
NAT	Disable NAT .

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

- Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
- Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Source	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind the dialup server.
Action	<p>Select IPsec. Under VPN Tunnel, select the name of the Phase 1 configuration that you created in Step "Configuration overview " on page 2133 from the drop-down list.</p> <p>Clear Allow traffic to be initiated from the remote site to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established.</p>

Place the policy in the policy list above any other policies having similar source and destination addresses.

IPsec dial-up interface sharing

It is possible to use a single interface for all instances that spawn via a given phase1. In this case, instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

The CLI option `"net-device [enable|disable]"` is available in the phase1-interface command sets. Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, the CLI option `"tunnel-search"` is provided. The option is only available when the above `"net-device"` option is `"disable"`.

There are two options for `"tunnel-search"`, corresponding to the two ways to select the tunnel for outbound traffic. One is `"selectors"`, meaning selecting a peer using the IPsec selectors (proxy-ids). The other is `"nexthop"` where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc to resolve the routing. The default for `"tunnel-search"` is `"selectors"`.

Syntax

```
config vpn ipsec phase1-interface
    edit xxx
        set net-device [enable|disable] Enable to create a kernel device for every dialup instance
    next
end
config vpn ipsec phase1-interface
    edit xxx
        set net-device disable
        set tunnel-search [selectors|nexthop] Search for tunnel in selectors or using nexthops
    next
end
```

Supporting IKE Mode Config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see [FortiClient dialup-client configurations on page 1](#).
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document [draft-dukes-ike-mode-cfg-02.txt](#).

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

IKE Mode Config method

IKE Mode Config is configured with the CLI command `config vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

Creating an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax <code>ike-version 2</code> .
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type {ddns static}</code>	If you set <code>type</code> to <code>dynamic</code> , an IKE Mode Config server is created.
<code>assign-ip {enable disable}</code>	Enable to request an IP address from the server.
<code>interface <interface_name></code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
<code>proposal <encryption_combination></code>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see Phase 1 parameters on page 2048 .
<code>ip-version <4 6></code>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to <code>6</code> to create a VPN with IPv6 addressing.

IKE Mode Config client example - CLI

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
  edit vpn1
    set ip-version 4
    set type static
    set remote-gw <gw_address>
    set interface port 1
    set proposal 3des-sha1 aes128-sha1
    set mode-cfg enable
    set assign-ip enable
  end
```

Creating an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax <code>ike-version 2</code> .
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type dynamic</code>	Any other setting creates an IKE Mode Config client.
<code>interface <interface_name></code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
<code>proposal <encryption_combination></code>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see Phase 1 parameters on page 2048 .
<code>ip-version <4 6></code>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to <code>6</code> to create a VPN with IPv6 addressing.

IKE Mode Config server example - CLI

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

When IKE Mode-Configuration is enabled, multiple server IPs can be defined in IPsec Phase 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the FortiGate CLI Reference.

```
config vpn ipsec phase1-interface
edit "vpn-p1"
    set type dynamic
    set interface "wan1"
    set xauthtype auto
    set mode aggressive
    set mode-cfg enable
    set proposal 3des-sha1 aes128-sha1
    set dpd disable
    set dhgrp 2
    set xauthexpire on-rekey
    set authusrgrp "FG-Group1"
    set ipv4-start-ip 10.10.10.10
    set ipv4-end-ip 10.10.10.20
    set ipv4-dns-server1 1.1.1.1
    set ipv4-dns-server2 2.2.2.2
    set ipv4-dns-server3 3.3.3.3
    set ipv4-wins-server1 4.4.4.4
    set ipv4-wins-server2 5.5.5.5
```

```
set domain "fgt1c-domain"
set banner "fgt111C-banner"
set backup-gateway "100.100.100.1" "host1.com" "host2"
set ipv4-split-include OfficeLAN
end
```

IP address assignment

After you have enabled the basic configuration, you can configure IP address assignment for clients, as well as DNS and WINS server assignment. Usually you will want to assign IP addresses to clients.

The simplest method to assign IP addresses to clients is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user's IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

IKE Mode Config can also use a remote DHCP server to assign the client IP addresses. Up to eight addresses can be selected for either IPv4 or IPv6. After the DHCP proxy has been configured, the `assign-ip-from` command is used to assign IP addresses via DHCP.

Assigning IP addresses from an address range - CLI

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
set mode-cfg-ipversion 4
set assign-ip enable
set assign-ip-type ip
set assign-ip-from range
set ipv4-start-ip <range_start>
set ipv4-end-ip <range_end>
set ipv4-netmask <netmask>
end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
set mode-cfg-ipversion 6
set assign-ip enable
set assign-ip-type ip
set assign-ip-from range
set ipv6-start-ip <range_start>
set ipv6-end-ip <range_end>
end
```

Assigning IP addresses from a RADIUS server - CLI

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group `<grpname>`. Since the IP address will not be static, `type` is set to `dynamic`, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
```

```
edit vpn1
  set type dynamic
  set mode-cfg enable
  set assign-ip enable
  set assign-ip-from usrgrp
  set xauthtype auto
  set authusrgrp <grpname>
end
```

Assigning IP address from DHCP - CLI

The DHCP proxy must first be enabled for IKE Mode Config to use DHCP to assign the VPN client IP address(es).

```
config system settings
  set dhcp-proxy enable
  set dhcp-server-ip [ipv4 address]
  set dhcp6-server-ip [ipv6-address]
```

(Up to eight server addresses can be configured)

```
end

config vpn ipsec phase1-interface
  edit vpn1
    set mode-cfg enable
    set assign-ip-from dhcp
  next
end
```

Assigning IP address from a named firewall address/group - CLI

```
config vpn ipsec phase1-interface
  edit <name>vpn1
    set type dynamic
    set assign-ip-from name
    set ipv4-name <name>
    set ipv6-name <name>
  next
end
```

Certificate groups

IKE certificate groups consisting of up to four RSA certificates can be used in IKE Phase 1. Since CA and local certificates are global, the IKE daemon loads them once for all VDOMs and indexes them into trees based on subject and public key hash (for CA certificates), or certificate name (for local certificates). Certificates are linked together based on the issuer, and certificate chains are built by traversing these links. This reduces the need to keep multiple copies of certificates that could exist in multiple chains.

IKE certificate groups can be configured through the CLI.

Configuring the IKE local ID - CLI

```
config vpn certificate local
  edit <name>
    set ike-localid <string>
    set ike-localid-type {asn1dn | fqdn}
  end
```

Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

The following topics are included in this section:

Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In the figure below, FortiGate_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup_1 and users on the Site_2 network behind FortiGate_2, which could be a VPN peer or a dialup client.

Example Internet-browsing configuration

You can adapt any of the following configurations to provide secure Internet browsing:

- A gateway-to-gateway configuration (see [Gateway-to-gateway configurations on page 1](#))
- A FortiClient dialup-client configuration (see [FortiClient dialup-client configurations on page 1](#))
- A FortiGate dialup-client configuration (see [FortiGate dialup-client configurations on page 1](#))

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See [Configuration overview on page 2146](#), below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See [Configuration overview on page 2146](#).

Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

Creating an Internet browsing policy - policy-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The interface to which the VPN tunnel is bound.
Outgoing Interface	The interface to which the VPN tunnel is bound.
Source	The internal range address of the remote spoke site.
Destination Address	all
Action	Select IPsec . Under VPN Tunnel , select the tunnel that provides access to the private network behind the FortiGate unit. Select Allow traffic to be initiated from the remote site .
NAT	Enable NAT .

Creating an Internet browsing policy - route-based VPN

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and then select **OK**:

Name	Enter an appropriate name for the policy.
Incoming Interface	The IPsec VPN interface.

Outgoing Interface	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
Source	The internal range address of the remote spoke site.
Destination Address	all
Action	ACCEPT
NAT	Enable NAT .

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration, or a FortiClient application that protects an individual client PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see [Configuring a FortiGate remote peer to support Internet browsing on page 2148](#).
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see [Configuring a FortiClient application to support Internet browsing on page 2149](#).

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in [Configuration overview on page 2146](#).

Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

Routing all traffic through a policy-based VPN

1. At the FortiGate dialup client, go to **Policy & Objects > IPv4 Policy**.
2. Select the IPsec security policy and then select **Edit**.
3. From the **Destination Address** list, select **all**.
4. Select **OK**.

Packets are routed through the VPN tunnel, not just those destined for the protected private network.

Routing all traffic through a route-based VPN

1. At the FortiGate dialup client, go to **Network > Static Routes**.
2. Select the default route (destination IP 0.0.0.0) and then select **Edit**. If there is no default route, select **Create New**. Enter the following information and select **OK**:

Destination IP/Mask	Set to Subnet and enter 0.0.0.0/0.0.0.0 in the field provided.
----------------------------	--

Device	Select the IPsec virtual interface.
Administrative Distance	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

Routing all traffic through VPN - FortiClient application

1. At the remote host, start FortiClient.
2. Go to **Remote Access**.
3. Select the definition that connects FortiClient to the FortiGate dialup server, select the **Settings** icon, and select **Edit the selected connection**.
4. In the **Edit VPN Connection** dialog box, select **Advanced Settings**.
5. In the **Remote Network** group, select **Add**.
6. In the **IP** and **Subnet Mask** fields, type `0.0.0.0/0.0.0.0` and select **OK**.

The address is added to the **Remote Network** list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.

7. Select **OK**.

Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode or manual keys. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. The figure below shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see [Configuration overview on page 2150](#). This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see [Configuration overview on page 2150](#).

Example redundant-tunnel configuration

A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

General configuration steps

A redundant configuration at each VPN peer includes:

- One Phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- One Phase 2 definition for each Phase 1 configuration.
- One static route for each IPsec interface, with different distance values to prioritize the routes.
- Two Accept security policies per IPsec interface, one for each direction of traffic.
- Dead peer detection enabled in each Phase 1 definition.

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

Configuring the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1. Ensure that the interfaces used in the VPN have static IP addresses.
2. Create a Phase 1 configuration for each of the paths between the peers.
3. Enable dead peer detection so that one of the other paths is activated if this path fails.
4. Enter these settings in particular, and any other VPN settings as required:

Path 1

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 2

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 3

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

Path 4

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

For more information, see [Phase 1 parameters on page 2048](#).

5. Create a Phase 2 definition for each path. See [Phase 2 parameters on page 2067](#). Select the Phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.
6. Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

Destination IP/Mask	The IP address and netmask of the private network behind the remote peer.
Device	One of the virtual IPsec interfaces on the local peer.
Distance	For each path, enter a different value to prioritize the paths.

7. Define the security policy for the local primary interface. See [Defining VPN security policies on page 1](#). You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	All
Outgoing Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

8. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Source Address	All
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

9. Place the policy in the policy list above any other policies having similar source and destination addresses.
10. Repeat this procedure at the remote FortiGate unit.

Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The `monitor` option creates a backup VPN for the specified Phase 1 configuration.

In the following example, `backup_vpn` is a backup for `main_vpn`.

```
config vpn ipsec phase1-interface
  edit main_vpn
    set dpd on
    set interface port1
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
  edit backup_vpn
    set dpd on
    set interface port2
    set monitor main_vpn
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
end
```

Transparent mode VPNs

This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

The following topics are included in this section:

Configuration overview

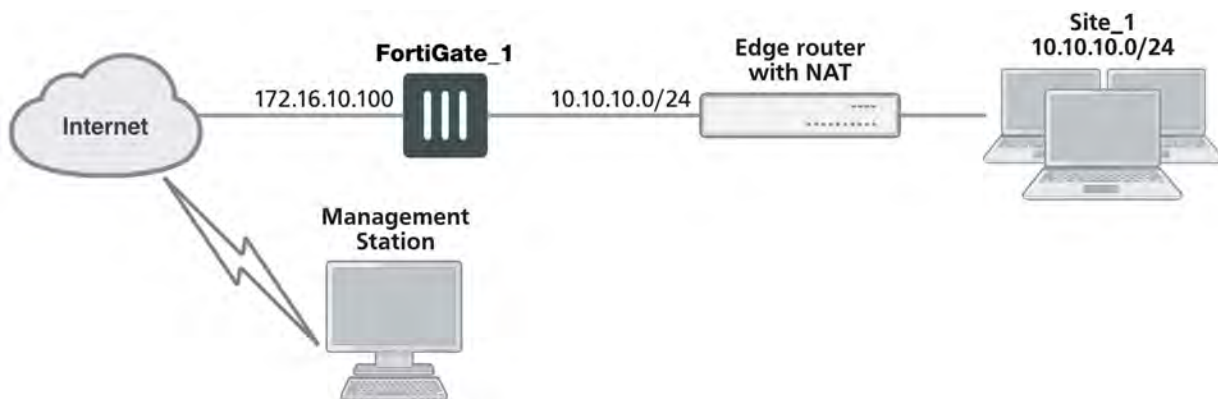

In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. The figure below shows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

Management station on internal network

An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see the figure below), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

Management station on external network

In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the Advanced Routing Guide.

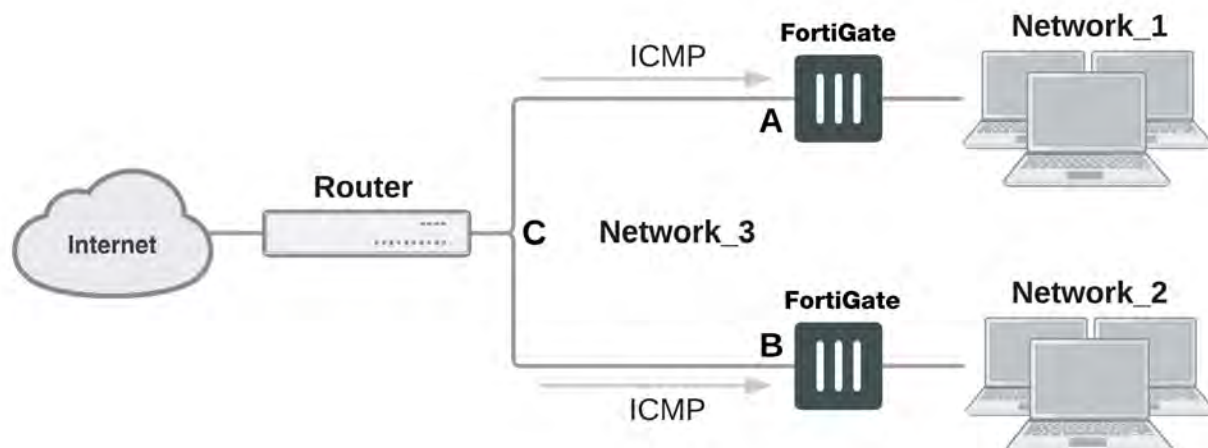

In the example configuration shown above, Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see the figure below), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (as shown in the following figure).

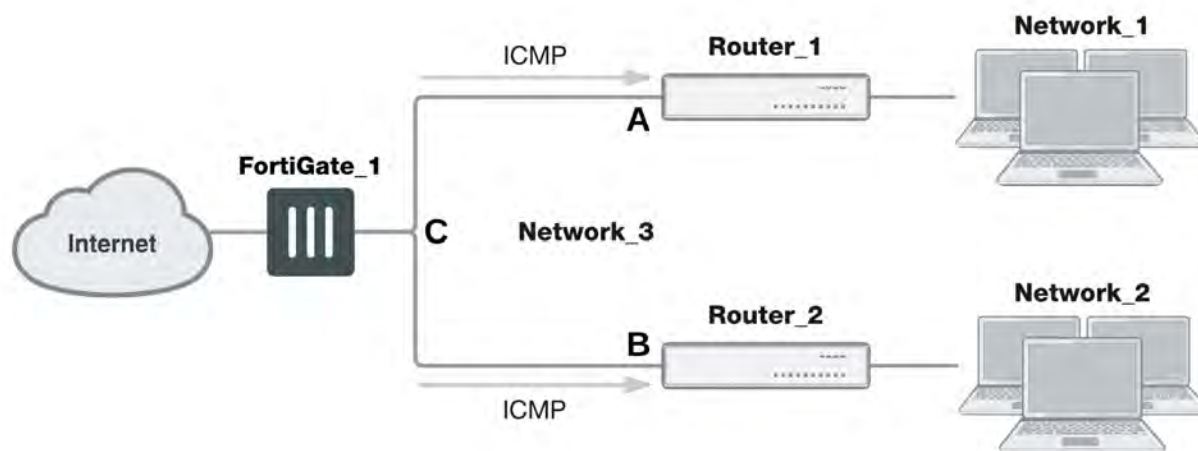

Link between two FortiGate units in transparent mode

In the figure below, interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network_1 to interface A and redirect packets destined for Network_2 to interface B.

ICMP redirecting packets to two FortiGate units in transparent mode

If there are additional routers behind the FortiGate unit (see the figure below) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in the following figure, the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network_1 and Network_2 respectively.

Destinations on remote networks behind internal routers**Transparent VPN infrastructure requirements**

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components.

Configuring the VPN peers

1. The local VPN peer need to operate in transparent mode.

To determine if your FortiGate unit is in transparent mode, go to the **Dashboard > System Information** widget. Select **[change]**. Select transparent for the **Operation Mode**. Two new fields will appear to enter the **Management IP/Netmask**, and the **Default Gateway**.

In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

The remote VPN peer may operate in NAT mode or transparent mode.

2. At the local FortiGate unit, define the Phase 1 parameters needed to establish a secure connection with the remote peer. See [Phase 1 parameters on page 2048](#). Select **Advanced** and enter these settings in particular:

Remote Gateway	Select Static IP Address .
IP Address	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
Advanced	Select Nat-traversal , and type a value into the Keepalive Frequency field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see Phase 1 parameters on page 2048 and Phase 1 parameters on page 2048 .

3. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See [Phase 2 parameters on page 2067](#). Select the set of Phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the **Static IP Address** list.
4. Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

- For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. For the management interface, for example, 10.10.10.0/24. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select **any** for this address.
 - For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, 192.168.10.0/24). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.
5. Define an IPsec security policy to permit communications between the source and destination addresses. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 4.
Outgoing Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Destination Address	Select the destination address that you defined in Step 4.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

6. Place the policy in the policy list above any other policies having similar source and destination addresses.
7. Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See [Defining VPN security policies on page 1](#). Enter these settings in particular:

Incoming Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Source Address	Select the destination address that you defined in Step 4..
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 4.
VPN Tunnel	<p>Select Use Existing and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list.</p> <p>Select Allow traffic to be initiated from the remote site to enable traffic from the remote network to initiate the tunnel.</p>

8. Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Visibility**.
2. Enable **IPv6**.
3. Select **Apply**.

The following topics are included in this section:

IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 4.0 MR3 is IPv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The Phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The Phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 Phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuration examples

This section consists of the following configuration examples:

- [Site-to-site IPv6 over IPv6 VPN example](#)
- [Site-to-site IPv6 over IPv4 VPN example](#)
- [Site-to-site IPv4 over IPv6 VPN example](#)

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

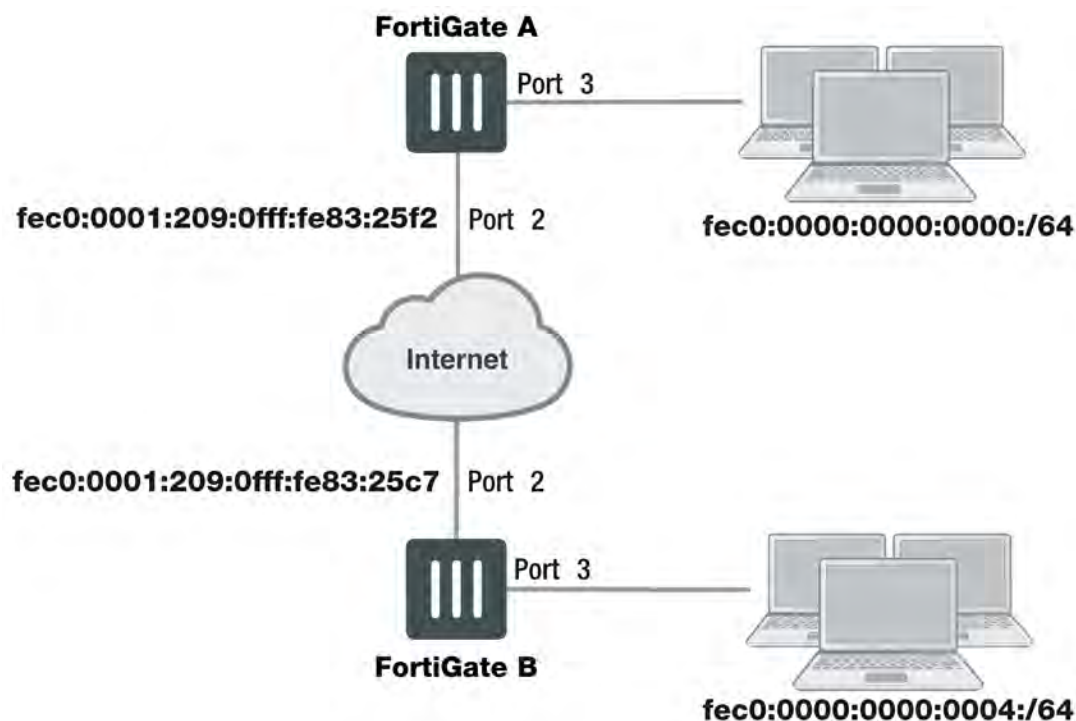

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Feature Visibility**.
2. Enable **IPv6**.
3. Select **Apply**.

Example IPv6-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
```

```

edit port2
  config ipv6
    set ip6-address fec0::0001:209:0fff:fe83:25f2/64
  end
next
edit port3
  config ipv6
    set ip6-address fec0::0000:209:0fff:fe83:25f3/64
  end
next
end

```

Configure FortiGate A IPsec settings

The Phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```

config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end

```

By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```

config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end

```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```

config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ALL
    set schedule always
  next

```

```
edit 2
  set srcintf toB
  set dstintf port3
  set srcaddr all6
  set dstaddr all6
  set action accept
  set service ALL
  set schedule always
end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  end
end
```

Configure FortiGate B

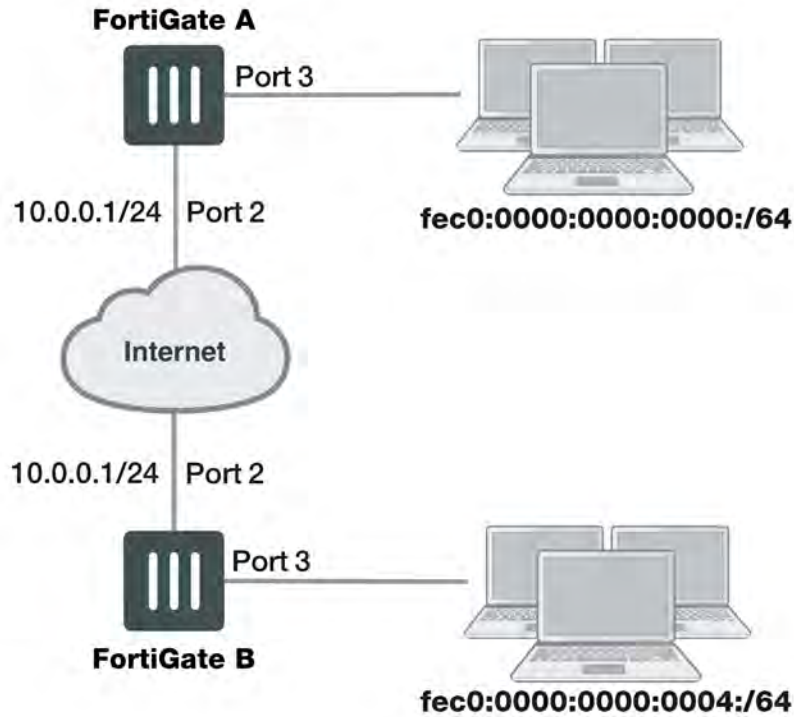

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:209:0fff:fe83:25c7/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
  end
end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
  end
end
```

```
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end
config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ALL
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ALL
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology**Configure FortiGate A interfaces**

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
  end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
    set interface port2
    set remote-gw 10.0.1.1
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The Phase 2 configuration uses IPv6 selectors. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
edit toB2
set phase1name toB
set proposal 3des-md5 3des-sha1
set pfs enable
set replay enable
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between `port3` and the IPsec interface `toB` in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
edit 1
set srcintf port3
set dstintf toB
set srcaddr all6
set dstaddr all6
set action accept
set service ALL
set schedule always
next
edit 2
set srcintf toB
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ALL
set schedule always
end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface `toB` using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on `port2`.

```
config router static6
edit 1
set device toB
set dst fec0:0000:0000:0004::/64
end
config router static
edit 1
set device port2
set dst 0.0.0.0/0
set gateway 10.0.0.254
end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
  edit port2
    set 10.0.1.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
config vpn ipsec phase1-interface
  edit toA
    set interface port2
    set remote-gw 10.0.0.1
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-shal
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-shal
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ALL
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ALL
    set schedule always
  end
config router static6
  edit 1
    set device toA
```

```

    set dst fec0:0000:0000:0000::/64
end
config router static
edit 1
    set device port2
    set gateway 10.0.1.254
end

```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology

Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```

config system interface
edit port2
    config ipv6
        set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
next
edit port3
    set 192.168.2.1/24
end

```

Configure FortiGate A IPsec settings

The Phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd [disable | on-idle | on-demand]
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
end
```

The Phase 2 configuration is the same as you would use for an IPv4 VPN. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
next
edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
edit 1
    set device port2
    set dst 0::/0
next
edit 2
```

```

    set device toB
    set dst 192.168.3.0/24
end

```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:fe83:25c7/64
        end
    next
    edit port3
        set 192.168.3.1/24
    end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd [disable | on-idle | on-demand]
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
config vpn ipsec phase2-interface
    edit toA2
        set phase1name toA
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
    end
config firewall policy
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all
        set dstaddr all
        set action accept
        set service ALL
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all
        set dstaddr all
        set action accept
        set service ALL
        set schedule always

```

```
end
config router static6
edit 1
    set device port2
    set dst 0::/0
next
edit 2
    set device toA
    set dst 192.168.2.0/24
end
```

L2TP and IPsec (Microsoft VPN)

This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

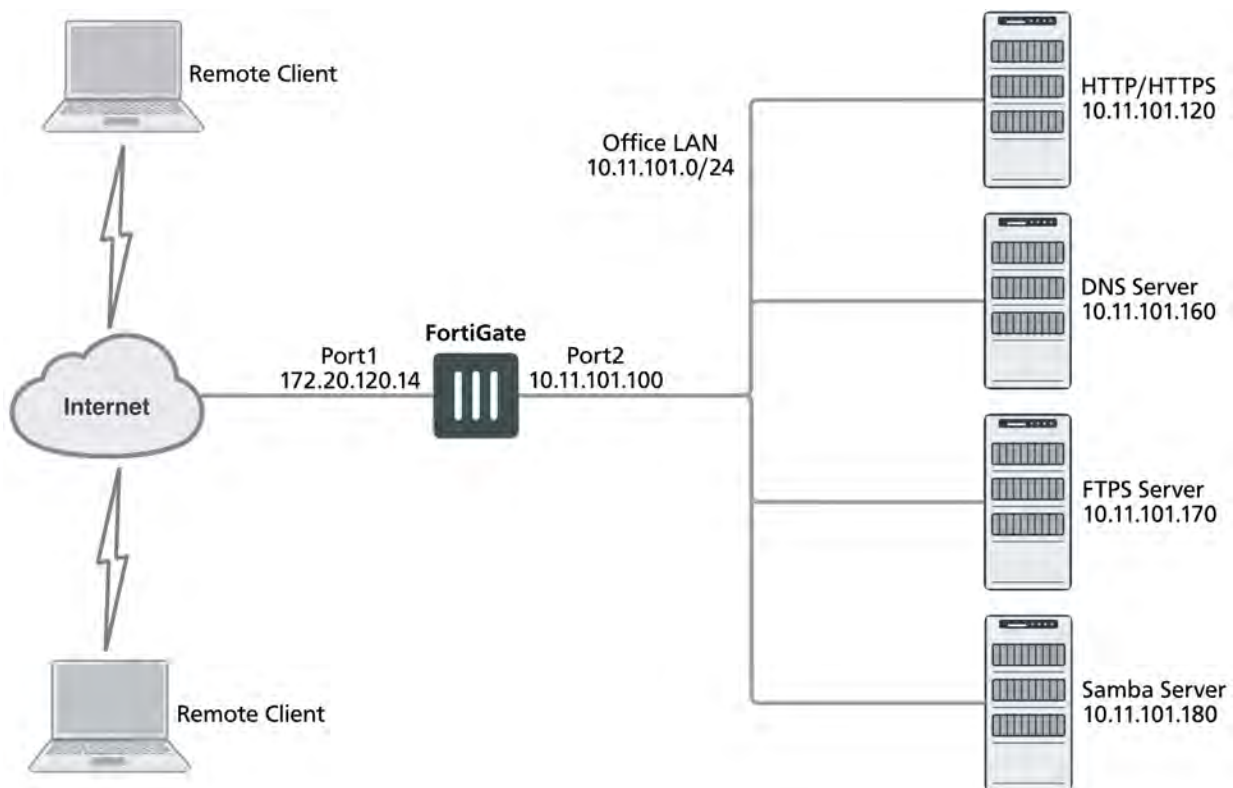

The following topics are included in this section:

For troubleshooting information, refer to [Troubleshooting L2TP and IPsec](#).

Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

Example FortiGate VPN configuration with Microsoft clients

For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. Starting in FortiOS 4.0 MR2, you can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPsec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Windows PC.

Configuring the FortiGate unit

To configure the FortiGate unit, you must:

- Configure L2TP users and firewall user group.
- Configure the L2TP VPN, including the IP address range it assigns to clients.
- Configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client.
- Configure security policies.

Configuring L2TP users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Windows network logon credentials. You might want to use these for their L2TP user name and password.

Creating a user account - web-based manager

1. Go to **User & Device > User Definition** and select **Create New**.
2. Enter the **User Name**.
3. Do one of the following:
 - Select **Password** and enter the user's assigned password.

- Select **Match user on LDAP server**, **Match user on RADIUS server**, or **Match user on TACACS+ server** and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.

4. Select **OK**.

Creating a user account - CLI

To create a user account called `user1` with the password `123_user`, enter:

```
config user local
  edit user1
    set type password
    set passwd "123_user"
    set status enable
  end
```

Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

Creating a user group - web-based manager

1. Go to **User & Device > User Groups**, select **Create New**, and enter the following:

Name	Type or edit the user group name (for example, <code>L2TP_group</code>).
Type	Select Firewall .
Available Users/Groups	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
Members	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2. Select **OK**.

Creating a user group - CLI

To create the user group `L2TP_group` and add members `User_1`, `User_2`, and `User_3`, enter:

```
config user group
  edit L2TP_group
    set group-type firewall
    set member User_1 User_2 User_3
  end
```

Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow access to users in the `L2TP_group` and assign them addresses in the range 192.168.0.50 to 192.168.0.59, enter:

```

config vpn l2tp
  set sip 192.168.0.50
  set eip 192.168.0.59
  set status enable
  set usrgrp "L2TP_group"
end

```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```

config firewall address
  edit L2TPclients
    set type iprange
    set start-ip 192.168.0.50
    set end-ip 192.168.0.59
  end

```

Alternatively, you could define this range in the web-based manager.

Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

Whether Transport mode is *required* depends on the configuration of the peer device (typically an old Windows device, since newer versions of Windows don't require IPsec and L2TP—they can run IPsec natively).

When configuring L2TP, do not name the VPN "L2TP" as that will result in a conflict.

L2TP over IPsec is supported on the FortiGate unit for both policy-based and route-based configurations, but the following example is policy-based.

Configuring Phase 1 - web-based manager

1. Go to **VPN > IPsec Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

Name	Enter a name for this VPN, dialup_p1 for example.
Remote Gateway	Dialup User
Local Interface	Select the network interface that connects to the Internet. For example, port1.
Mode	Main (ID protection)

Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
Advanced	Select Advanced to enter the following information.
Phase 1 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Diffie-Hellman Group	2
NAT Traversal	Enable
Dead Peer Detection	Enable

Configuring Phase 1 - CLI

To create a Phase 1 configuration called dialup_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
  edit dialup_p1
    set type dynamic
    set interface port1
    set mode main
    set psksecret *****
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set dhgrp 2
    set natTraversal enable
    set dpd [disable | on-idle | on-demand]
  end
```

It is worth noting here that the command `config vpn ipsec phase1` is used rather than `config vpn ipsec phase1-interface` because this configuration is policy-based and not route-based.

Configuring Phase 2 - web-based manager

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and then select **OK**.

Phase 2 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Enable replay detection	Enable
Enable perfect forward secrecy (PFS)	Disable
Keylife	3600 seconds

3. Make this a transport-mode VPN. You must use the CLI to do this. If your Phase 2 name is dialup_p2, you would enter:

```
config vpn ipsec phase2
edit dialup_p2
set encapsulation transport-mode
end
```

Configuring Phase 2 - CLI

To configure a Phase 2 to work with your phase_1 configuration, you would enter:

```
config vpn ipsec phase2
edit dialup_p2
set phase1name dialup_p1
set proposal aes256-md5 3des-sha1 aes192-sha1
set replay enable
set pfs disable
set keylifeseconds 3600
set encapsulation transport-mode
end
```

Once again, note here that the command `config vpn ipsec phase2` is used rather than `config vpn ipsec phase2-interface` because this configuration is policy-based and not route-based.

Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- An IPsec policy, as you would create for any policy-based IPsec VPN
- A regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

Configuring the IPsec security policy - web-based manager

1. Go to **System > Feature Visibility** and enable **Policy-based IPsec VPN**.
2. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
3. Set the **Action** to **IPsec** and enter the following information:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	All
VPN Tunnel	Select Use Existing and select the name of the Phase 1 configuration that you created. For example, dialup_p1. See Configuring IPsec on page 2175 .
Allow traffic to be initiated from the remote site	enable

4. Select **OK**.

Configuring the IPsec security policy - CLI

If your VPN tunnel (Phase 1) is called dialup_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
edit 0
set srcintf port2
set dstintf port1
set srcaddr all
set dstaddr all
set action ipsec
set schedule always
set service all
set inbound enable
set vpngroup dialup_p1
end
```

Configuring the ACCEPT security policy - web-based manager

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information and select **OK**:

Incoming Interface	Select the FortiGate unit's public interface.
Source Address	Select the firewall address that you defined for the L2TP clients.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT

Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
edit 1
set srcintf port1
set dstintf port2
set srcaddr L2TPclients
set dstaddr all
set action accept
set schedule always
set service all
end
```

Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

1. In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
2. Ensure that the IPSEC service is running.
3. Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP. Other versions of Windows may vary slightly.

Configuring the network connection

1. Open **Network Connections**.
This is available through the Control Panel.
2. Double-click **New Connection Wizard** and **Select Next**.
3. Select **Connect to the network at my workplace**.
4. Select **Next**.
5. Select **Virtual Private Network connection** and select **Next**.
6. In the **Company Name** field, enter a name for the connection and select **Next**.
7. Select **Do not dial the initial connection** and then select **Next**.
8. Enter the public IP address or FQDN of the FortiGate unit and select **Next**.
9. Optionally, select **Add a shortcut to this connection to my desktop**.
10. Select **Finish**.
The **Connect** dialog opens on the desktop.
11. Select **Properties** and then select the **Security** tab.
12. Select **IPsec Settings**.
13. Select **Use pre-shared key for authentication**, enter the preshared key that you configured for your VPN, and select **OK**.
14. Select **OK**.

Checking that the IPsec service is running

1. Open **Administrative Tools** through the Control Panel.
2. Double-click **Services**.
3. Look for IPSEC Services. Confirm that the **Startup Type** is **Automatic** and **Status** is set to **Started**. If needed, double-click **IPsec Services** to change these settings.

Checking that IPsec has not been disabled

1. Select **Start > Run**.
2. Enter regedit and select **OK**.
3. Find the Registry key HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4. If there is a ProhibitIPsec value, it must be set to 0.

Enforcing IPsec in L2TP configuration

An `enforce-ipsec` option is available in L2TP configuration to force the FortiGate L2TP server to accept only IPsec encrypted connections.

Syntax

```
config vpn l2tp
```

```
set eip 50.0.0.100
set sip 50.0.0.1
set status enable
set enforce-ipsec-interface {disable | enable}      (default = disable)
set usrgrp <group_name>
end
```

GRE over IPsec (Cisco VPN)

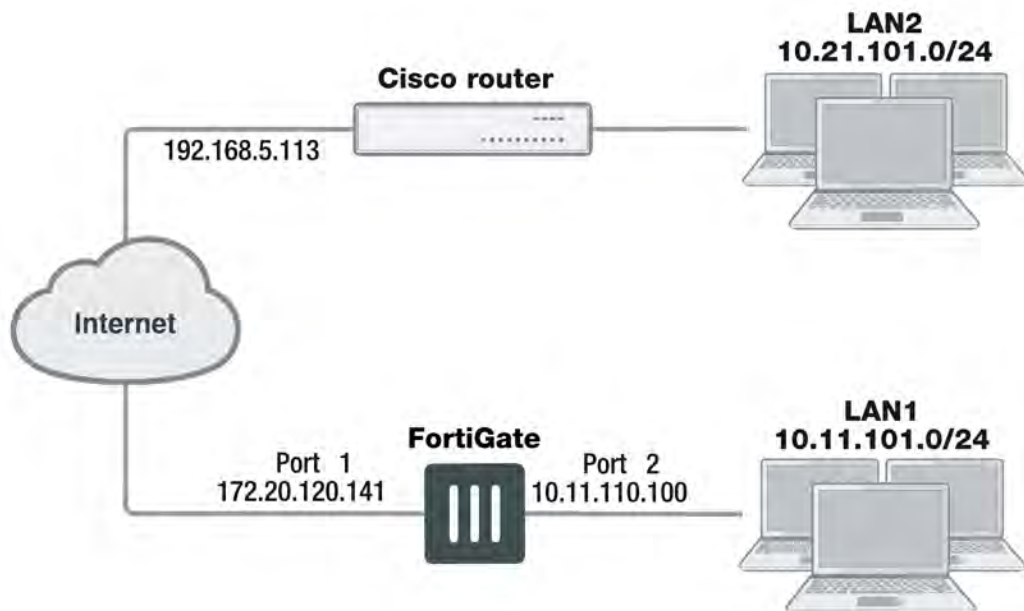

This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

The following topics are included in this section:

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Before FortiOS 4.0 MR2, the FortiGate unit was compatible only with tunnel mode IPsec.

Example FortiGate to Cisco GRE-over-IPsec VPN

In this example, users on LAN1 are provided access to LAN2.

Configuration overview

The following section consists of configuring the FortiGate unit and configuring the Cisco router.

Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.
- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
    set allow-subnet-overlap enable
end
```

Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

Configuring the IPsec VPN - web-based manager

1. Define the Phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tocsico for example. This is the name of the virtual IPsec interface. It appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select Static IP Address .
IP Address	Enter the IP address of the Cisco device public interface. For example, 192.168.5.113.
Local Interface	Select the FortiGate unit's public interface. For example, 172.20.120.141.
Mode	Select Main (ID Protection) .

Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. It must match the preshared key on the Cisco device.
Advanced	Select the Advanced button to see the following settings.
Phase 1 Proposal	3DES-MD5
	At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see [Phase 1 parameters on page 2048](#).

2. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

Phase 2 Proposal	3DES-MD5
	At least one proposal must match the settings on the Cisco unit.
Quick Mode Selector	
Source Address	Enter the GRE local tunnel end IP address. For example 172.20.120.141.
Source Port	0
Destination Address	Enter the GRE remote tunnel end IP address. For example 192.168.5.113.
Destination Port	0
Protocol	47

For more information about these settings, see [Phase 2 parameters on page 2067](#).

3. If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your Phase 2 configuration, set `encapsulation` to `transport-mode` as follows:

```
config vpn phase2-interface
edit to_cisco_p2
set encapsulation transport-mode
end
```

Configuring the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
edit tocisco
set interface port1
set proposal 3des-sha1 aes128-sha1
set remote-gw 192.168.5.113
set psksecret xxxxxxxxxxxxxxxxx
```

```

end
config vpn ipsec phase2-interface
edit tocisco_p2
    set phase1name "tocisco"
    set proposal 3des-md5
    set encapsulation tunnel-mode // if tunnel mode
    set encapsulation transport-mode // if transport mode
    set protocol 47
    set src-addr-type ip
    set dst-start-ip 192.168.5.113
    set src-start-ip 172.20.120.141
end

```

Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```

config system interface
edit tocisco
    set ip 172.20.120.141 255.255.255.255
    set remote-ip 192.168.5.113
end

```

Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```

config system gre-tunnel
edit gre1
    set interface tocisco
    set local-gw 172.20.120.141
    set remote-gw 192.168.5.113
end

```

`interface` is the virtual IPsec interface, `local-gw` is the FortiGate unit public IP address, and `remote-gw` is the remote Cisco device public IP address

Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```

config system interface
edit gre1
    set ip 10.0.1.1 255.255.255.255
    set remote-ip 10.0.1.2
end

```

Configuring security policies

Two sets of security policies are required:

- Policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

Configuring security policies - web-based manager

1. Define an ACCEPT firewall security policy to permit communications between the protected network and the GRE tunnel:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the GRE tunnel virtual interface you configured.
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

2. To permit the remote client to initiate communication, you need to define a firewall address security policy for communication in that direction:

Incoming Interface	Select the GRE tunnel virtual interface you configured.
Source Address	All
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

3. Define a pair of ACCEPT firewall address security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

Incoming Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 2184 .
Source Address	All
Outgoing Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 2182 .
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

Incoming Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 2182 .
Source Address	All
Outgoing Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 2184 .
Destination Address	All
Action	ACCEPT
Enable NAT	Disable

Configuring security policies - CLI

```

config firewall policy
  edit 1 // LAN to GRE tunnel
    set srcintf port2
    set dstintf gre1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
  next
  edit 2 // GRE tunnel to LAN
    set srcintf gre1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
  next
  edit 3 // GRE tunnel to IPsec interface
    set srcintf "gre1"
    set dstintf "tocisco"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
  next
  edit 4 // IPsec interface to GRE tunnel
    set srcintf "tocisco"
    set dstintf "gre1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
end

```

Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0.
Device	Select the GRE virtual interface.
Distance (Advanced)	Leave setting at default value.

In the CLI, using the example values, you would enter

```
config router static
edit 0
set device gre1
set dst 10.21.101.0 255.255.255.0
end
```

Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnel1
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnel1
end
clea crypto sa
clea crypto isakmp
```

For transport mode, change `no mode` to `mode transport`.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

Keep-alive support for GRE

The FortiGate can send a GRE keep-alive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Syntax

```
config system gre-tunnel
  edit <id>
    set keepalive-interval <value: 0-32767>
    set keepalive-failtimes <value: 1-255>
  next
end
```

Protecting OSPF with IPsec

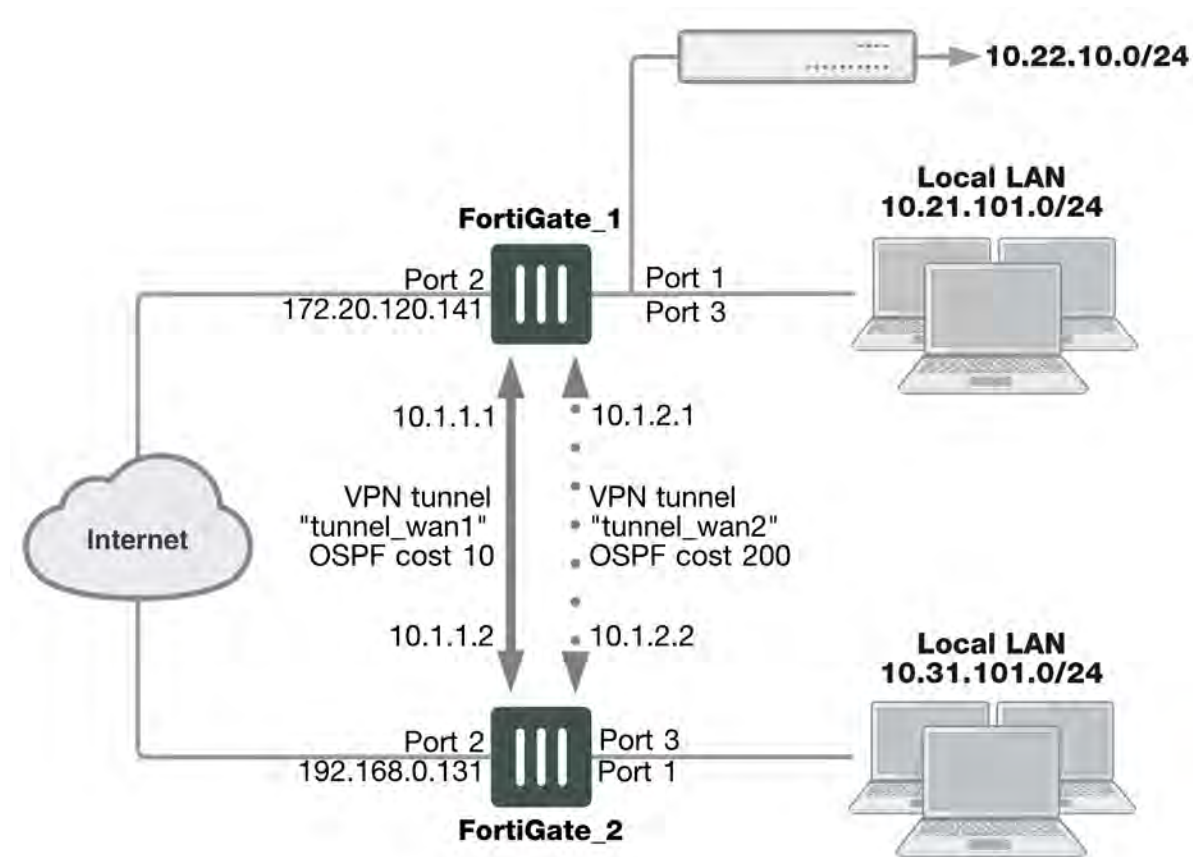

For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

The following topics are included in this section:

Configuration overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown below is a single OSPF area. FortiGate_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate_2 advertises its local LAN as an OSPF internal route.

OSPF over an IPsec VPN tunnel

The section [Configuration overview](#) describes the configuration with only one IPsec VPN tunnel, tunnel_wan1. Then, the section [Configuration overview](#) describes how you can add a second tunnel to provide a redundant backup path. This is shown above as VPN tunnel "tunnel_wan2".

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.
- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel_wan1. The other VPN is added in the section [Configuration overview on page 2189](#).

Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

Configuring Phase 1

1. Define the Phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see [Phase 1 parameters on page 2048](#).

Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
Remote Gateway	Select Static IP Address .
IP Address	Enter the IP address of the other FortiGate unit's public (Port 2) interface.
Local Interface	Select this FortiGate unit's public (Port 2) interface.
Mode	Select Main (ID Protection) .
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
Advanced	Select Advanced .

Assigning the tunnel end IP addresses

1. Go to **Network > Interfaces**, select the virtual IPsec interface that you just created on Port 2 and select **Edit**.
2. In the **IP** and **Remote IP** fields, enter the following tunnel end addresses:

	FortiGate_1	FortiGate_2
IP	10.1.1.1	10.1.1.2
Remote_IP	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

Configuring Phase 2

1. Enter a name to identify this Phase 2 configuration, `twan1_p2`, for example.
2. Select the name of the Phase 1 configuration that you defined in Step ["Configuration overview" on page 2189](#), `tunnel_wan1` for example.

Configuring static routing

You need to define the route for traffic leaving the external interface.

1. Go to **Network > Static Routes**, select **Create New**.
2. Enter the following information.

Destination IP/Mask	Leave as 0.0.0.0 0.0.0.0.
Device	Select the external interface.
Gateway	Enter the IP address of the next hop router.

Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address. The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate_1 is an AS border router that advertises its static default route. FortiGate_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

FortiGate_1 OSPF configuration

When configuring FortiGate_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
```

```

edit lback1
  set vdom root
  set ip 10.0.0.1 255.255.255.255
  set type loopback
end

```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area, networks, and interfaces - web-based manager

1. On FortiGate_1, go to **Network > OSPF**.
2. Enter the following information to define the router, area, and interface information.

Router ID	Enter 10.0.0.1. Select Apply before entering the remaining information.
Advanced Options	
Redistribute	Select the Connected and Static check boxes. Use their default metric values.
Areas	Select Create New , enter the Area and Type and then select OK .
Area	0.0.0.0
Type	Regular
Interfaces	Enter a name for the OSPF interface, ospf_wan1 for example.
Name	
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the **IP/Netmask** of 10.1.1.0/255.255.255.0 and an **Area** of 0.0.0.0.
5. For **Networks**, select **Create New**.
6. Enter the **IP/Netmask** of 10.0.0.1/255.255.255.0 and an **Area** of 0.0.0.0.
7. Select **Apply**.

Configuring OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named tunnel_wan1. Enter the following CLI commands:

```

config router ospf
  set router-id 10.0.0.1
  config area
    edit 0.0.0.0
  end
  config network
    edit 4
  end
end

```

```
        set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
        set prefix 10.0.0.1 255.255.255.255
    end
    config ospf-interface
        edit ospf_wan1
            set cost 10
            set interface tunnel_wan1
            set network-type point-to-point
        end
    config redistribute connected
        set status enable
    end
    config redistribute static
        set status enable
    end
end
end
```

FortiGate_2 OSPF configuration

When configuring FortiGate_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate_2 differs from FortiGate_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

Creating the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```
config system interface
    edit lback1
        set vdom root
        set ip 10.0.0.2 255.255.255.255
        set type loopback
    end
```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

Configuring OSPF area and interfaces - web-based manager

1. On FortiGate_2, go to **Network > OSPF**.
2. Complete the following.

Router ID	10.0.0.2
Areas	Select Create New , enter the Area and Type and then select OK .
Area	0.0.0.0

Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the loopback interface:

IP/Netmask	10.0.0.2/255.255.255.255
Area	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the tunnel interface:

IP/Netmask	10.1.1.0/255.255.255.255
Area	0.0.0.0

- For **Networks**, select **Create New**.
- Enter the following information for the local LAN interface:

IP/Netmask	10.31.101.0/255.255.255.255
Area	0.0.0.0

- Select **Apply**.

Configuring OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel_wan1, you would enter:

```
config router ospf
  set router-id 10.0.0.2
  config area
    edit 0.0.0.0
  end
  config network
    edit 1
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.31.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.0.0.2 255.255.255.255
    end
```

```
config ospf-interface
edit ospf_wan1
set interface tunnel_wan1
set network-type point-to-point
end
end
```

Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

Adding the second IPsec tunnel

The configuration is the same as in [Configuring the IPsec VPN on page 2190](#), but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called tunnel_wan2, you would enter the following on both FortiGate units:

```
config router ospf
config ospf-interface
edit ospf_wan2
set cost 200
set interface tunnel_wan2
set network-type point-to-point
end
end
```

Redundant OSPF routing over IPsec

This example sets up redundant secure communication between two remote networks using an Open Shortest Path First (OSPF) VPN connection. In this example, the HQ FortiGate unit will be called FortiGate 1 and the Branch FortiGate unit will be called FortiGate 2.

The steps include:

1. Creating redundant IPsec tunnels on FortiGate 1.
2. Configuring IP addresses and OSPF on FortiGate 1.
3. Configuring firewall addresses on FortiGate 1.
4. Configuring security policies on FortiGate 1.
5. Creating redundant IPsec tunnels for FortiGate 2.
6. Configuring IP addresses and OSPF on FortiGate 2.
7. Configuring firewall addresses on FortiGate 2.
8. Configuring security policies on FortiGate 2.

Creating redundant IPsec tunnels on FortiGate 1

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan2 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.

3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.1
Remote IP	10.1.1.2

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.1
Remote IP	10.2.1.2

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 1.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 1

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 1's primary and secondary interfaces to connect to FortiGate 2's primary and secondary interfaces.

Creating redundant IPsec tunnels on FortiGate 2

1. Go to **VPN > IPsec Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.
3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.2
Remote IP	10.1.1.1

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.2
Remote IP	10.2.1.1

6. Go to **Network > OSPF** and enter the **Router ID** for FortiGate 2.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 2

1. Go to **Policy & Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create the four security policies required for both FortiGate 2's primary and secondary interfaces to connect to FortiGate 1's primary and secondary interfaces.

Results

1. Go to **Monitor > IPsec Monitor** to verify the statuses of both the primary and secondary IPsec VPN tunnels on FortiGate 1 and FortiGate 2.
2. Go to **Monitor > Routing Monitor**. Monitor to verify the routing table on FortiGate 1 and FortiGate 2. Type **OSPF** for the **Type** and select **Apply Filter** to verify the OSPF route.
3. Verify that traffic flows via the primary tunnel:
 - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracer to a PC2 set to IP address 10.21.1.00 behind FortiGate 2 and vice versa.
 - From PC1, you should see that the traffic goes through 10.1.1.2 which is the primary tunnel interface IP set on FortiGate 2.
 - From PC2, you should see the traffic goes through 10.1.1.1 which is the primary tunnel interface IP set on FortiGate 1.
4. The VPN network between the two OSPF networks uses the primary VPN connection. Disconnect the wan1 interface and confirm that the secondary tunnel will be used automatically to maintain a secure connection.
5. Verify the IPsec VPN tunnel statuses on FortiGate 1 and FortiGate 2. Both FortiGates should show that primary tunnel is DOWN and secondary tunnel is UP.
6. Go to **Monitor > IPsec Monitor** to verify the status.
7. Verify the routing table on FortiGate 1 and FortiGate 2.
The secondary OSPF route (with cost = 100) appears on both FortiGate units.
8. Go to **Monitor > Routing Monitor**. Type **OSPF** for the **Type** and select **Apply Filter** to verify OSPF route.
9. Verify that traffic flows via the secondary tunnel:
 - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracer to a PC2 set to IP:10.21.1.100 behind FortiGate 2 and vice versa.
 - From PC1, you should see that the traffic goes through 10.2.1.2 which is the secondary tunnel interface IP set on FortiGate 2.
 - From PC2, you should see the traffic goes through 10.2.1.1 which is the secondary tunnel interface IP set on FortiGate 1.

OSPF over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows OSPF.

Configuring IPsec on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
  edit "dial-up"
    set type dynamic
    set interface "wan1"
    set mode-cfg enable
    set proposal 3des-sha1
    set add-route disable
    set ipv4-start-ip 10.10.101.0
    set ipv4-end-ip 10.10.101.255
    set psksecret
  next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
  edit "dial-up-p2"
    set phase1name "dial-up"
    set proposal 3des-sha1 aes128-sha1
  next
end
```

Configuring OSPF on FortiGate 1

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
  set router-id 172.20.120.22
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.10.101.0 255.255.255.0
    next
  end
  config redistribute "connected"
    set status enable
  end
  config redistribute "static"
    set status enable
  end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
  edit "dial-up-client"
    set interface "wan1"
    set mode-cfg enable
    set proposal 3des-sha1
    set add-route disable
    set remote-gw 172.20.120.22
    set psksecret
  next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
  edit "dial-up-client"
    set phase1name "dial-up-client"
    set proposal 3des-sha1 aes128-sha1
    set auto-negotiate enable
  next
end
```

Configuring OSPF on FortiGate 2

1. Go to **Dashboard** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
  set router-id 172.20.120.15
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.10.101.0 255.255.255.0
    next
  end
  config redistribute "connected"
    set status enable
  end
  config redistribute "static"
    set status enable
  end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **dial-up-client** to **port5**.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing OSPF traffic from **port5** to **dial-up-client** interfaces.

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via OSPF.
2. From FortiGate 1, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor
```

```
OSPF process 0:
```

Neighbor	ID	Pri	State	Dead	Time	Address	Interface
172.20.120.25	1	Full	/	-	00:00:34	10.10.101.1	dial-up_0

3. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via OSPF.
4. From FortiGate 2, go to **Dashboard**. Enter the CLI Console widget and type this command to verify OSPF neighbors:

```
get router info ospf neighbor
```

```
OSPF process 0:
```

Neighbor	ID	Pri	State	Dead	Time	Address	Interface
172.20.120.22	1	Full	/	-	00:00:30	10.10.101.2	dial-up_client

BGP over dynamic IPsec

The following example shows how to create a dynamic IPsec VPN tunnel that allows BGP.

Configuring IPsec on FortiGate 1

1. Go to **Policy & Objects > Addresses** and select create new **Address**.

Name	Remote_loop_int
Type	Subnet
Subnet/IP Range	10.10.10.10
Interface	any

2. Create an **Address Group**.

Group Name	VPN_DST
Show in Address List	enable
Members	Remote_loop_int all

3. Go to **Dashboard** and enter the CLI Console widget.

4. Create phase 1:

```
config vpn ipsec phase1-interface
edit Dialup
set type dynamic
set interface wan1
set mode aggressive
set peertype one
set mode-cfg enable
set proposal 3des-sha1 aes128-sha1
set peerid dial
set assign-ip disable
set psksecret
next
end
```

5. Create phase 2:

```
config vpn ipsec phase2-interface
edit dial_p2
set phase1name Dialup
set proposal 3des-sha1 aes128-sha1
set src-addr-type name
set dst-addr-type name
set src-name all
set dst-name VPN_DST
```

```

    next
end

```

Configuring BGP on FortiGate 1

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **20.20.20.20/255.255.255.255**.
3. Go to **Dashboard** and enter the CLI Console widget.
4. Create a BGP route.

```

config router bgp
    set as 100
    set router-id 1.1.1.1
    config neighbor
        edit 10.10.10.10
            set ebgp-enforce-multihop enable
            set remote-as 200
            set update-source loop
        next
    end
    config redistribute connected
        set status enable
    end
end

```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **Dashboard** and enter the CLI Console widget.
2. Create phase 1:

```

config vpn ipsec phase1-interface
    edit Dialup
        set interface wan1
        set mode aggressive
        set mode-cfg enable
        set proposal 3des-sha1 aes128-sha1
        set localid dial
        set remote-gw 172.20.120.22
        set assign-ip disable
        set psksecret
    next
end

```

3. Create phase 2:

```

config vpn ipsec phase2-interface
    edit dial_p2
        set phase1name Dialup
        set proposal 3des-sha1 aes128-sha1
        set keepalive enable
    next
end

```

Configuring BGP on FortiGate 2

1. Go to **Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **10.10.10.10/255.255.255.255**.
3. Go to **Dashboard** and enter the **CLI Console** widget.
4. Create a BGP route.

```
config router bgp
  set as 200
  set router-id 1.1.1.2
  config neighbor
    edit 20.20.20.20
      set ebgp-enforce-multihop enable
      set remote-as 100
      set update-source loop
    next
  end
  config redistribute connected
    set status enable
  end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > IPv4 Policy** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Adding a static route on FortiGate 2

Go to **Network > Static Routes** and add a route to the remote Loopback interface via Dialup interface.

Destination IP/Mask	20.20.20.20/255.255.255.255
Device	Dialup
Administrative Distance	10

Verifying the tunnel is up

Go to **Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via BGP.
2. From FortiGate 1, go to **Dashboard**.
3. Enter the **CLI Console** widget and type this command to verify BGP neighbors:

```
get router info bgp summary
```
4. From FortiGate 2, go to **Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via BGP.

5. From FortiGate 2, go to **Dashboard**.
6. Enter the **CLI Console** widget and type this command to verify BGP neighbors:
`get router info bgp summary`

IPsec Auto-Discovery VPN (ADVPN)

Consider a company that wants to provide direct secure (IPsec) connections between all of its offices in New York, Chicago, Greenwich, London, Paris, Frankfurt, Tokyo, Shanghai, and Hong Kong.

A straightforward solution is to create a full mesh of connections such that every site has eight IPsec configurations, one for each of the other sites. If there were ninety sites, that could still be done but now the configuration is becoming tedious, since every time a new site is added, $N-1$ other sites have to have their configuration updated.

An efficient and secure alternative is IPsec Auto-Discovery VPN (ADVPN), which allows a minimum amount of configuration per site but still allows direct IPsec connections to be made between every site. [RFC 7018](#) essentially describes this problem, along with some requirements for candidate solutions.

The ADVPN solution involves partitioning the sites into spokes and hubs such that a spoke has to have enough IPsec configuration to enable it to connect to at least one hub. A hub does not have specific configuration for each spoke, so the amount of configuration does not grow with the number of spokes that are connected to that hub. A hub to hub connection would typically involve both hubs having configuration for each other.

So, one possible partition for the original nine sites would be that Chicago and Greenwich would be spokes for the New York hub, Paris and Frankfurt would be spokes for the London hub, and Tokyo and Hong Kong would be spokes for the Shanghai hub:

Once a spoke has established a connection to its hub then initially IPsec traffic to another site transits via one or more hubs. For example, traffic from Chicago to Hong Kong would transit via the New York and Shanghai hubs. This transit traffic then triggers an attempt to create a more direct connection.

In FortiOS:

- Direct connections are only created between the two endpoints that want to exchange traffic (e.g. Chicago and Hong Kong); we do not create intermediate connections (say Chicago to Shanghai, or New York to Hong Kong) as a side-effect.
- Learning the peer subnets is done via a dynamic routing protocol running over the IPsec connections.
- Negotiation of the direct connections is done via IKE.
- Both PSK and certificate authentication is supported.

Example ADVPN configuration

Since dynamic routing with IPsec under FortiOS requires that an interface have an IP address, then for every site a unique IP address from some unused range is allocated. For example we'll assume that 10.100.0.0/16 is unused and so assign the IP addresses:

- | | | |
|------------------------|-----------------------|------------------------|
| • Chicago 10.100.0.4 | • London 10.100.0.2 | • Frankfurt 10.100.0.7 |
| • Greenwich 10.100.0.5 | • Shanghai 10.100.0.3 | • Hong Kong 10.100.0.8 |
| • New York 10.100.0.1 | • Paris 10.100.0.6 | • Tokyo 10.100.0.9 |

We'll assume that each site has one or more subnets that it protects that it wants to make available to the peers. For the purposes of exposition we'll assume there is only one subnet per site and they are allocated as:

- | | | |
|-------------------------|------------------------|-------------------------|
| • Chicago 10.0.4.0/16 | • London 10.0.2.0/24 | • Frankfurt 10.0.7.0/24 |
| • Greenwich 10.0.5.0/24 | • Shanghai 10.0.3.0/24 | • Hong Kong 10.0.8.0/24 |
| • New York 10.0.1.0/24 | • Paris 10.0.6.0/24 | • Tokyo 10.0.9.0/24 |

Our example network topology now looks like this:

The configuration in Chicago would be as follows:

```
config vpn ipsec phase1-interface
edit "New York"
set type static
set interface wan1
set remote-gw <New-York-IP-address>
set psk <New-York-PSK>
set auto-discovery-receiver enable
next
end
```

The attribute `auto-discovery-receiver` indicates that this IPsec tunnel wishes to participate in an auto-discovery VPN. The IPsec interface would then have its IP assigned according to the Chicago address:

```
config system interface
edit "New York"
set ip 10.100.0.4/32
set remote-ip 10.100.0.1
next
end
```

RIP (for simplicity, you could use OSPF or BGP) is then configured to run on the IPsec interface and on the Chicago subnet (you could use `redistribute connected`, but we'll allow for the fact that there may be other subnets learned from another router on the 10.0.4.0/24 subnet):

```
config router rip
```

```

edit 1
    set prefix 10.100.0.0/16
next
edit 2
    set prefix 10.0.4.0/24
next
end

```

Other than the firewall policy and a minimal phase 2 configuration, this concludes the configuration for Chicago.

Each spoke would have a similar configuration.

The New York hub would have a dynamic phase 1 for its spoke connections, and two static phase 1s for its connections to the other hubs:

```

config vpn ipsec phase1-interface
edit "Spokes"
    set type dynamic
    set interface wan1
    set psk <New-York-PSK>
    set auto-discovery-sender enable
    set auto-discovery-psk enable
    set add-route disable
next
edit "London"
    set type static
    set interface wan1
    set psk <New-York-London-PSK>
    set auto-discovery-forwarder enable
next
edit "Shanghai"
    set type static
    set interface wan1
    set psk <New-York-Shanghai-PSK>
    set auto-discovery-forwarder enable
next
end

```

The 'Spokes' connection has `set auto-discovery-sender enable` to indicate that when IPsec traffic transits the hub it should optionally generate a message to the initiator of the traffic to indicate that it could perhaps establish a more direct connection. The `set add-route disable` ensures that IKE does not automatically add a route back over the spoke and instead leaves routing to a separately configured routing protocol.

The two inter-hub connections have `set auto-discovery-forwarder enable` to indicate that these connections can participate in the auto-discovery process. The interface IP addresses are assigned:

```

config system interface
edit "Spokes"
    set ip 10.100.0.1/32
    set remote-ip 10.100.0.254
next
edit "London"
    set ip 10.100.0.1/32
    set remote-ip 10.100.0.2
next
edit "London"
    set ip 10.100.0.1/32

```

```
        set remote-ip 10.100.0.3
    next
end
```

Following this, RIP is enabled on the relevant interfaces:

```
config router rip
    edit 1
        set prefix 10.100.0.0/16
    next
    edit 2
        set prefix 10.0.1.0/24
    next
end
```

A similar configuration would be used on the other two hubs.

Traffic flow and tunnel connection

With the configuration in place at all spokes and hubs, assuming all the spokes are connected to a hub, then Chicago would learn (via RIP) that the route to the Hong Kong subnet 10.0.8.0/24 is via its "New York" interface. If a device on the Chicago protected subnet (say 10.0.4.45) attempted to send traffic to the Hong Kong protected subnet (say 10.0.8.13) then it should flow over the New York interface to New York, which should then transmit it over the Shanghai tunnel to Shanghai, which should then send it over the dynamically negotiated Hong Kong tunnel to Hong Kong.

At the point when the traffic transits New York it should notice that the Chicago Spoke tunnel and the Shanghai tunnel have auto-discovery enabled, causing the New York hub to send a message via IKE to Chicago informing it that it may want to try and negotiate a direct connection for traffic from 10.0.4.45 to 10.0.8.13.

On receipt of this message, IKE on Chicago creates the (FortiOS-specific) IKE INFORMATIONAL SHORTCUT-QUERY message which contains the Chicago public IP address, the source IP of the traffic (10.0.4.45), the desired destination IP (10.0.8.13), and the PSK that should be used to secure any direct tunnel (if certificates are configured, it is assumed that they all share the same CA and so no additional authentication information is required). This message is sent via IKE to New York since routing indicates that New York is the best route to 10.0.8.13.

On receipt of the IKE INFORMATIONAL query, New York checks its routing table to see who owns 10.0.8.13. It finds that 10.0.8.13 should be routed via Shanghai, and since Shanghai is marked as an auto-discovery-forwarder then the query is forwarded.

Shanghai repeats the process, finds that 10.0.8.13 should be routed via its Hong Kong Spoke and so sends it to Hong Kong. Hong Kong checks 10.0.8.13, finds that it owns the subnet, so it remembers the Chicago public IP address (and PSK) and creates an IKE INFORMATIONAL reply message containing its external IP address. To work out where to send the IKE message, the FortiGate does a routing lookup for the original source IP (10.0.4.45), determines that the message should be routed via its Shanghai tunnel and so sends the reply back to Shanghai. The reply then makes its way back to Chicago following the reverse of the path that it used to arrive at Hong Kong.

When the reply makes it back to the Chicago initiator then it now knows the IP address of the Hong Kong device. Chicago now creates a new dynamic tunnel with the remote gateway as the Hong Kong public IP address and initiates an IKE negotiation (the dynamic tunnel name is auto-generated from the tunnel over which it performed the query; in this case it would be called 'New York_0').

This negotiation should succeed since Hong Kong is set up to expect an attempted negotiation from the Chicago public IP address. Once the negotiation succeeds, RIP will start to run on the newly created tunnels at Chicago and Hong Kong. This will update the routing on Chicago (and Hong Kong) so that the preferred route to 10.0.8.0 (10.0.4.0) is via the newly created tunnel rather than via the connection to New York (Shanghai).

Notes about ADVPN in FortiOS

- Auto-discovery is only supported by IKEv1.
- All Spokes must have an IP address that is routable from any other spoke; devices behind NAT are not currently supported.
- The feature requires the use of a dynamic routing protocol. There is no support for IKE handling routing.
- RIP is not a very scalable routing protocol. When there are more than a few spokes it would be advisable to use route summarization to avoid huge RIP updates. Better yet, use BGP instead of RIP.
- It is assumed that spokes will not be used to transit other spoke traffic, for example: traffic from Chicago to Tokyo would not transit an existing Chicago to Hong Kong tunnel even though that has a shorter hop count than a route via New York and Shanghai.
- There is no facility to allow you to filter which traffic that transits the hub should trigger the message sent to the initiator suggesting it create a direct connection. Currently any and all traffic will trigger it.

Logging and monitoring

This section provides some general logging and monitoring procedures for VPNs.

The following topics are included in this section:

Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels.

Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to **Monitor > IPsec Monitor**.

Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to **Monitor > IPsec Monitor**.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:
 - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.
 - When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.
- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.

- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
 - When a FortiClient dialup client establishes a tunnel:
 - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
 - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
 - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
- When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

VPN event logs

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, Phase 1 and Phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the [FortiGate Log Message Reference](#).

Logging VPN events

1. Go to **Log & Report > Log Settings**.
2. Verify that the **VPN activity event** option is selected.
3. Select **Apply**.

Viewing event logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location**.

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
    set vpn-stats-log ipsec ssl
    set vpn-stats-period 300
end
```

Troubleshooting

This section contains tips to help you with some common challenges of IPsec VPNs.

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

On some FortiGate units, such as the FortiGate 94D, you cannot ping over the IPsec tunnel without first setting a source-IP. In this scenario, you must assign an IP address to the virtual IPsec VPN interface. Anything sourced from the FortiGate going over the VPN will use this IP address.

If the egress/outgoing interface (determined by kernel route) has an IP address, then use the IP address of the egress/outgoing interface. Otherwise, use the IP address of the first interface from the interface list (that has an IP address).

The first diagnostic command worth running, in any IPsec VPN troubleshooting situation, is the following:

```
diagnose vpn tunnel list
```

This command is very useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the SPI identifier, etc. This kind of information in the resulting output can make all the difference in determining the issue with the VPN.

Another appropriate diagnostic command worth trying is:

```
diagnose debug flow
```

This command will inform you of any lack of firewall policy, lack of forwarding route, and of policy ordering issues.

Common IPsec VPN problems

The most common IPsec VPN issues are listed below. Please read thoroughly and note that, although the list is extensive, it is not exhaustive.

This section includes support for the following:

- [Failed VPN connection attempts](#)
- [Debug output table](#)
- [The options to configure policy-based IPsec VPN are unavailable](#)
- [The VPN tunnel goes down frequently](#)
- [The pre-shared key does not match \(PSK mismatch error\)](#)
- [The SA proposals do not match \(SA proposal mismatch\)](#)
- [Pre-existing IPsec VPN tunnels need to be cleared](#)
- [Other potential VPN issues](#)

Failed VPN connection attempts

If your VPN fails to connect, check the following:

- Ensure that the **pre-shared keys** match exactly (see [The pre-shared key does not match \(PSK mismatch error\)](#) below).
- Ensure that both ends use the same P1 and P2 proposal settings (see [The SA proposals do not match \(SA proposal mismatch\)](#) below).
- Ensure that you have allowed inbound and outbound traffic for all necessary network services, especially if services such as DNS or DHCP are having problems.
- Check that a static route has been configured properly to allow routing of VPN traffic.

If you are still unable to connect to the VPN tunnel, run the following diagnostic command in the CLI:

```
diagnose debug application ike -1
diagnose debug enable
```

The resulting output may indicate where the problem is occurring. When you are finished, disable the diagnostics by using the following command:

```
diagnose debug reset
diagnose debug disable
```

View the table below for some assistance in analyzing the debug output.

Debug output table

Problem	Debug output	Common causes	Common solutions
Tunnel is not coming up	Error: negotiation failure	IPsec configuration mismatch	Check phase 1 and 2 settings
	Error: no SA proposal chosen	IPsec configuration mismatch	Check phase 1 and 2 settings
	FortiGate using the wrong VPN	Missing or wrong local ID	If there are more than one pre-shared key dial-up VPN with the same local gateway, use aggressive mode and different local IDs
	Error: connection expiring due to XAUTH failure	Wrong username, password, or user group	Check user credentials and user group configuration
	Error: peer has not completed XAUTH exchange	XAuth is disabled in the client	Fix the client's XAuth configuration
Tunnel is bouncing	DPD packets lost	ISP issue	Check the ISP connection

Problem	Debug output	Common causes	Common solutions
Tunnel is up but traffic does not go through	Error: No matching IPsec selector, drop	Quick mode selector mismatch	Fix the quick mode selector
		NAT is enabled	Disable NAT in the firewall policy
	Traffic is not routed to the tunnel	Route or firewall policy misconfiguration	Route-based: traffic must be routed to IPsec virtual interface Policy-based: traffic must match a firewall policy with action set to IPSEC

The options to configure policy-based IPsec VPN are unavailable

Go to **System > Feature Visibility**. Select **Show More** and turn on **Policy-based IPsec VPN**.

The VPN tunnel goes down frequently

If your VPN tunnel goes down often, check the Phase 2 settings and either increase the **Keylife** value or enable **Autokey Keep Alive**.

The pre-shared key does not match (PSK mismatch error)

It is possible to identify a PSK mismatch using the following combination of CLI commands:

```
diag vpn ike log filter name <phase1-name>
diag debug app ike -1
diag debug enable
```

This will provide you with clues as to any PSK or other proposal issues. If it is a PSK mismatch, you should see something similar to the following output:

```
ike 0:TRX:322: PSK auth failed: probable pre-shared key mismatch
ike Negotiate SA Error:
```

The SA proposals do not match (SA proposal mismatch)

The most common problem with IPsec VPN tunnels is a mismatch between the proposals offered between each party. Without a match and proposal agreement, Phase 1 can never establish. Use the following command to show the proposals presented by both parties.

```
diag debug app ike -1
diag debug enable
```

The resulting output should include something similar to the following, where **blue** represents the remote VPN device, and **green** represents the local FortiGate.

```
responder received SA_INIT msg
incoming proposal:
proposal id = 1:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=AES_CBC (key_len = 256)
    type=INTEGR, val=AUTH_HMAC_SHA_96
    type=PRF, val=PRF_HMAC_SHA
    type=DH_GROUP, val=1536.
```

```

proposal id = 2:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=3DES_CBC
    type=INTEGR, val=AUTH_HMAC_SHA_2_256_128
    type=PRF, val=PRF_HMAC_SHA2_256
    type=DH_GROUP, val=1536.
proposal id = 1:
  protocol = IKEv2:
    encapsulation = IKEv2/none
    type=ENCR, val=AES_CBC (key_len = 128)
    type=INTEGR, val=AUTH_HMAC_SHA_96
    type=PRF, val=PRF_HMAC_SHA
    type=DH_GROUP, val=1536.

```

Pre-existing IPsec VPN tunnels need to be cleared

Should you need to clear an IKE gateway, use the following commands:

```

diagnose vpn ike restart
diagnose vpn ike gateway clear

```

Other potential VPN issues

- Ensure that your FortiGate unit is in NAT mode, rather than Transparent.
- Check your NAT settings, enabling NAT traversal in the Phase 1 configuration while disabling NAT in the security policy. You might need to pin the PAT/NAT session table, or use some of kind of NAT-T keepalive to avoid the expiration of your PAT/NAT translation.
- Ensure that both ends of the VPN tunnel are using Main mode, unless multiple dial-up tunnels are being used.
- Remove any Phase 1 or Phase 2 configurations that are not in use. If a duplicate instance of the VPN tunnel appears on the IPsec Monitor, reboot your FortiGate unit to try and clear the entry.
- If you have multiple dial-up IPsec VPNs, ensure that the peer ID is configured properly on the FortiGate and that clients have specified the correct local ID. Furthermore, in circumstances where multiple remote dialup VPN tunnels exist, each tunnel must have a peer ID set.
- If you are using FortiClient, ensure that your version is compatible with the FortiGate firmware by reading the FortiOS Release Notes.
- If you are using Perfect Forward Secrecy (PFS), ensure that it is used on both peers. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- Ensure that the **Quick Mode selectors** are correctly configured. If part of the setup currently uses firewall addresses or address groups, try changing it to either specify the IP addresses or use an expanded address range. This is especially useful if the remote endpoint is not a FortiGate device.
- If XAUTH is enabled, ensure that the settings are the same for both ends, and that the FortiGate unit is set to **Enable as Server**.
- Check IPsec VPN Maximum Transmission Unit (MTU) size. A 1500 byte MTU is going to exceed the overhead of the ESP-header, including the additional ip_header, etc. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- If your FortiGate unit is behind a NAT device, such as a router, configure port forwarding for UDP ports 500 and 4500.

Troubleshooting connection issues

The following section includes troubleshooting suggestions related to:

- [LAN interface connection](#)
- [Dialup connection](#)
- [Troubleshooting VPN connections](#)
- [Troubleshooting invalid ESP packets using Wireshark](#)
- [Attempting hardware offloading beyond SHA1](#)
- [Check Phase 1 proposal settings](#)
- [Check your routing](#)
- [Try enabling XAuth](#)

LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to **Monitor > IPsec Monitor** where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see [Troubleshooting VPN connections on page 2219](#).

Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking **Monitor > IPsec Monitor**.

Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through [Troubleshooting on page 2215](#), the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing Phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you begin troubleshooting, you must:

- Configure FortiGate units on both ends for interface VPN
- Record the information in your VPN Phase 1 and Phase 2 configurations - for our example here the remote IP address is 10.11.101.10 and the names of the phases are Phase 1 and Phase 2
- Install a telnet or SSH client such as putty that allows logging of output
- Ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.

For this example, default values were used unless stated otherwise.

Obtaining diagnose information for the VPN connection - CLI

1. Log into the CLI as admin with the output being logged to a file.
2. Stop any diagnose debug sessions that are currently running with the CLI command

```
diagnose debug disable
```
3. Clear any existing log-filters by running

```
diagnose vpn ike log-filter clear
```
4. Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is

```
diagnose vpn ike log-filter dst-addr4 10.11.101.10.
```
5. Set up the commands to output the VPN handshaking. The commands are:

```
diagnose debug app ike 255
```

```
diagnose debug enable
```

6. Have the remote FortiGate initiate the VPN connection in the web-based manager by going to **VPN > IPsec Tunnels** and selecting **Bring up**.

This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.

7. Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.

```
diagnose debug disable
```
8. If needed, save the log file of this output to a file on your local computer. Saving the output to a file can make it easier to search for a particular phrase, and is useful for comparisons.

Troubleshooting a Phase 1 VPN connection

Using the output from [Obtaining diagnose information for the VPN connection - CLI](#), search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both Diffie-Hellman Groups 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500
config found
created connection: 0x2f55860 26 10.12.101.10->10.11.101.10:500
```

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500 negotiating
no suitable ISAKMP SA, queuing quick-mode request and initiating ISAKMP SA negotiation
initiator: main mode is sending 1st message...
cookie 3db6afe559e3df0f/0000000000000000
out [encryption]
sent IKE msg (ident=ilsend): 10.12.101.10:500->10.11.101.10:500, len=264,
    id=3db6afe559e3df0f/0000000000000000
diaike 0: comes 10.12.101.1:500->10.11.101.1:500,ifindex=26....
```

Note the phrase “initiator: main mode is sending 1st message...” which shows you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

Troubleshooting invalid ESP packets using Wireshark

The following section provides information to help debug an encryption key mismatch. The ESP packet invalid error is due to an encryption key mismatch after a VPN tunnel has been established. When an IPsec VPN tunnel is up, but traffic is not able to pass through the tunnel, Wireshark (or an equivalent program) can be used to determine whether there is an encryption mismatch. A mismatch could occur for many reasons, one of the most common is the instability of an ISP link (ADSL, Cable), or it could effectively be any device in the physical connection.

The following information is required to troubleshoot the problem.

- Take a packet sniffer trace on both FortiGates.
- Run the `diag vpn tunnel list` command a few times on both FortiGates when generating traffic that will pass through the tunnel.

In the following example, the error message was seen on the recipient FortiGate:

```
date=2010-12-28 time=18:19:35 devname=Kosad_VPN device_id=FG300B3910600118 log_
id=0101037132 type=event subtype=ipsec pri=critical vd="root" msg="IPsec ESP" action="error" rem_
ip=180.87.33.2 loc_ip=121.133.8.18 rem_port=32528 loc_port=4500 out_intf="port2"
cookies="88d40f65d555ccaf/05464e20e4afc835" user="N/A" group="N/A" xauth_user="N/A" xauth_
group="N/A" vpn_tunnel="fortinet_0" status=esp_error error_num=Invalid ESP packet detected (HMAC
validation failed). spi=c32b09f7 seq=00000012
```

This is the output of the command `diag vpn tunnel list` on the FortiGate:

```
inet ver=1 serial=2 192.168.1.205:4500->121.133.8.18:4500 lgwy=dyn tun=intf mode=auto bound_if=4
proxyid_num=1 child_num=0 refcnt=7 ilast=0 olast=0

55	64.797878	121.133.8.18	192.168.1.205	ISAKMP	Informational
56	64.798749	192.168.1.205	121.133.8.18	ISAKMP	Informational
57	64.957383	121.133.8.18	192.168.1.205	ISAKMP	Informational

How to verify if the original packet has been encrypted correctly

To verify, it is necessary to decrypt the ESP packet using Wireshark. Open the packet capture that is taken from initiator FortiGate using Wireshark. Go to **Edit > Preferences**, expand **Protocol** and look for **ESP**. Select **"Attempt to detect/decode encrypted ESP payloads"**, and fill in the information for the encryption algorithm and the keys. This information can be obtained from the output of the command `diag vpn tunnel list`.

If the packet was encrypted correctly using the correct key, then the decryption will be successful and it will be possible to see the original package as shown below:

13	16.199042	121.133.8.18	192.168.1.205	ISAKMP	Informational
14	16.199103	192.168.1.205	100.100.100.202	ICMP	echo (ping) request
15	21.150599	192.168.1.205	121.133.8.18	ISAKMP	Informational
16	21.223916	121.133.8.18	192.168.1.205	ISAKMP	Informational
17	21.324790	192.168.1.205	121.133.8.18	ISAKMP	Informational
18	21.392073	121.133.8.18	192.168.1.205	ISAKMP	Informational
19	24.187008	192.168.1.205	100.100.100.202	ICMP	echo (ping) request
20	26.392870	192.168.1.205	121.133.8.18	ISAKMP	Informational
21	26.746759	121.133.8.18	192.168.1.205	ISAKMP	Informational
22	26.747595	192.168.1.205	121.133.8.18	ISAKMP	Informational
23	26.999062	121.133.8.18	192.168.1.205	ISAKMP	Informational
24	29.687170	192.168.1.205	100.100.100.202	ICMP	echo (ping) request
25	31.092890	192.168.1.205	121.133.8.18	ISAKMP	Informational
26	32.245204	121.133.8.18	192.168.1.205	ISAKMP	Informational
27	32.245590	192.168.1.205	121.133.8.18	ISAKMP	Informational
28	32.288780	121.133.8.18	192.168.1.205	ISAKMP	Informational
29	35.187275	192.168.1.205	100.100.100.202	ICMP	echo (ping) request
30	37.382867	192.168.1.205	121.133.8.18	ISAKMP	Informational
31	37.936742	121.133.8.18	192.168.1.205	ISAKMP	Informational

Repeat the decryption process for the packet capture from the recipient firewall. If the decryption failed using the same key, the packet may be corrupted and the interface should then be checked for CRC or packet errors.

Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option—all VPN processing must be done in software—unless using an NP6 (although the NP4lite variation also supports SHA256, SHA384, and SHA512).

Enable/disable IPsec ASIC-offloading

Much like NPU-offload in IKE phase1 configuration, you can enable or disable the usage of ASIC hardware for IPsec Diffie-Hellman key exchange and IPsec ESP traffic. By default hardware offloading is used. For debugging purposes, sometimes it is best for all the traffic to be processed by software.

```
config sys global
    set ipsec-asic-offload [enable | disable]
end
```

Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

NPU offloading is supported when the local gateway is a loopback interface.

Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See [General troubleshooting tips on page 2223](#).
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.
3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.
4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:
 - The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
 - The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
 - If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
 - The remote client must have at least one set of Phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
 - Both VPN peers must have the same NAT traversal setting (enabled or disabled).
 - The remote client must have at least one set of Phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
 - If you are using manual keys to establish a tunnel, the **Remote SPI** setting on the FortiGate unit must be identical to the **Local SPI** setting on the remote peer, and vice versa.
5. To correct the problem, see the following table.

VPN troubleshooting tips

Configuration problem	Correction
Mode settings do not match.	Select complementary mode settings. See Phase 1 parameters on page 2048 .

Configuration problem	Correction
Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.	<p>Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see Phase 1 parameters on page 2048).</p> <p>If you are configuring authentication parameters for FortiClient dialup clients, refer to the Authenticating FortiClient Dialup Clients Technical Note.</p>
Preshared keys do not match.	Reenter the preshared key. See Phase 1 parameters on page 2048 .
Phase 1 or Phase 2 key exchange proposals are mismatched.	Make sure that both VPN peers have at least one set of proposals in common for each phase. See Phase 1 parameters on page 2048 and Phase 2 parameters on page 2067 .
NAT traversal settings are mismatched.	Select or clear both options as required. See Phase 1 parameters on page 2048 and Phase 1 parameters on page 2048 .

A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see [Phase 1 parameters on page 2048](#).

Troubleshooting L2TP and IPsec

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- [Quick checks](#)
- [Mac OS X and L2TP](#)
- [Setting up logging](#)
- [Using the FortiGate unit debug commands](#)

Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check the settings, including encapsulation setting, which must be transport-mode.</p> <p>Check the user password.</p> <p>Confirm that the user is a member of the user group assigned to L2TP.</p> <p>On the Windows PC, check that the IPsec service is running and has not been disabled. See Troubleshooting L2TP and IPsec on page 2224.</p>
Tunnel connects, but there is no communication.	<p>Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See Troubleshooting L2TP and IPsec on page 2224.</p>

Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Prior to FortiOS 4.0 MR3, FortiOS refused L2TP connections with empty AVP host names in compliance with [RFC 2661](#) and [RFC 3931](#).

Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

Configuring FortiGate logging for L2TP over IPsec

1. Go to **Log & Report > Log Settings**.
2. Select **Event Log**.
3. Select the **VPN activity event** check box.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the **Log location** if required.
3. After each attempt to start the L2TP over IPsec VPN, select **Refresh** to view logged events.

Using the FortiGate unit debug commands

Viewing debug output for IKE and L2TP

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```

3. Attempt to use the VPN and note the debug output in the SSH or Telnet session.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Using the packet sniffer

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```

3. Attempt to use the VPN and note the debug output.
4. Enter **Ctrl-C** to end sniffer operation.

Typical L2TP over IPsec session startup log entries - raw format

Troubleshooting GRE over IPsec

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	<p>Use the <code>execute ping</code> command to ping the Cisco device public interface.</p> <p>Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.</p>
IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check that the encryption and authentication settings match those on the Cisco device.</p> <p>Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.</p>
Tunnel connects, but there is no communication.	<p>Check the security policies. See Troubleshooting GRE over IPsec on page 2227.</p> <p>Check routing. See Troubleshooting GRE over IPsec on page 2227.</p>

Setting up logging

Configuring FortiGate logging for IPsec

1. Go to **Log & Report > Log Settings**.
2. Select the **Event Logging**.

3. Select **VPN activity event**.
4. Select **Apply**.

Viewing FortiGate logs

1. Go to **Log & Report > VPN Events**.
2. Select the log storage type.
3. Select **Refresh** to view any logged events.

GRE tunnel keepalives

In the event that each GRE tunnel endpoint has keepalive enabled, firewall policies allowing GRE are required in both directions. The policy should be configured as follows (where the IP addresses and interface names are for example purposes only):

```
config firewall policy
  edit < id >
    set srcintf "gre"
    set dstintf "port1"
    set srcaddr "1.1.1.1"
    set dstaddr "2.2.2.2"
    set action accept
    set schedule "always"
    set service "GRE"
  next
end
```

Cisco compatible keep-alive support for GRE

The FortiGate can send a GRE keepalive response to a Cisco device to detect a GRE tunnel. If it fails, it will remove any routes over the GRE interface.

Configuring keepalive query - CLI:

```
config system gre-tunnel
  edit <id>
    set keepalive-interval <value: 0-32767>
    set keepalive-failtimes <value: 1-255>
  next
end
```

GRE tunnel with multicast traffic

If you want multicast traffic to traverse the GRE tunnel, you need to configure a multicast policy as well as enable multicast forwarding.

- To configure a multicast policy, use the `config firewall multicast-policy` command.
- To enable multicast forwarding, use the following commands:

```
config system settings
  set multicast-forward enable
end
```

Using diagnostic commands

There are some diagnostic commands that can provide useful information. When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

Using the packet sniffer - CLI:

1. Enter the following CLI command:

```
diag sniff packet any icmp 4
```

2. Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:

```
114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
```

3. Enter CTRL-C to stop the sniffer.

Viewing debug output for IKE - CLI:

1. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug enable
```

2. Attempt to use the VPN or set up the VPN tunnel and note the debug output.
3. Enter CTRL-C to stop the debug output.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Chapter 17 - IPv6

IPv6

The origins of Internet Protocol Version 6 (IPv6) date back to December 1998 with the publication of [RFC 2460](#), which describes IPv6 as the successor to IPv4, the standard communications protocol still in use by the majority of users today. This transition away from IPv4 was a direct response to the foreseeable exhaustion of 32-bit IPv4 addresses, which are virtually all but assigned—all 4.3 billion.

IPv4 uses 32-bit addresses, which means that there is a theoretical address limit of 2 to the power of 32. The IPv6 address scheme is based on a 128-bit address, resulting in a theoretical address limit of 2 to the power of 128.

Possible addresses:

IPv4 = Roughly 4.3 billion

IPv6 = Over 340 undecillion (340 followed by 36 digits)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices, so it's unlikely that we will ever need to worry about the availability of IPv6 addresses.

Aside from the difference of possible addresses, there is also the different formatting of the addresses. A computer would view an IPv4 address as a 32-bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period:

```
10101100.00010000.11111110.00000001
```

To make the number more user-friendly, we translate the address into decimal, again 4 octets separated by a period:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128-bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon:

```
0010000000000001:0000110110111:0000000000000000:000000000000010:0000000000000000:0000000000000000:0000000000000000:0000000000000000
```

To make this number a little more user-friendly, we translate it into hexadecimal, again 8 octets separated by a colon, for example:

```
2001:0db8:0000:0002:0000:0000:0000:0020
```

We can further simplify the above address. Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, the above address can be reduced to:

```
2001:0db8:0000:0002:0:0:0:20
```

or

```
2001:db8:0:2::20
```

IPv6 packet structure

Each IPv6 packet consists of a mandatory fixed header and optional extension headers, and carries a payload, which is typically either a datagram and/or Transport Layer information. The payload could also contain data for the Internet Layer or Link Layer. Unlike IPv4, IPv6 packets aren't fragmented by routers, requiring hosts to implement Maximum Transmission Unit (MTU) Path Discovery for MTUs larger than the smallest MTU (which is 1280 octets).

Jumbograms and jumbo payloads

In IPv6, packets which exceed the MTU of the underlying network are labelled jumbograms, which consist of a jumbo payload. A jumbogram typically exceeds the IP MTU size limit of 65,535 octets, and provides the jumbo payload option, which can allow up to nearly 4GiB of payload data, as defined in [RFC 2675](#). When the MTU is determined to be too large, the receiving host sends a 'Packet too Big' ICMPv6 type 2 message to the sender.

Fragmentation and reassembly

As noted, packets that are too large for the MTU require hosts to perform MTU Path Discovery to determine the maximum size of packets to send. Packets that are too large require a 'Fragment' extension header, to divide the payload into segments that are 8 octets in length (except for the last fragment, which is smaller). Packets are reassembled according to the extension header and the fragment offset.

Benefits of IPv6

Some of the benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local, and global address space

What's new for IPv6 in FortiOS 5.6

IPv6 (5.6.3)

New IPv6 features added to FortiOS 5.6.3:

IPv6 RADIUS support (402437, 439773)

Added support for IPv6 RADIUS authentication. When configuring the FortiGate interface and the RADIUS server (under `config system interface` and `config user radius` respectively), the server IP address can be set as IPv6.

Added support for IPv6 Fortisandbox (424290) (447153)

FortiOS can now communicate with a FortiSandbox if the FortiSandbox has an IPv6 IP address.

IPv6 captive portal support (435435)

Captive portal now supports IPv6 addresses; works with remote RADIUS authentication and WiFi interfaces.

FortiGate can reply to an anycast probe from the interface's unicast address (308872)

A new setting has been added within the CLI that can enable the FortiGate to reply to an anycast probe from the FortiGate's unicast IP address.

```
config system global
  set ipv6-allow-anycast-probe [enable|disable]
end
```

Enable: Enable probing of IPv6 address space through Anycast, by responding from the unicast IP address

Disable: Disable probing of IPv6 address space through Anycast

Secure Neighbor Discovery (355946)

Additional settings have been added to the configuration for interfaces with IPv6 so that they comply more closely to the parameters of RFC 3971

The context of the new settings is

```
config system interface
  edit <interface>
    config ipv6
```

The new options with IPv6 are:

ndmode

Neighbor discovery mode

```
set ndmode [basic | SEND]
```

Basic: Does not support SEND.

SEND-compatible: Supports SEND.

nd-cert

Neighbor discovery certificate

```
set nd-cert <string of Name of certificate to be used>
```

Example string: "Fortinet_Factory local"

n-security-level

Neighbor discovery security level

```
set nd-security-level <integer>
```

- Integer values from 0 - 7
- 0 = least secure
- 7 = most secure
- default = 0

nd-timestamp-delta -

Neighbor discovery timestamp delta value

```
set nd-timestamp-delta <integer of time in seconds>
```

- Range: 1 - 3600 sec
- default = 300

nd-timestamp-fuzz

Neighbor discovery timestamp fuzz factor

```
set nd-timestamp-fuzz <integer of time in seconds>
```

- Range: 1 - 60 sec
- default = 1

Additional related technical information

Kerenl

- Redirects ICMPv6 packets to user space if they require SEND options verification or build.

Radvd

- Verifies NS/RS SEND options including CGA, RSA, Timestamp, NONCE, etc. Daemon also creates neighbor cache for future timestamp checking, any entry gets flushed in 4 hours.
- Helps kernel build NA/RA SEND options including CGA, RSA, Timestamp, NONCE, etc. CGA parameters are kept in cache for each interface. CGA modifier is kept in CMDB.

Diagnose command for radvd

```
diag test application radvd
```

- Shows statistics
- Toggles message dump

Add multicast-PMTU to allow FGT to send ICMPv6 Too Big Message (373396)

New multicast-PMTU feature added to better comply with RFC 4443.

Normally, a "Packet Too Big" icmp6 message is sent by a routing device in response to a packet that it cannot forward because the packet is larger than the MTU of the outgoing link. For security reasons, these message may be disabled because attackers can use the information about a victim's ip address as the source address to do IP address spoofing.

In FortiOS's implementation of this function, a setting in the CLI, has been added to make this behavior optional on the FortiGate.

The syntax for the option is:

```
config router multicast6
  set multicast-PMTU [enable|disable]
end
```

IPv6 Features

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. Go to **System > Config > Features**, enable IPv6, and click **Apply**.

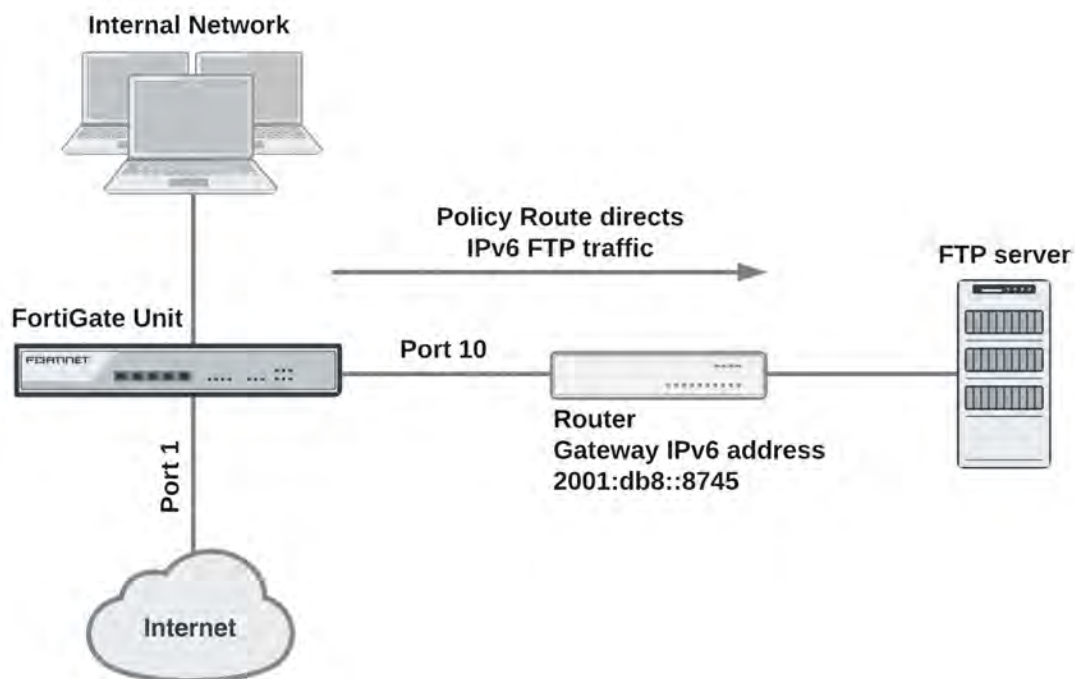

The following IPv6 features are available from the FortiOS web manager:

IPv6 policies

IPv6 security policies are created both for an IPv6 network and a transitional network. A transitional network is a network that is transitioning over to IPv6 but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature under **System > Config > Features**.

IPv6 policy route

IPv6 policy routing

IPv6 policy routing functions in the same way as IPv4 policy routing. To add an IPv6 policy route, go to **Network > Policy Routes** and select **Create New > IPv6 Policy Route**.

Adding an IPv6 Policy route

New Routing Policy

If incoming traffic matches:

Protocol: ☐ TCP ☐ UDP ☒ **ANY** ☐ Specify

Incoming interface:

Source address / mask:

Destination address / mask:

Type of Service: Bit Pattern Bit Mask

Then:

Outgoing interface:

Gateway Address:

Comments: 0/255

You can also use the following command to add IPv6 policy routes:

```
config router policy6
  edit 0
    set input-device <interface>
    set src <ipv6_ip>
    set dst <ipv6_ip>
    set protocol <0-255>
    set gateway <ipv6_ip>
    set output-device <interface>
    set tos <bit_pattern>
    set tos-mask <bit_mask>
  end
```

IPv6 security policies

IPv6 security policies support all the features supported by IPv4 security policies:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP, and ICAP).
- All traffic shaping options, including: shared traffic shaping, reverse shared traffic shaping, and per-IP traffic shaping.
- All user and device authentication options.

IPv6 explicit web proxy

You can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Enter the following CLI command to enable the IPv6 explicit web proxy:

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

2. Go to **Network > Interfaces** and edit the **internal** interface, select **Enable Explicit Web Proxy** and select **OK**.
3. Go to **Policy & Objects > Proxy Policy** and select **Create New** to add an IPv6 explicit web proxy security policy with the following settings shown.

This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy, you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Example IPv6 Explicit Web Proxy security policy

New Policy	
Explicit Proxy Type	<input checked="" type="radio"/> Web <input type="radio"/> FTP
Enabled On	internal ?
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy, use the following command:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
```

```
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
  set outgoing-ip6 2001:db8:0:2::50
end
```

VIP64

VIP64 policies can be used to configure static NAT virtual IPv6 address for IPv4 addresses. VIP64 can be configured from the CLI using the following commands:

```
config firewall vip64
  edit <zname_str>
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv6>[-address_ipv6]
    set extport <port_int>
    set id <id_num_str>
    set mappedip [<start_ipv4>-<end_ipv4>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <addr_str>
  end
```

VIP64 CLI Variables and Defaults

Variable	Description	Default
<zname_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.

Variable	Description	Default
<code>extip <address_ipv6>[-address_ipv6]</code>	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set <code>extip</code> to <code>::</code>.</p>	<code>::</code>
<code>extport <port_int></code>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if <code>portforward</code> is enabled.</p> <p>If <code>portforward</code> is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set <code>extport</code> to the first port number in the range. Then set <code>mappedport</code> to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the <code>extport</code> port number range.</p>	0
<code>id <id_num_str></code>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.

Variable	Description	Default
mappedip [<start_ipv4>-<end_ipv4>]	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	0.0.0.0
mappedport <port_int>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
portforward {enable disable}	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
src-filter <addr_str>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x:x:x:x:x:x/n). Separate addresses with spaces.	null

VIP46 policies can be used to configure static NAT virtual IPv4 address for IPv6 addresses. VIP46 can be configured from the CLI using the following commands (see the table below for variable details):

```
config firewall vip46
  edit <name_str>
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv4>[-address_ipv4]
    set extport <port_int>
```

```

    set id <id_num_str>
    set mappedip [<start_ipv6>-<end_ipv6>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <add_str>
end

```

VIP46 CLI Variables and Defaults

Variable	Description	Default
<name_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.
extip <address_ipv4>[- address_ipv4]	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set <code>extip</code> to 0.0.0.0.</p>	0.0.0.0

Variable	Description	Default
<code>extport <port_int></code>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if <code>portforward</code> is enabled.</p> <p>If <code>portforward</code> is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set <code>extport</code> to the first port number in the range. Then set <code>mappedport</code> to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the <code>extport</code> port number range.</p>	0
<code>id <id_num_str></code>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
<code>mappedip [<start_ipv6>-<end_ipv6>]</code>	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	::

Variable	Description	Default
<code>mappedport <port_int></code>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
<code>portforward {enable disable}</code>	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
<code>src-filter <addr_str></code>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x.x.x.x/n). Separate addresses with spaces.	null

IPv6 Network Address Translation

NAT66, NAT64, and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities with IPv6-IPv4 tunnelling or dual stack configurations. The commands are available only in the CLI.

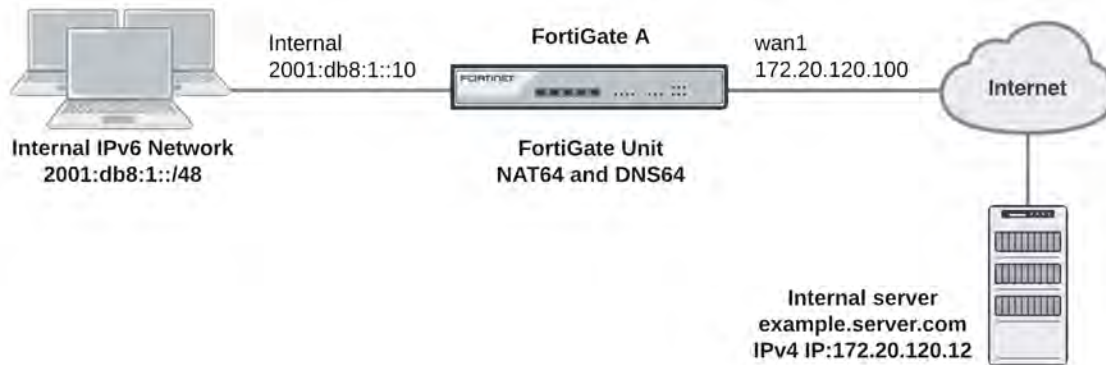

Fortinet supports all features described in [RFC 6146](#). However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in [RFC 6147](#).

NAT64 and DNS64 (DNS proxy)

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. 'DNS proxy' and 'DNS64' are interchangeable terms.

Example NAT64 configuration

With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform the IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

To enable NAT64 and DNS64, use the following CLI commands:

Enable NAT64

```
config system nat64
  set status enable
end
```

Enable the DNS proxy on the IPv6 interface

```
config system dns-server
  edit internal
  end
```

In your DHCP6 configuration, configure the IPv6 interface IP address as the DNS6 server IP address. The FortiGate will proxy DNS requests to the system DNS server.

```
config system dhcp6 server
  edit 1
    set interface internal
    config ip-range
      edit 1
        set start-ip 2001:db8:1::11
        set end-ip 2001:db8:1::20
      end
    set dns-server1 2001:db8:1::10
  end
```

NAT64 policies

You can configure security policies for NAT64 using the web-based manager. For these options to appear, the feature must be enabled using **System > Feature Visibility**. You can then configure the policies under **Policy & Objects > NAT64 Policy**.

NAT64 policies and can also be configured from the CLI using the following command:

```
config firewall policy64
```

In the following section, you will configure a NAT64 policy that allows connections from an internal IPv6 network to an external IPv4 network.

Configuring NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example, the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to an IPv4 address in the range 172.20.120.200 to 172.20.120.210.

Enter the following command to enable NAT64:

```
config system nat64
    set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix from the well-known prefix of 64:ff9b::/96 and setting `always-synthesize-aaaa-record` to enable (default), the DNS proxy does not check for AAAA records but rather synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
    set status enable
    set nat64-prefix 64:ff9b::/96
    set always-synthesize-aaaa-record enable
end
```

Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
    edit internal-net6
        set ip6 2001:db8:1::/48
    end
```

Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
    edit external-net4
        set subnet 172.20.120.0/24
        set associated-interface wan1
    end
```

Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
```

```
edit exit-pool4
    set startip 172.20.120.200
    set endip 172.20.120.210
end
```

Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
config firewall policy64
    edit 0
        set srcintf internal
        set srcaddr internal-net6
        set dstintf wan1
        set dstaddr external-net4
        set action accept
        set schedule always
        set service ALL
        set logtraffic enable
        set ippool enable
        set poolname exit-pool4
    end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, which can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

How a host on the internal IPv6 network communicates with `example.server.com` that only has IPv4 address on the Internet

1. The host on the internal network does a DNS lookup for `example.server.com` by sending a DNS query for an AAAA record for `example.server.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for `example.server.com`.
4. The previous step is skipped if `always-synthesize-aaaa-record` is enabled.
5. The DNS proxy performs an A-record query for `example.server.com` and gets back an RRSet containing a single A record with the IPv4 address `172.20.120.12`.
6. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.20.120.12`.
7. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.20.120.12`.
8. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
9. The FortiGate unit translates the destination address of the packets from IPv6 address `64:ff9b::172.20.120.12` to IPv4 address `172.20.120.12` and translates the source address of the packets to `172.20.120.200` (or another address in the IP pool range) and forwards the packets out the `wan1` interface to the Internet.

NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as

much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy from the CLI. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT):

```
config firewall policy6
edit 0
set srcintf internal
set dstintf wan1
set srcaddr internal_net
set dstaddr all
set action accept
set schedule always
set service ALL
set nat enable
end
```

It's also useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
config firewall ippool6
edit example_6_pool
set startip 2001:db8::
set endip 2001:db8::
end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
config firewall address6
edit device_address
set ip6 2001:db8::132/128
end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
edit 0
set srcintf internal
set dstintf wan1
set srcaddr device_address
set dstaddr all
set action accept
set schedule always
set service ALL
set nat enable
set ippool enable
set poolname example_6_pool
end
```

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps the destination address 2001:db8::dd to 2001:db8::ee.

```
config firewall vip6
  edit example-vip6
    set extip 2001:db8::dd
    set mappedip 2001:db8::ee
  end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee.

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr example-vip6
    set action accept
    set schedule always
    set service ALL
  end
```

NAT64 and NAT66 session failover

The FortiGate Clustering Protocol (FGCP) supports IPv6, NAT64, and NAT66 session failover. If session pickup is enabled, these sessions are synchronized between cluster members and, after an HA failover, the sessions will resume with only minimal interruption.

NAT46

NAT46 is used to translate IPv4 addresses to IPv6 addresses so that a client on an IPv4 network can communicate transparently with a server on an IPv6 network.

To enable NAT46, use the following CLI command:

```
config firewall vip46
```

NAT46 policies

Security policies for NAT46 can be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using **System > Feature Visibility**. You can then configure the policies under **Policy & Objects > NAT46 Policy**.

NAT46 policies can also be configured from the CLI using the following command:

```
config firewall policy46
```

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in [RFC 4443](#).

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It is also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.
- ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).
- ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

- Destination Unreachable
- Time Exceeded
- Packet Too Big
- Parameter Problems
- Information messages are divided into three groups:
 - Diagnostic messages
 - Neighbor Discovery messages
 - Messages for the management of multicast groups.

ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 – 127 are error messages and type codes 128 – 255 are for information messages.

ICMPv6 Types and Codes

Type #	Type Name	Code
0	Reserved	0 - no route to destination
		1 - communication with destination administratively prohibited
		2 - beyond scope of source address
		3 - address unreachable
		4 - port unreachable
		5 - source address failed ingress/egress policy
		6 - reject route to destination
		7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit
		1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered
		1 - unrecognized Next Header type encountered
		2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	
128	Echo Request	
129	Echo Replay	
130	Multicast Listener Query	

Type #	Type Name	Code
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command
		1 - Router Renumbering Result
		255 - Sequence Number Reset
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query.
		1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP.
		2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty.
		1 - The Responder refuses to supply the answer. The Reply Data field will be empty.
		2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	

Type #	Type Name	Code
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Feature Visibility**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Dual stack routing

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses.

In FortiOS, dual stack architecture it is not comprised merely of basic addressing functions that operate in both versions of IP. The other features of the appliance, such as UTM and routing, can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunnelling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

IPv6 tunnelling

IPv6 Tunnelling is the act of tunnelling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. Unlike NAT, once the packet reaches its final destination, the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network.

The key to IPv6 tunnelling is the ability of the two devices to be dual stack compatible in order to work with both IPv4 and IPv6 at the same time. In the process, the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet, removes the IPv4 header, updates the IPv6 header, and processes the packet.

There are two types of tunnels in IPv6:

Automatic tunnels: Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunnelled to.

Configured tunnels: Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel configuration

There are a few ways in which the tunnelling can be performed depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Host to Host: Dual Stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.

Network Device to Host: Dual Stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

The node that does the encapsulation needs to maintain soft state information about each tunnel in order to process the IPv6 packets.

Use the following command to tunnel IPv6 traffic over an IPv4 network. The IPv6 interface is configured under `config system interface`. The command to do the reverse is `config system ipv6-tunnel`. These commands are not available in Transparent mode.

```
config system sit-tunnel
  edit <tunnel name>
    set destination <tunnel _address>
    set interface <name>
    set ip6 <address_ipv6>
    set source <address_ipv4>
  end
```

Variable	Description	Default
<code>edit <tunnel_name></code>	Enter a name for the IPv6 tunnel.	No default.
<code>destination <tunnel_address></code>	The destination IPv4 address for this tunnel.	0.0.0.0
<code>interface <name></code>	The interface used to send and receive traffic for this tunnel.	No default.
<code>ip6 <address_ipv6></code>	The IPv6 address for this tunnel.	No default.
<code>source <address_ipv4></code>	The source IPv4 address for this tunnel.	0.0.0.0

Tunnelling IPv6 through IPsec VPN

A variation on tunnelling IPv6 through IPv4 is to use an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, two networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the FortiGate units and a tunnel is created over the IPv4-based Internet, but the traffic in the tunnel is IPv6. This has the additional advantage of securing the traffic.

For configuration information, see [IPv6 IPsec VPN on page 2264](#).

SIP over IPv6

FortiOS supports Sessions Initiate Protocol (SIP) over IPv6. The SIP application-level gateway (ALG) can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown below, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIB entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:

```
fgSysSes6Count
fgSysSes6Rate1
fgSysSes6Rate10
fgSysSes6Rate30
fgSysSes6Rate60
```

- IPv6 Policy Statistics:

```
fgFwPol6StatsTable
fgFwPol6StatsEntry
FgFwPol6StatsEntry
fgFwPol6ID
fgFwPol6PktCount
fgFwPol6ByteCount
```

- IPv6 Session Statistics:

```
fgIp6SessStatsTable
fgIp6SessStatsEntry
FgIp6SessStatsEntry
fgIp6SessNumber
```

The `fgSysSesCount` and `fgSysSesRateX` MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

New OIDs

The following OIDs have been added:

```

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo
.fgSysSes6Count      1.3.6.1.4.1.12356.101.4.1.15
.fgSysSesRate1       1.3.6.1.4.1.12356.101.4.1.16
.fgSysSesRate10      1.3.6.1.4.1.12356.101.4.1.17
.fgSysSesRate30      1.3.6.1.4.1.12356.101.4.1.18
.fgSysSesRate60      1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID      1.3.6.1.4.1.12356.101.5.1.2.2.1.1
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount 1.3.6.1.4.1.12356.101.5.1.2.2.1.
2
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount 1.3.6.1.4.1.12356.101.5.1.2.2.1
.3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProtoTables
.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber 1.3.6.1.4.1.12356.101.11.2.3.1.1

```

EXAMPLE SNMP get/walk output

```

// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4
FORTINET-FORTIGATE-MIB::fgSysSes6Count.0 = Gauge32: 203
FORTINET-FORTIGATE-MIB::fgSysSes6Rate1.0 = Gauge32: 10 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate10.0 = Gauge32: 2 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate30.0 = Gauge32: 1 Sessions Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate60.0 = Gauge32: 0 Sessions Per Second

// FwPolicy6 table:

FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89

```

IPv6 Per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```

config firewall policy6
edit 0
set per-ip-shaper "new-perip-shaper"
end

```

DHCPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Feature Visibility** and enabling **IPv6**.

Use the CLI command

```
config system dhcp6
```

For more information on the configuration options, see the [FortiGate CLI Reference](#).

DHCP delegated mode

Downstream IPv6 interfaces can receive address assignments on delegated subnets from a DHCP server that serves an upstream interface.

DHCPv6-PD configuration

Enable DHCPv6 Prefix Delegation on upstream interface (port10):

```
config system interface
  edit "port10"
    config ipv6
      set dhcp6-prefix-delegation enable
    end
  end
```

Assign delegated prefix on downstream interface (port1). Optionally, specific delegated prefixes can be specified:

```
config system interface
  edit "port1"
    config ipv6
      set ip6-mode delegated
      set ip6-upstream-interface "port10"
      set ip6-subnet ::1:0:0:0:1/64
      set ip6-send-adv enable
      config ipv6-delegated-prefix-list
        edit 1
          set upstream-interface "port10"
          set autonomous-flag enable
          set onlink-flag enable
          set subnet 0:0:0:100::/64
        end
      end
    end
  end
```

DHCPv6 Server configuration

Configuring a server that uses delegated prefix and DNS from upstream:

```
config system dhcp6 server
  edit 1
    set dns-service delegated
```

```
set interface "wan2"
set upstream-interface "wan1"
set ip-mode delegated
set subnet 0:0:0:102::/64
end
```

DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back. The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
edit internal
config ipv6
set dhcp6-relay-service enable
set dhcp6-relay-type regular
set dhcp6-relay-ip 2001:db8:0:2::30
end
```

IPv6 forwarding

Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP

FortiOS fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, virus scanning, and web filtering.

To add flow-based inspection to IPv6 traffic go to **Policy & Objects > IPv6 Policy** and select **Create New** to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Under **Security Profiles**, select the profiles to apply to the traffic.

Obtaining IPv6 addresses from an IPv6 DHCP server

From the CLI, you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
edit wan2
config ipv6
set ip6-mode dhcp
end
```

Authentication Support

RADIUS

FortiOS's supports IPv6 RADIUS authentication. When configuring the FortiGate interface and the RADIUS server (under `config system interface` and `config user radius` respectively), the server IP address can be set as IPv6.

Captive portal

Captive portal supports IPv6. It works with remote RADIUS authentication and WiFi interfaces.

IPv6 Configuration

This section contains configuration information for IPv6 on FortiOS. Attempts are made to include scenarios in each section to better assist with the configuration and to orient the information toward a particular task.

You will find information on the following:

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

IPv6 address groups

To create IPv6 address groups from existing IPv6 addresses - web-based manager

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

1. Go to **Policy & Objects > Addresses** and select **Create New > Address Group**.
2. Select **IPv6 Group**, and fill out the fields with the following information:

Group Name	Web_Server_Cluster
Members	Web_Server-1
	Web_Server-2
	Web_Server-3

3. Select **OK**.

To create IPv6 address groups from existing IPv6 addresses - CLI

```
config firewall addrgrp6
  edit Web_Server_Cluster
    set member Web_Server-1 Web_Server-2 Web_Server-3
  end
```

To verify that the addresses were added correctly

1. Go to **Policy & Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. From the CLI, enter the following commands:

```
config firewall addgrp6
edit <the name of the address that you wish to verify>
Show full-configuration
```

IPv6 address ranges

You can configure IPv6 address ranges in both the GUI and the CLI.

To configure IPv6 address ranges - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Set the **Type** to **IP Range** and enter the IPv6 addresses as shown:

To configure IPv6 address ranges - CLI:

```
config firewall address6
edit ipv6range
set type iprange
set start-ip 2001:db8:0:2::30
set end-ip 2001:db8:0:2::31
end
```

IPv6 firewall addresses

Scenario: Mail Server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network. This server is on the network off of port1.

- The IP address is 2001:db8:0:2::20/128
- There should be a tag for this address being for a server.

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Mail_Server
Type	Subnet
IPv6 Address	2001:db8:0:2::20/128

3. Select **OK**.

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
edit Mail_Server
set type ipprefix
set subnet 2001:db8:0:2::20/128
end
```

Scenario: First Floor Network

You need to create an IPv6 address for the subnet of the internal network off of Port1. These computers connect to port1. The network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx

There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects > Objects > Addresses**
2. Select **Create New > Address**. Select **IPv6 Address** and fill out the fields with the following information:

Name	Internal_Subnet_1
Type	Subnet / IP Range
IPv6 Address	2001:db8:0:2::/64
Comments	Network for 1st Floor

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall address6
edit Internal_Subnet_1
set comment "Network for 1st Floor"
set type ipprefix
set subnet 2001:db8:0:2::/64
end
```

Scenario: Accounting Team

You need to create an IPv6 address for the Accounting Team that's on the 1st Floor. These users are off of various ports of the FortiGate, but they have all been assigned addresses between 2001:db8:0:2::2000 and 2001:db8:0:2::a000

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Accounting_Team
-------------	-----------------

Type	IP Range
Subnet / IP Range	2001:db8:0:2::2000-2001:db8:0:2::a000

3. Select **OK**.

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
edit Accounting_Team
set type iprange
set visibility enable
set start-ip 2001:db8:0:2::2000
set end-ip 2001:db8:0:2::a000
end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects > Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address6
edit <the name of the address that you wish to verify>
Show full-configuration
```

ICMPv6

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

To configure ICMPv6 - web-based manager:

1. Go to **Policy & Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	diagnostic-test1
Service Type	Firewall
Show in Service List	Enabled
Category	Uncategorized
Protocol Type	ICMP6
Type	140

3. Select **OK**.
 4. Enter the following CLI command:
- ```
config firewall service custom
```

```

edit diagnostic-test1
 set protocol ICMP6
 set icmptype 140
 set icmpcode 0
 set visibility enable
end

```

**To verify that the category was added correctly:**

1. Go to **Policy & Objects > Services**. Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```

config firewall service custom
 edit <the name of the service that you wish to verify>
 show full-configuration

```

## IPv6 IPsec VPN

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

**To enable IPv6:**

1. Go to **System > Features**.
2. Select **IPv6** and click **Apply**.

The topics in this section include:

- [Overview of IPv6 IPsec support](#)
- [Configuring IPv6 IPsec VPNs](#)
- [Site-to-site IPv6 over IPv6 VPN example](#)
- [Site-to-site IPv4 over IPv6 VPN example](#)
- [Site-to-site IPv6 over IPv4 VPN example](#)

### Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can also combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

#### IPv4 over IPv6

The VPN gateways have IPv6 addresses.

The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.

**IPv6 over IPv4**

The VPN gateways have IPv4 addresses.

The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

**Certificates**

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

**Configuring IPv6 IPsec VPNs**

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies, and routing.

**Phase 1 configuration**

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to 6. Its default value is 4. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
edit tunnel6
 set ip-version 6
 set remote-gw6 0:123:4567::1234
 set interface port3
 set proposal 3des-md5
end
```

**Phase 2 configuration**

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default "0.0.0.0/0" address for Source address and Destination address to the IPv6 value ":::0". If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, ":::0" for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
edit tunnel6_p2
 set phasename tunnel6
 set proposal 3des-md5
 set src-addr-type subnet6
```

```
 set dst-addr-type subnet6
end
```

## Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

## Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

### To create a static route - web-based manager:

1. Go to **Network > Static Routes**.
2. Select the drop-down arrow on the **Create New** button and select **IPv6 Route**.
3. Enter the information and select **OK**.

### To create a static route - CLI:

1. In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

```
config router static6
 edit 1
 set device port2
 set dst 0::/0
 next
 edit 2
 set device toB
 set dst fec0:0000:0000:0004::/64
 next
end
```

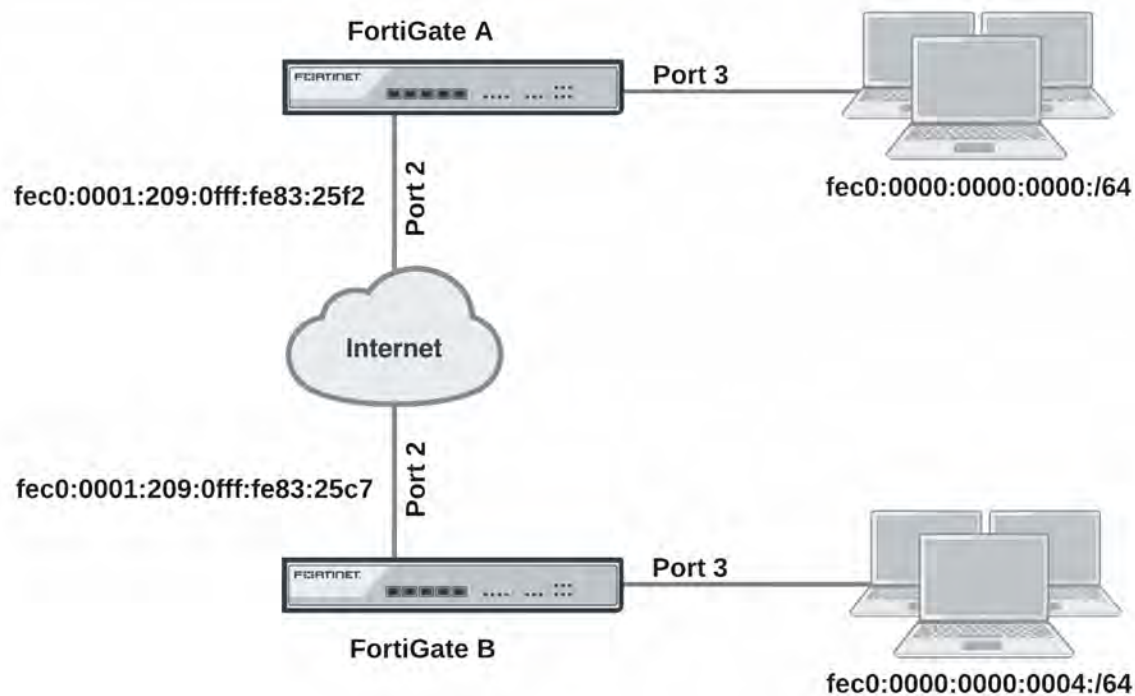

If the VPN is IPv4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

## Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

### Example IPv6-over-IPv6 VPN topology

### Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```

config system interface
 edit port2
 config ipv6
 set ip6-address fec0::0001:209:0fff:fe83:25f2/64
 end
 next
 edit port3
 config ipv6
 set ip6-address fec0::0000:209:0fff:fe83:25f3/64
 end
 next
end

```

### Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```

config vpn ipsec phase1-interface
 edit toB
 set ip-version 6
 set interface port2

```

```

 set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
end

```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```

config vpn ipsec phase2-interface
edit toB2
 set phase1name toB
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 set src-addr-type subnet6
 set dst-addr-type subnet6
end

```

### Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```

config firewall policy6
edit 1
 set srcintf port3
 set dstintf toB
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
next
edit 2
 set srcintf toB
 set dstintf port3
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
end

```

### Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```

config router static6
edit 1
 set device port2
 set dst 0::/0
next
edit 2
 set device toB
 set dst fec0:0000:0000:0004::/64
end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```
config system interface
 edit port2
 config ipv6
 set ip6-address fec0::0003:209:0fff:fe83:25c7/64
 end
 next
 edit port3
 config ipv6
 set ip6-address fec0::0004:209:0fff:fe83:2569/64
 end
 end
config vpn ipsec phase1-interface
 edit toA
 set ip-version 6
 set interface port2
 set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
 end
config vpn ipsec phase2-interface
 edit toA2
 set phase1name toA
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 set src-addr-type subnet6
 set dst-addr-type subnet6
 end
config firewall policy6
 edit 1
 set srcintf port3
 set dstintf toA
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
 next
 edit 2
 set srcintf toA
 set dstintf port3
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
 end
config router static6
 edit 1
```

```

 set device port2
 set dst 0::/0
 next
 edit 2
 set device toA
 set dst fec0:0000:0000:0000::/64
 end

```

### Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

#### Example IPv4-over-IPv6 VPN topology

#### Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```

config system interface
 edit port2
 config ipv6
 set ip6-address fec0::0001:209:0fff:fe83:25f2/64
 end
 next
 edit port3
 set 192.168.2.1/24
 end

```

## Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
 edit toB
 set ip-version 6
 set interface port2
 set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
 end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
 edit toB2
 set phase1name toB
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 end
```

## Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
 edit 1
 set srcintf port3
 set dstintf toB
 set srcaddr all
 set dstaddr all
 set action accept
 set service ALL
 set schedule always
 next
 edit 2
 set srcintf toB
 set dstintf port3
 set srcaddr all
 set dstaddr all
 set action accept
 set service ALL
 set schedule always
 end
```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
 edit 1
 set device port2
```

```

 set dst 0::/0
 next
 edit 2
 set device toB
 set dst 192.168.3.0/24
 end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```

config system interface
 edit port2
 config ipv6
 set ip6-address fec0::0003:fe83:25c7/64
 end
 next
 edit port3
 set 192.168.3.1/24
 end
config vpn ipsec phase1-interface
 edit toA
 set ip-version 6
 set interface port2
 set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
 end
config vpn ipsec phase2-interface
 edit toA2
 set phase1name toA
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 end
config firewall policy
 edit 1
 set srcintf port3
 set dstintf toA
 set srcaddr all
 set dstaddr all
 set action accept
 set service ALL
 set schedule always
 next
 edit 2
 set srcintf toA
 set dstintf port3
 set srcaddr all
 set dstaddr all

```

```

 set action accept
 set service ALL
 set schedule always
 end
 config router static6
 edit 1
 set device port2
 set dst 0::/0
 next
 edit 2
 set device toA
 set dst 192.168.2.0/24
 end

```

### Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

#### Example IPv6-over-IPv4 VPN topology

### Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```

config system interface
 edit port2
 set 10.0.0.1/24
 next

```

```

next
edit port3
config ipv6
 set ip6-address fec0::0001:209:0fff:fe83:25f3/64
end

```

### Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```

config vpn ipsec phase1-interface
edit toB
 set interface port2
 set remote-gw 10.0.1.1
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
end

```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```

config vpn ipsec phase2-interface
edit toB2
 set phase1name toB
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 set src-addr-type subnet6
 set dst-addr-type subnet6
end

```

### Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction.

Define the address `all6` using the `firewall address6` command as `::/0`.

```

config firewall policy6
edit 1
 set srcintf port3
 set dstintf toB
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
next
edit 2
 set srcintf toB
 set dstintf port3
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
end

```

### Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
 edit 1
 set device toB
 set dst fec0:0000:0000:0004::/64
 end
config router static
 edit 1
 set device port2
 set dst 0.0.0.0/0
 set gateway 10.0.0.254
 end
```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
 edit port2
 set 10.0.1.1/24
 next
 edit port3
 config ipv6
 set ip6-address fec0::0004:209:0fff:fe83:2569/64
 end
config vpn ipsec phase1-interface
 edit toA
 set interface port2
 set remote-gw 10.0.0.1
 set dpd enable
 set psksecret maryhadalittlelamb
 set proposal 3des-md5 3des-sha1
 end
config vpn ipsec phase2-interface
 edit toA2
 set phase1name toA
 set proposal 3des-md5 3des-sha1
 set pfs enable
 set replay enable
 set src-addr-type subnet6
 set dst-addr-type subnet6
 end
config firewall policy6
 edit 1
 set srcintf port3
 set dstintf toA
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
 next
 edit 2
 set srcintf toA
 set dstintf port3
 set srcaddr all6
 set dstaddr all6
 set action accept
 set service ALL
 set schedule always
 end
config router static6
 edit 1
 set device toA
```

```

 set dst fec0:0000:0000:0000::/64
 end
 config router static
 edit 1
 set device port2
 set gateway 10.0.1.254
 end
 end

```

## TCP MSS values

TCP MSS values, which control the maximum amount of data that can be sent in a single packet, can be set for IPv6 policies (for both the sender and the receiver). You can configure TCP MSS values in IPv6 using the following CLI commands:

```

config firewall policy6
 edit <index_int>
 set tcp-mss-sender <value>
 set tcp-mss-receiver <value>
 end

```

## BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

IPv6 BGP commands include:

```

config router bgp
 set activate6 {enable | disable}
 set allowas-in6 <max_num_AS_integer>
 set allowas-in-enable6 {enable | disable}
 set as-override6 {enable | disable}
 set attribute-unchanged6 [as-path] [med] [next-hop]
 set capability-default-originate6 {enable | disable}
 set capability-graceful-restart6 {enable | disable}
 set default-originate-route-map6 <routemap_str>
 set distribute-list-in6 <access-list-name_str>
 set distribute-list-out6 <access-list-name_str>
 set filter-list-in6 <aspath-list-name_str>
 set filter-list-out6 <aspath-list-name_str>
 set maximum-prefix6 <prefix_integer>
 set maximum-prefix-threshold6 <percentage_integer>
 set maximum-prefix-warning-only6 {enable | disable}
 set next-hop-self6 {enable | disable}
 set prefix-list-in6 <prefix-list-name_str>
 set prefix-list-out6 <prefix-list-name_str>
 set remove-private-as6 {enable | disable}
 set route-map-in6 <routemap-name_str>
 set route-map-out6 <routemap-name_str>
 set route-reflector-client6 {enable | disable}
 set route-server-client6 {enable | disable}
 set send-community6 {both | disable | extended | standard}
 set soft-reconfiguration6 {enable | disable}
 set unsuppress-map6 <route-map-name_str>

```

```
config network6
config redistribute6
end
```

## RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

- [Network layout and assumptions](#)
- [Configuring the FortiGate units system information](#)
- [Configuring RIPng on FortiGate units](#)
- [Configuring other network devices](#)
- [Testing the configuration](#)
- [Debugging IPv6 on RIPng](#)

### Network layout and assumptions

#### Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

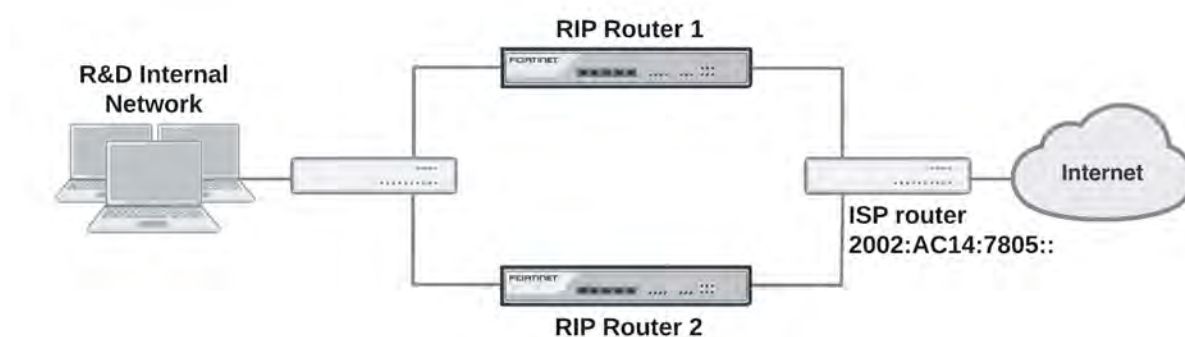

Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows:

### Rip example network topology

| Network | Router  | Interface & Alias | IPv6 address             |
|---------|---------|-------------------|--------------------------|
| R&D     | Router1 | port1 (internal)  | 2002:A0B:6565:0:0:0:0:0  |
|         |         | port2 (ISP)       | 2002:AC14:7865:0:0:0:0:0 |
|         | Router2 | port1 (internal)  | 2002:A0B:6566:0:0:0:0:0  |
|         |         | port2 (ISP)       | 2002:AC14:7866:0:0:0:0:0 |

### Network topology for the IPv6 RIPng example

### Assumptions

The following assumptions have been made concerning this example:

- All FortiGate units have 5.0+ firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

### Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

#### To configure system information on Router1 - web-based manager:

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter "Router1".
4. Go to **System > Feature Visibility**.
5. Enable **IPv6** and click **Apply**.

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

|                              |                      |
|------------------------------|----------------------|
| <b>Alias</b>                 | internal             |
| <b>IP/Netmask</b>            | 2002:A0B:6565::/0    |
| <b>Administrative Access</b> | HTTPS SSH PING       |
| <b>Description</b>           | Internal RnD network |
| <b>Administrative Status</b> | Up                   |

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

|                              |                    |
|------------------------------|--------------------|
| <b>Alias</b>                 | ISP                |
| <b>IP/Netmask</b>            | 2002:AC14:7865::/0 |
| <b>Administrative Access</b> | HTTPS SSH PING     |
| <b>Description</b>           | ISP and internet   |
| <b>Administrative Status</b> | Up                 |

#### To configure system information on Router1 - CLI:

```

config system global
 set hostname Router1
 set gui-ipv6 enable
end
config system interface
 edit port1
 set alias internal
 set allowaccess https ping ssh
 set description "Internal RnD network"
 config ipv6
 set ip6-address 2002:a0b:6565::/0
 end
 next
 edit port2
 set alias ISP
 set allowaccess https ping ssh
 set description "ISP and internet"
 config ipv6
 set ip6-address 2002:AC14:7865::
 end
 end
end

```

**To configure system information on Router2 - web-based manager:**

1. Go to **Dashboard**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Feature Visibility**.
5. Enable **IPv6** and click **Apply**.
6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

|                              |                      |
|------------------------------|----------------------|
| <b>Alias</b>                 | internal             |
| <b>IP/Netmask</b>            | 2002:A0B:6566::/0    |
| <b>Administrative Access</b> | HTTPS SSH PING       |
| <b>Description</b>           | Internal RnD network |
| <b>Administrative Status</b> | Up                   |

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

|                              |                    |
|------------------------------|--------------------|
| <b>Alias</b>                 | ISP                |
| <b>IP/Netmask</b>            | 2002:AC14:7866::/0 |
| <b>Administrative Access</b> | HTTPS SSH PING     |
| <b>Description</b>           | ISP and internet   |
| <b>Administrative Status</b> | Up                 |

**To configure system information on Router2 - CLI:**

```

config system global
 set hostname Router2
 set gui-ipv6 enable
end
config system interface
 edit port1
 set alias internal
 set allowaccess https ping ssh
 set description "Internal RnD network"
 config ipv6
 set ip6-address 2002:a0b:6566::/0
 end
 next
 edit port2
 set alias ISP
 set allowaccess https ping ssh
 set description "ISP and internet"

```

```
config ipv6
 set ip6-address 2002:AC14:7866::
end
end
```

## Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

### To configure RIPng on Router1 - CLI:

```
config router ripng
 config interface
 edit port1
 next
 edit port2
 end
 config neighbor
 edit 1
 set interface port1
 set ipv6 2002:a0b:6566::/0
 next
 edit 2
 set interface port2
 set ipv6 2002:AC14:7805::/0
 end
end
```

### To configure RIPng on Router2 - CLI:

```
config router ripng
 config interface
 edit port1
 next
 edit port2
 end
 config neighbor
 edit 1
 set interface port1
 set ipv6 2002:a0b:6565::/0
 next
 edit 2
 set interface port2
 set ipv6 2002:AC14:7805::/0
 end
end
```

## Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

## Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

### Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

## Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

Turn on debugging in general

Set the debug level to information, a verbose reporting level

Turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

## IPv6 RSSO support

RADIUS Single Sign-On (RSSO) is supported in IPv6, but can only be configured in the CLI:

```
config firewall policy6
 edit <id>
 set rso enable
 set fall-through-unauthenticated enable
 end
```

## IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
 edit 1
 set interface "port1"
 set srcaddr6 "all"
 set dstaddr6 "all"
 set service6 "ALL"
 set ips-sensor-status enable
 set ips-sensor "all_default"
 next
end
```

## Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax:

```
config firewall ipv6-eh-filter.
```

The following commands are now available:

- `set hop-opt {disable | enable}`: Block packets with Hop-by-Hop Options header.
- `set dest-opt {disable | enable}`: Block packets with Destination Options header.
- `set hdopt-type <integer>`: Block specific Hop-by-Hop and/or Destination Option types (maximum 7 types, each between 0 and 255).
- `set routing {disable | enable}`: Block packets with Routing header.
- `set routing-type <integer>`: Block specific Routing header types (maximum 7 types, each between 0 and 255).
- `set fragment {disable | enable}`: Block packets with Fragment header.
- `set auth {disable | enable}`: Block packets with Authentication header.
- `set no-next {disable | enable}`: Block packets with No Next header.

## IPv6 Denial of Service policies

Denial of Service (DoS) policies can now be configured by going to **Policy & Objects > IPv6 DoS Policy**. For more information, refer to the “Interface Policies” section of the [FortiOS Handbook Firewall](#) chapter.

## Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host. You can also configure the host for both traps and queries. You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

Use the following command to add two hosts to an SNMP community:

```
config system snmp community
 config hosts
 edit 1
 set ip 172.20.120.1
 set host-type query
 end
 config hosts6
 edit 1
 set ip 2001:db8:0:2::30
 set host-type trap
 end
```

## IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with [RFC 4601](#). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
 set multicast-routing {enable | disable}
 config interface
 edit <interface-name>
 set hello-interval <1-65535 seconds>
 set hello-holdtime <1-65535 seconds>
 end
 config pim-sm-global
 config rp-address
 edit <index>
 set ipv6-address <ipv6-address>
 end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

# Chapter 18 - Logging and Reporting

## Logging and reporting

Welcome and thank you for selecting Fortinet products for your network protection. This document provides detailed information that explains how to take advantage of your FortiGate's ability to log and report activity, whether you need to monitor network stability, log traffic offsite for security reasons, provide bandwidth usage reports, or one of many other possible functions.

Logging is an integral component of the FortiGate system. Logging allows you to view the activity and status of the traffic passing through your network, and monitor for anomalies.

If you notice problems with this document, or have suggestions for improvements, send an email about them to Fortinet Technical Document at [techdoc@fortinet.com](mailto:techdoc@fortinet.com).

## Before you begin

Before you begin using this guide, please ensure that:

- You have administrative access to the web-based manager and/or CLI.
- The FortiGate unit is integrated into your network.
- The operation mode has been configured.
- The system time, DNS settings, administrator password, and network interfaces have been configured.
- Firmware, FortiGuard Antivirus and FortiGuard Antispam updates are completed.

While using the instructions in this guide, note that administrators are assumed to be super\_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

## How this guide is organized

This document contains information about how to find the right log device for your logging requirements, how to enable and configure logging to that device, and a detailed explanation of each log type log message.

This FortiOS Handbook chapter contains the following sections:

[Logging and reporting overview](#) provides general information about logging. We recommend that you begin with this chapter as it contains information for both beginners and advanced users as well. It contains an explanation of log messages, files, and devices, and an overview of the Reporting functions.

[Logging and reporting for small networks](#) provides an overview of setting up a small network for logging, with a look at a possible setup with a backup solution and a customized report.

[Logging and reporting for large networks](#) provides an overview of setting up a larger, enterprise-level network, with configuration of multiple FortiGate units, multiple FortiAnalyzer units as a backup solution, and a sample procedure for creating a more intensive and broad report to suit the larger network.

[Advanced logging](#) provides a series of separate tutorials for possible tasks and procedures an advanced user may want to undertake with their FortiGate-powered network. It contains explanations of advanced backup, logging, and report solutions.

[Troubleshooting and logging](#) provides a short overview of how log messages can be used to identify and solve problems within the network, how to identify and solve logging database issues, and how to solve connection issues between FortiGate and FortiAnalyzer units.

## What's new in FortiOS 5.6

This section describes new Logging and Reporting features added to FortiOS 5.6.0, 5.6.1, 5.6.3, and 5.6.4.

### FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

#### Automatic synchronization of log display location

In previous versions, log display location could differ between Log & Report and FortiView, which could result in empty log screens if the two were not synchronized. As of 5.6.4, both log viewers automatically pick the best available log device. A different log device can be manually selected.

As a result, the associated CLI command `log gui-display location` has been removed.

### FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

#### Improve FortiAnalyzer storage usage on Log Settings page (409658)

This feature improves FortiAnalyzer storage usage information in log settings to include more detailed per-ADOM information as follows:

- (1) FAZ ADOM (Name)  
Size / Used
- (2) Indexed Logs  
Used / Available  
Data Policy Days Configured / Actual
- (3) Compressed Logs  
Used / Available  
Data Policy Days Configured / Actual

#### Range change for maximum log age (440633)

The value range for "maximum-log-age" under "config log disk setting" has been limited to 0-3650.

#### New connect and disconnect event logs for FSSO server status change (446263)

Connect and disconnect event logs for FSSO server status changes have been added according to the following:

- When FSSO server status changes from disconnected to connected, record one connected event.
- When FSSO server status changes from connected to disconnected, record one disconnected event and send one FSSO server disconnected alert email when set.

These logs must be enabled in the CLI.

### Syntax

```
config alertemail setting
 set FSSO-disconnect-logs
```

### Security Fabric audit result logging to FortiGuard (452588)

The CLI now includes an option for the user to enable (by default) or disable FortiGuard security fabric audit result submission.

If enabled, every time a user runs the Security Fabric audit test on the FortiGate, the audit result will be sent to FortiGuard. When disabled, no audit data is sent to FortiGuard.

Security Audit categories have been reorganized and renamed to reflect the categories as they are in the security audit matrix.

### Syntax

```
config system global
 set fortiguard-audit-result-submission [enable | disable]
end
```

### Config log disk uploadtime units change (400999)

Instructions for upload time under "config log disk setting" has been clarified by adding the phrase 'daily upload' and mentioning that this is the Hour. The help text also now includes the acceptable range for more clarity.

### Log field extension policy-name and meta-field (455441)

An option to include the policy name field has been added to traffic logs (log-policy-name). Likewise, an option to add a meta-field tag to all logs has also been added (custom-field and custom-log-fields; see below). This meta-field could be used for identifying the fortigate sending the logs, for example.

These options can only be enabled in the CLI.

### Syntax

```
config log setting
 set log-policy-name [enable | disable]
end
config log custom-field
 edit "aaa"
 set name "fieldda"
 set value "111"
 next
end
config log setting
 set custom-log-fields "aaa"
end
```

### Rename logtime to eventtime (454445)

The "logtime" field in logs has been renamed to "eventtime" to avoid confusion. The logtime is the timestamp that miglogd receives the message.

## FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

### Usability Updates to Reports Page (383684)

The **Reports** page has been updated in 5.6.1, to include both FortiCloud and Local Reports in a single location. Configuring of report schedules is also available on this page. The page will display whichever format is enabled, or allow switching between both if both Local and FortiCloud are in use.

### Interface Categories (srcintfrole, etc) added to log data (434188)

In 5.6, logs and FortiView both sort log traffic into two interface categories: "Traffic from LAN/DMZ", and "Traffic from WAN." For greater compatibility and troubleshooting of FortiAnalyzer and FortiCloud setups, interface category fields that expose this information have been added to general log data in 5.6.1: `srcintfrole` and `dstintfrole` for better backend control and monitoring.

## FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

### All string values in log messages are enclosed in double quotes (399871)

In previous versions, some string log fields have double quotes and some do not. FortiOS 5.6 adds double-quotes to all string fields in all log messages.

Some example log messages:

```
date=2017-01-27 time=10:46:26 logid="0001000014" type="traffic"
subtype="local" level="notice" vd="vd1" srcip=172.16.200.1 srcport=17856
srcintf=unknown-0 dstip=192.168.100.206 dstport=53 dstintf="port1"
sessionid=1461 proto=17 action="accept" policyid=0 dstcountry="Reserved"
srccountry="Reserved" trandisp="noop" service="DNS" app="DNS" duration=180
sentbyte=92 rcvdbyte=0 sentpkt=1 rcvdpkt=0 appcat="unscanned"
```

```
date=2017-01-27 time=10:36:34 logid="0107045071" type="event"
subtype="endpoint" level="notice" vd="vd1" logdesc="FortiClient Vulnerability
Scan" scantime=1467851105 fctuid="A8BA0B12DA694E47BA4ADF24F8358E2F"
user="test-user" srcip=192.168.25.26 srcname="test-pc"
srcmac="01:02:03:04:05:06" devtype="Windows PC" vulnid=25894
vulnname="Security Vulnerability CVE-2016-0636 in Oracle JDK"
vulncat="Applications" severity="critical" cveid="CVE-2016-0636"
vendorurl="http://www.oracle.com/technetwork/topics/security/alert-cve-2016-
0636-2949497.html" msg="Endpoint Vulnerability Scan."
```

### Client and server certificates included in Application control log messages (406203)

When SSL/TLS traffic triggers an application control signature, the application control log messages now include information about the signatures used by the session. This includes the client certificate issuer, the name in the server certificate, and the server certificate issuer.

## DNS Logging (401757)

FortiOS logging now includes the Detailed DNS log message type. DNS events were previously recorded as event logs. In FortiOS 5.6 DNS log messages are a new category that also includes more DNS log messages to provide additional detail about DNS activity through the FortiGate. You can enable DNS logging from the CLI using the following command (shown in this example for memory logging):

```
config log memory filter
 set dns enable
end
```

DNS log messages include details of each DNS query and response. DNS log messages are recorded for all DNS traffic though the FortiGate and originated by the FortiGate.

The detailed DNS logs can be used for low-impact security investigation. Most network activity involves DNS activity of some kinds. Analyzing DNS logs can provide a lot of details about the activity on your network without using flow or proxy-based resource intensive techniques.

## Added Policy Comment logging option (387865)

As an alternative to custom log fields, the functionality has been added to log a policy's comment field in all traffic log files that use that policy, in order to sort/isolate logs effectively with larger deployments and VDOMs. The feature is disabled by default.

```
config log setting
 set log policy comment [enable/disable]
```

## FortiAnalyzer encryption option name change (399191)

For clarity, and because the default options for `config log fortianalyzer setting` have now changed, the option `default` has now been changed to `high-medium` in the following CLI commands:

```
config log fortianalyzer setting
 set enc-algorithm [high/high-medium/low]
config log fortianalyzer override-setting
 set enc-algorithm [high/high-medium/low]
config log fortiguard setting
 set enc-algorithm [high/high-medium/low]
config log fortiguard override-setting
 set enc-algorithm [high/high-medium/low]
```

## Logging and reporting overview

Logging and reporting in FortiOS can help you in determining what is happening on your network, as well as informing you of certain network activity, such as detection of a virus or IPsec VPN tunnel errors. Logging and reporting go hand in hand, and can become a valuable tool for information as well as helping to show others the activity that is happening on the network.

This section explains logging and reporting features that are available in FortiOS, and how they can be used to help you manage or troubleshoot issues. This includes how the FortiGate unit records logs, what a log message is, and what the log database is.

### What is logging?

Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

After a log message is recorded, it is stored within a log file which is then stored on a log device. A log device is a central storage location for log messages. The FortiGate unit supports several log devices, such as FortiAnalyzer units, the FortiCloud service, and Syslog servers. A FortiGate unit's system memory and local disk can also be configured to store logs, and because of this, are also considered log devices.

You must subscribe to FortiCloud before you will be able to configure the FortiGate unit to send logs to a FortiCloud server.

---

When the recorded activity needs to be read in a more human way, the FortiGate unit can generate a Report. A report gathers all the log information that is needed for the report, and presents it in a graphical format, with customizable design and automatically generated charts. Reports can be used to present a graphical representation of what is going on in the network. Reports can also be generated on a FortiAnalyzer unit; if you want to generate reports on a FortiAnalyzer, see the [FortiAnalyzer documentation](#) to help you create and generate those reports.

### How the FortiGate unit records log messages

The FortiGate unit records log messages in a specific order, storing them on a log device. The order of how the FortiGate unit records log messages is as follows:

1. Incoming traffic is scanned.
2. During the scanning process, the FortiGate unit performs necessary actions, and simultaneously records the actions and results.
3. Log messages are sent to the log device.

#### Example: How the FortiGate unit records a DLP event

1. The FortiGate unit receives incoming traffic and scans for any matches associated within its firewall policies containing a DLP sensor.
2. A match is found; the DLP sensor, `dlp_sensor`, had a rule within it called All-HTTP with the action Exempt applied to the rule. The sensor also has Enable Logging selected, which indicates to the FortiGate unit that the activity should be recorded and placed in the DLP log file.

3. The FortiGate unit exempts the match, and places the recorded activity (the log message) within the DLP log file.
4. According to the log settings that were configured, logs are stored on the FortiGate unit's local hard drive. The FortiGate unit places the DLP log file on the local hard drive.

## FortiOS features available for logging

Logs record FortiGate activity, providing detailed information about what is happening on your network. This recorded activity is found in log files, which are stored on a log device. However, logging FortiGate activity requires configuring certain settings so that the FortiGate unit can record the activity. These settings are often referred to as log settings, and are found in most security profiles, but also in **Log & Report > Log Settings**.

Log settings provide the information that the FortiGate unit needs so that it knows what activities to record. This topic explains what activity each log file records, as well as additional information about the log file, which will help you determine what FortiGate activity the FortiGate unit should record.

### Traffic

Traffic logs record the traffic that is flowing through your FortiGate unit. Since traffic needs firewall policies to properly flow through the unit, this type of logging is also referred to as firewall policy logging. Firewall policies control all traffic that attempts to pass through the FortiGate unit, between FortiGate interfaces, zones and VLAN sub-interfaces.

Logging traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic)
- packet comes into an inbound interface
- a possible log packet is sent regarding a match in the firewall policy, such as a URL filter
- traffic log packet is sent, per firewall policy
- packet passes and is sent out an interface

Traffic log messages are stored in the traffic log file. Traffic logs can be stored any log device, even system memory.

All security profile-related logs are now tracked within the Traffic logs, as of FortiOS 5.0, so all forward traffic can be searched in one place, such as if you are looking to see all activity from a particular address, security feature or traffic. Security profile logs are still tracked separately in the **Security Log** section, which only appears when logs exist.

If you have enabled and configured WAN Optimization, you can enable logging of this activity in the CLI using the `config wanopt setting` command. These logs contain information about WAN Optimization activity and are found in the traffic log file. When configuring logging of this activity, you must also enable logging within the security policy itself, so that the activity is properly recorded.

### Sniffer

The Sniffer log records all traffic that passes through a particular interface that has been configured to act as a One-Armed Sniffer, so it can be examined separately from the rest of the Traffic logs.

### Other Traffic

The traffic log also records interface traffic logging, which is referred to as Other Traffic. Other Traffic is enabled only in the CLI. When enabled, the FortiGate unit records traffic activity on interfaces as well as firewall policies.

Logging Other Traffic puts a significant system load on the FortiGate unit and should be used only when necessary.

Logging other traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic) and other-traffic
- packet comes into an interface
- interface log packet is sent to the traffic log that is enabled on that particular interface
- possible log packet is sent regarding a match in the firewall policy, such as URL filter
- interface log packet is sent to the traffic log if enabled on that particular interface
- packet passes and is sent out an interface
- interface log packet is sent to traffic (if enabled) on that particular interface

## Event

The event log records administration management as well as FortiGate system activity, such as when a configuration has changed, admin login, or high availability (HA) events occur. Event logs are an important log file to record because they record FortiGate system activity, which provides valuable information about how your FortiGate unit is performing.

Event logs help you in the following ways:

- keeping track of configuration setting changes
- IPsec negotiation, SSL VPN and tunnel activity
- quarantine events, such as banned users
- system performance
- HA events and alerts
- firewall authentication events
- wireless events on models with WiFi capabilities
- activities concerning modem and internet protocols L2TP, PPP and PPPoE
- VIP activities
- AMC disk's bypass mode
- VoIP activities that include SIP and SCCP protocols.

As of 5.4, every 'execute' CLI command now generates an 'audit' event log, allowing you to track configuration changes. You can enable/disable this feature in the CLI:

```
config system global
 set cli-audit-log [enable|disable]
end
```

The FortiGate unit records event logs only when events are enabled.

## Traffic Shaping

Traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings can be applied to a firewall policy, appearing within the traffic log messages.

By enabling this feature, you can see what traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings are being used.

## Data Leak Prevention

Data Leak Prevention logs, or DLP logs, provide valuable information about the sensitive data trying to get through to your network as well as any unwanted data trying to get into your network. The DLP rules within a DLP sensor can log the following traffic types:

- email (SMTP, POP3 or IMAP; if SSL content SMTPS, POP3S, and IMAPS)
- HTTP
- HTTPS
- FTP
- NNTP
- IM

A DLP sensor must have log settings enabled for each DLP rule and compound rule, as well as applied to a firewall policy so that the FortiGate unit records this type of activity. A DLP sensor can also contain archiving options, which these logs are then archived to the log device.

## NAC Quarantine

Within the DLP sensor, there is an option for enabling NAC Quarantine. The NAC Quarantine option allows the FortiGate unit to record details of DLP operation that involve the ban and quarantine actions, and sends these to the event log file. The NAC Quarantine option must also be enabled within the Event Log settings. When enabling NAC quarantine within a DLP Sensor, you must enable this in the CLI because it is a CLI-only command.

## Media Access Control (MAC) Address

MAC address logs provide information about MAC addresses that the FortiGate unit sees on the network as well as those removed from the network. These log messages are stored in the event log (as subtype network; you can view these log messages in **Log & Report > System Events**) and are, by default, disabled in the CLI. You can enable logging MAC addresses using the following command syntax:

```
config log setting
 set neighbor-event enable
end
```

When enabled, a new log message is recorded every time a MAC address entry is added to the ARP table, and also when a MAC address is removed as well. A MAC address log message is also recorded when MAC addresses are connected to the local switch, or from a FortiAP or FortiSwitch unit.

## Application control

Application control logs provide detailed information about the traffic that internet applications such as Skype are generating. The application control feature controls the flow of traffic from a specific application, and the FortiGate unit examines this traffic for signatures that the application generates.

The log messages that are recorded provide information such as the type of application being used (such as P2P software), and what type of action the FortiGate unit took. These log messages can also help you to determine the top ten applications that are being used on your network. This feature is called application control monitoring and you can view the information from a widget on the Executive Summary page.

The application control list that is used must have logging enabled within the list, as well as logging enabled within each application entry. Each application entry can also have packet logging enabled. Packet logging for application control records the packet when an application type is identified, similar to IPS packet logging.

Logging of application control activity can only be recorded when an application control list is applied to a firewall policy, regardless of whether or not logging is enabled within the application control list.

## Antivirus

Antivirus logs are recorded when, during the antivirus scanning process, the FortiGate unit finds a match within the antivirus profile, which includes the presence of a virus or grayware signature. Antivirus logs provide a way to understand what viruses are trying to get in, as well as additional information about the virus itself, without having to go to the FortiGuard Center and do a search for the detected virus. The link is provided within the log message itself.

These logs provide valuable information such as:

- the name of the detected virus
- the name of the oversized file or infected file
- the action the FortiGate unit took, for example, a file was blocked
- URL link to the FortiGuard Center which gives detailed information about the virus itself

The antivirus profile must have log settings enabled within it so that the FortiGate unit can record this activity, as well as having the antivirus profile applied to a firewall policy.

## Web Filter

Web filter logs record HTTP traffic activity. These log messages provide valuable and detailed information about this particular traffic activity on your network. Web filtering activity is important to log because it can inform you about:

- what types of web sites employees are accessing
- users attempting to access banned web sites and how often this occurs
- network congestion due to employees accessing the Internet at the same time
- web-based threats resulting from users visiting non-business-related web sites

Web Filter logs are an effective tool to help you determine if you need to update your web filtering settings within a web filter profile due to unforeseen threats or network congestion. These logs also inform you about web filtering quotas that have been configured for filtering HTTP traffic.

You must configure logging settings within the web filter profile and apply the filter to a firewall policy so that the FortiGate unit can record the activity.

## IPS (attack)

IPS logs, also referred to as attack logs, record attacks that occurred against your network. Attack logs contain detailed information about whether the FortiGate unit protected the network using anomaly-based defense settings or signature-based defense settings, as well as what the attack was.

The IPS or attack log file is especially useful because the log messages that are recorded contain a link to the FortiGuard Center, where you can find more information about the attack. This is similar to antivirus logs, where a link to the FortiGuard Center is provided as well that informs you of the virus that was detected by the FortiGate unit.

An IPS sensor with log settings enabled must be applied to a firewall policy so that the FortiGate unit can record the activity.

## Packet logs

When you enable packet logging within an IPS signature override or filter, the FortiGate unit examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

You can archive packets, but you must enable this option on the Log Settings page. If your log configuration includes multiple FortiAnalyzer units, packet logs are only sent to the primary (first) FortiAnalyzer unit. Sending packet logs to the other FortiAnalyzer units is not supported.

## Email filter

Email filter logs, also referred to as spam filter logs, record information regarding the content within email messages. For example, within an email filter profile, a match is found that finds the email message to be considered spam.

Email filter logs are recorded when the FortiGate unit finds a match within the email filter profile and logging settings are enabled within the profile.

If you are using a Banned Words List for email filtering, note that the filter pattern number is only recorded when the source email address contains a banned word.

---

## Archives (DLP)

Recording DLP logs for network use is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Archived logs are usually saved for historical use and can be accessed at any time. IPS packet logs can also be archived, within the Log Settings page.

You can start with the two default DLP sensors that have been configured specifically for archiving log data, Content\_Archive and Content\_Summary. They are available in **Security Profiles > Data Leak Prevention**. Content\_Archive provides full content archiving, while Content\_Summary provides summary archiving. For more information about how to configure DLP sensors, see the Security Features chapter of the FortiOS Handbook.

You must enable the archiving to record log archives. Logs are not archived unless enabled, regardless of whether or not the DLP sensor for archiving is applied to the firewall policy.

## Network scan

Network scan logs are recorded when a scheduled scan of the network occurs. These log messages provide detailed information about the network's vulnerabilities regarding software, as well as the discovery of any further vulnerabilities.

A scheduled scan must be configured and logging enabled within the Event Log settings, for the FortiGate unit to record these log messages.

## Log messages

Log messages are recorded by the FortiGate unit, giving you detailed information about the network activity. Each log message has a unique number that helps identify it, as well as containing fields; these fields, often called log fields, organize the information so that it can be easily extracted for reports.

These log fields are organized in such a way that they form two groups: the first group, made up of the log fields that come first, is called the log header. The log header contains general information, such as the unique log identification and date and time that indicates when the activity was recorded. The log body is the second group, and contains all the other information about the activity. There are no two log message bodies that are alike, however, there may be fields common to most log bodies, such as the `srcintf` or `identidix` log fields.

The log header also contains information about the log priority level which is indicated in the `level` field. The priority level indicates the immediacy and the possible repercussions of the logged action. For example, if the field contains 'alert', you need to take immediate action with regards to what occurred. There are six log priority levels.

The log severity level is the level at and above which the FortiGate unit records logs. The log severity level is defined by you when configuring the logging location. The FortiGate unit will log all messages at and above the priority level you select. For example, if you select Error, the unit will log only Error, Critical, Alert, and Emergency level messages.

### Log priority levels

| Levels                  | Description                                                    |
|-------------------------|----------------------------------------------------------------|
| <b>0 - Emergency</b>    | The system has become unstable.                                |
| <b>1 - Alert</b>        | Immediate action is required.                                  |
| <b>2 - Critical</b>     | Functionality is affected.                                     |
| <b>3 - Error</b>        | An error condition exists and functionality could be affected. |
| <b>4 - Warning</b>      | Functionality could be affected.                               |
| <b>5 - Notification</b> | Information about normal events.                               |
| <b>6 - Information</b>  | General information about system operations.                   |

The Debug priority level, not shown above, is rarely used. It is the lowest log priority level and usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly.

### Example log header fields

| Log header               |                                                                          |
|--------------------------|--------------------------------------------------------------------------|
| <b>date=(2010-08-03)</b> | The year, month and day of when the event occurred in yyyy-mm-dd format. |

| Log header                 |                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>time=(12:55:06)</b>     | The hour, minute and second of when the event occurred in the format hh:mm:ss.                                                                                                       |
| <b>log_id=(2457752353)</b> | A five or ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message. |
| <b>type=(dlp)</b>          | The section of system where the event occurred.                                                                                                                                      |
| <b>subtype=(dlp)</b>       | The subtype category of the log message.                                                                                                                                             |
| <b>level=(notice)</b>      | The priority level of the event. See the table above.                                                                                                                                |
| <b>vd=(root)</b>           | The name of the virtual domain where the action/event occurred in. If no virtual domains exist, this field always contains root.                                                     |

### Example log body fields

| Log body                     |                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>policyid=(1)</b>          | The ID number of the firewall policy that applies to the session or packet. Any policy that is automatically added by the FortiGate will have an index number of zero.                                                                                                                                                               |
| <b>identidx=(0)</b>          | The identity-based policy identification number. This field displays zero if the firewall policy does not use an identity-based policy; otherwise, it displays the number of the identity-based policy entry that the traffic matched. This number is not globally unique, it is only locally unique within a given firewall policy. |
| <b>sessionid=(311)</b>       | The serial number of the firewall session of which the event happened.                                                                                                                                                                                                                                                               |
| <b>srcip=(10.10.10.1)</b>    | The source IP address.                                                                                                                                                                                                                                                                                                               |
| <b>srcport=(1190)</b>        | The source port number.                                                                                                                                                                                                                                                                                                              |
| <b>srcintf=(internal)</b>    | The source interface name.                                                                                                                                                                                                                                                                                                           |
| <b>dstip=(192.168.1.122)</b> | The destination IP address.                                                                                                                                                                                                                                                                                                          |
| <b>dstport=(80)</b>          | The destination port number.                                                                                                                                                                                                                                                                                                         |
| <b>dstintf=(wan1)</b>        | The destination interface name.                                                                                                                                                                                                                                                                                                      |
| <b>service=(https)</b>       | The IP network service that applies to the session or packet. The services displayed correspond to the services configured in the firewall policy.                                                                                                                                                                                   |
| <b>status=(detected)</b>     | The action the FortiGate unit took.                                                                                                                                                                                                                                                                                                  |

| Log body                                                            |                                                                                                                                                                              |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hostname=(example.com)</b>                                       | The home page of the web site.                                                                                                                                               |
| <b>url=(/image/trees_pine_forest/)</b>                              | The URL address of the web page that the user was viewing.                                                                                                                   |
| <b>msg=(data leak detected (Data Leak Prevention Rule matched))</b> | Explains the FortiGate activity that was recorded. In this example, the data leak that was detected matched the rule, All-HTTP, in the DLP sensor.                           |
| <b>rulename=(All-HTTP)</b>                                          | The name of the DLP rule within the DLP sensor.                                                                                                                              |
| <b>action=(log-only)</b>                                            | The action that was specified within the rule. In some rules within sensors, you can specify content archiving. If no action type is specified, this field display log-only. |
| <b>severity=(1)</b>                                                 | The level of severity for that specific rule.                                                                                                                                |

Logs from other devices, such as the FortiAnalyzer unit and Syslog server, contain a slightly different log header. For example, when viewing FortiGate log messages on the FortiAnalyzer unit, the log header contains the following log fields when viewed in the Raw format:

```
itime=1302788921 date=20110401 time=09:04:23 devname=FG50BH3G09601792 device_
id=FG50BH3G09601792 log_id=0100022901 type=event subtype=system level=notice vd=root
```

The log body contains the rest of the information of the log message, and this information is unique to the log message itself.

For detailed information on all log messages, see the *FortiGate Log Message Reference*.

## Explanation of a debug log message

Debug log messages are only generated if the log severity level is set to Debug. The Debug severity level is the lowest log severity level and is rarely used. This severity level usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly. Debug log messages are generated by all types of FortiGate features.

The following is an example of a debug log message:

```
date=2010-01-25 time=17:25:54 logid=9300000000 type=webfilter subtype=urlfilter
level=debug msg="found in cache"
```

## Example of a Debug log message

| Debug log                |                                                                                |
|--------------------------|--------------------------------------------------------------------------------|
| <b>date=(2010-01-25)</b> | The year, month and day of when the event occurred in the format yyyy-mm-dd.   |
| <b>time=(17:25:54)</b>   | The hour, minute and second of when the event occurred in the format hh:mm:ss. |

| Debug log                     |                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>logid=(930000000000)</b>   | A ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message. |
| <b>type=(webfilter)</b>       | The section of system where the event occurred. There are eleven log types in FortiOS 4.0.                                                                                   |
| <b>subtype=(urlfilter)</b>    | The subtype of the log message. This represents a policy applied to the FortiGate feature in the firewall policy.                                                            |
| <b>level=(debug)</b>          | The priority level of the event. There are six priority levels to specify.                                                                                                   |
| <b>msg=(“found in cache”)</b> | Explains the activity or event that the FortiGate unit recorded.                                                                                                             |

## Viewing log messages and archives

Depending on the log device, you may be able to view logs within the web-based manager or CLI on the FortiGate unit. If you have configured a FortiAnalyzer unit, local hard disk, or system memory, you can view log messages from within the web-based manager or CLI. If you have configured either a Syslog or WebTrends server, you will not be able to view log messages from the web-based manager or CLI. There is also no support for viewing log messages stored on a FortiCloud server, from the FortiGate unit's web-based manager or CLI.

You do not have to view log messages from only the web-based manager. You can view log messages from the CLI as well, using the `execute log display` command. This command allows you to see specific log messages that you already configured within the `execute log filter` command. The `execute log filter` command configures what log messages you will see, how many log messages you can view at one time (a maximum of 1000 lines of log messages), and the type of log messages you can view. For more information about viewing log messages in the CLI, see "Viewing logs from the CLI".

There are two log viewing options in FortiOS: Format and Raw. The Raw format displays logs as they appear within the log file. You can view log messages in the Raw format using the CLI or a text editor, such as Notepad. Format is in a more human-readable format, and you can easily filter information when viewing log messages this way. The Format view is what you see when viewing logs in the web-based manager.

When you download the log messages from within the log message page (for example, **Log & Report > Forward Traffic**), you are downloading log messages in the Raw format.

## Viewing log messages in detail

From any log page, you can view detailed information about the log message in the log viewer table, located (by default) at the bottom of the page. Each page contains this log viewer table. The Log Viewer Table can contain the Archive tab, which allows you to see the archived version of the log message. The Archive tab only displays the archived log's details if archiving is enabled and logs are being archived by the FortiGate unit, but archived logs will also be recorded when using a FortiAnalyzer unit or the FortiCloud service.

When you are viewing traffic log messages, some of the categories (such as 'Application Name') have entries that can be selected to open a dialog box containing FortiGuard information about the entry. From within the dialog box, you can select the Reference link and go directly to the corresponding FortiGuard page, which contains additional information.

Viewing logs in Raw format allows you to view all log fields at once, as well as have a log file available regardless of whether you are archiving logs or not. You download the log file by selecting **Download Log**. The log file is named in the following format: <log\_type><log\_location><log\_date/time>.<log\_number>.log. For example, SystemEventLog-disk-2012-09-19T12\_13\_46.933949.log, which is an event log. The time period is the day and month of when the log was downloaded, not the time period of the log messages within the file itself.

## Quarantine

Within the Log & Report menu, you can view detailed information about each quarantined file. The information can either be sorted or filtered, depending on what you want to view.

You must enable quarantine settings within an antivirus profile and the destination must be configured in the CLI using the `config antivirus quarantine` command. The destination can be either a FortiAnalyzer unit or local disk.

Sort the files by file name, date, service, status, duplicate count (DC), or time to live (TTL). Filter the list to view only quarantined files with a specific status or from a specific service.

The file quarantine list displays the following information about each quarantined file.

### Quarantine page

Lists all files that are considered quarantined by the unit. On this page you can filter information so that only specific files are displayed on the page.

| GUI Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Source</b>        | Either <b>FortiAnalyzer</b> or <b>Local Disk</b> , depending where you configure to quarantined files to be stored.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Sort by</b>       | Sort the list. Choose from: <b>Status</b> , <b>Service</b> , <b>File Name</b> , <b>Date</b> , <b>TTL</b> , or <b>Duplicate Count</b> . Select <b>Apply</b> to complete the sort.                                                                                                                                                                                                                                                                                                   |
| <b>Filter</b>        | <p>Filter the list. Choose either <b>Status</b> (infected, blocked, or heuristics) or <b>Service</b> (IMAP, POP3, SMTP, FTP, HTTP, MM1, MM3, MM4, MM7, IM, or NNTP). Select <b>Apply</b> to complete the filtering. Heuristics mode is configurable through the CLI only.</p> <p>If your unit supports SSL content scanning and inspection Service can also be IMAPS, POP3S, SMTPS, or HTTPS. For more information, see the Security Features chapter of the FortiOS Handbook.</p> |
| <b>Apply</b>         | Select to apply the sorting and filtering selections to the list of quarantined files.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Delete</b>        | Select to delete the selected files.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Page Controls</b> | Use the controls to page through the list.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| GUI Item                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Remove All Entries</b> | Removes all quarantined files from the local hard disk.<br><br>This icon only appears when the files are quarantined to the hard disk.                                                                                                                                                                                                                                                                                                                        |
| <b>File Name</b>          | The file name of the quarantined file. When a file is quarantined, all spaces are removed from the file name, and a 32-bit checksum is performed on the file. The checksum appears in the replacement message but not in the quarantined file. The file is stored on the FortiGate hard disk with the following naming convention:<br><br><32bit_CRC>.<processed_filename><br><br>For example, a file named Over Size.exe is stored as 3fc155d2.oversize.exe. |
| <b>Date</b>               | The date and time the file was quarantined, in the format dd/mm/yyyy hh:mm. This value indicates the time that the first file was quarantined if duplicates are quarantined.                                                                                                                                                                                                                                                                                  |
| <b>Service</b>            | The service from which the file was quarantined (HTTP, FTP, IMAP, POP3, SMTP, MM1, MM3, MM4, MM7, IM, NNTP, IMAPS, POP3S, SMTPS, or HTTPS).                                                                                                                                                                                                                                                                                                                   |
| <b>Status</b>             | The reason the file was quarantined: <b>infected</b> , <b>heuristics</b> , or <b>blocked</b> .                                                                                                                                                                                                                                                                                                                                                                |
| <b>Status Description</b> | Specific information related to the status, for example, "File is infected with "W32/Klez.h"" or "File was stopped by file block pattern."                                                                                                                                                                                                                                                                                                                    |
| <b>DC</b>                 | Duplicate count. A count of how many duplicates of the same file were quarantined. A rapidly increasing number can indicate a virus outbreak.                                                                                                                                                                                                                                                                                                                 |
| <b>TTL</b>                | Time to live in the format hh:mm. When the TTL elapses, the FortiGate unit labels the file as EXP under the TTL heading. In the case of duplicate files, each duplicate found refreshes the TTL.<br><br>The TTL information is not available if the files are quarantined on a FortiAnalyzer unit.                                                                                                                                                            |
| <b>Upload status</b>      | <b>Y</b> indicates the file has been uploaded to Fortinet for analysis, <b>N</b> indicates the file has not been uploaded.<br><br>This option is available only if the FortiGate unit has a local hard disk.                                                                                                                                                                                                                                                  |
| <b>Download</b>           | Select to download the corresponding file in its original format.<br><br>This option is available only if the FortiGate unit has a local hard disk.                                                                                                                                                                                                                                                                                                           |
| <b>Submit</b>             | Select to upload a suspicious file to Fortinet for analysis.<br><br>This option is available only if the FortiGate unit has a local hard disk.                                                                                                                                                                                                                                                                                                                |

## Customizing the display of log messages on the web-based manager

Customizing log messages on the web-based manager allows you to remove or add columns from the page and filter the information that appears. For example, you can view only log messages that appeared on December 4, between the hours of 8:00 and 8:30 am.

1. Select the submenu in **Log & Report** in which you want to customize the display of log messages, such as **Log & Report > Forward Traffic**.
2. Right click on the title bar at the top of any column, and uncheck a column title such as **Date/Time** to remove it from the interface. Check other columns to add them to the interface. When you are finished, click outside the menu and the page will refresh with the new column settings in place.
3. Choose a column you'd like to filter, and select the funnel icon next to the title of the column. For example, select the funnel in the Src (Source) column. In the text field, enter the source IP address 1.1.1.1 and then select the check box beside **NOT**.  
This filters out the all log messages that have the 1.1.1.1 source IP address in the source IP log field, such as the ones generated when running log tests in the CLI.
4. Select **OK** to save the customize settings, and then view the log messages on the page.  
Log messages that originate from the 1.1.1.1 source address will no longer appear in the list.

## How to download log messages and view them from on a computer

After recording some activity, you can download log messages to view them from a computer. This is can be very useful when in a remote location, or if you want to view log messages at your convenience, or to view packet logs or traffic logs.

1. In Log & Report, select the submenu that you want to download log messages from.  
For example, **Log & Report > Forward Traffic**.
2. Select the **Download Log** option and save the log file to your computer.  
The log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.
3. Open a text editor such as Notepad, open the log file, and then scroll to view all the log messages.  
You can easily search or scroll through the logs to see the information that is available.

## Log files and types

As the log messages are being recorded, log messages are also being put into different log files. The log file contains the log messages that belong to that log type, for example, traffic log messages are put in the traffic log file.

When downloading the log file from within **Log & Report**, the file name indicates the log type and the device on which it is stored, as well as the date, time, and a unique id for that log.

This name is in the format <logtype> - <logdevice> - <date> T <time> . <id>.log.

For example, AntiVirusLog-disk-2012-09-13T11\_07\_57.922495.log.

Below, each of the different log files are explained. Traffic and Event logs come in multiple types, but all contain the base type such as 'Event' in the filename.

## Log Types based on network traffic

| Log Type                    | Description                                                                                                                                                                                                                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Traffic</b>              | The traffic logs records all traffic to and through the FortiGate interface. Different categories monitor different kinds of traffic, whether it be forward, local, or sniffer.                                                                                                                 |
| <b>Event</b>                | The event logs record management and activity events within the device in particular areas: System, Router, VPN, User, Endpoint, HA, WAN Opt./Cache, and WiFi. For example, when an administrator logs in or logs out of the web-based manager, it is logged both in System and in User events. |
| <b>Antivirus</b>            | The antivirus log records virus incidents in Web, FTP, and email traffic.                                                                                                                                                                                                                       |
| <b>Web Filter</b>           | The web filter log records HTTP FortiGate log rating errors including web content blocking actions that the FortiGate unit performs.                                                                                                                                                            |
| <b>Application Control</b>  | The application log records application usage, monitoring or blocking as configured in the security profiles.                                                                                                                                                                                   |
| <b>Intrusion</b>            | The intrusion log records attacks that are detected and prevented by the FortiGate unit.                                                                                                                                                                                                        |
| <b>Email Filter</b>         | The email filter log records blocking of email address patterns and content in SMTP, IMAP, and POP3 traffic.                                                                                                                                                                                    |
| <b>Vulnerability Scan</b>   | The Vulnerability Scan (Netscan) log records vulnerabilities found during the scanning of the network.                                                                                                                                                                                          |
| <b>Data Leak Prevention</b> | The Data Leak Prevention log records log data that is considered sensitive and that should not be made public. This log also records data that a company does not want entering their network.                                                                                                  |
| <b>VoIP</b>                 | The VoIP log records VoIP traffic and messages. It only appears if VoIP is enabled on the Administrator Settings page.                                                                                                                                                                          |

## Log database and datasets

The log database, also known as the SQL log database, is used to store logs on FortiGate units that have a built-in hard disk. The log database uses Structured Query Language (SQL), specifically it uses SQLite which is an embedded Relational Database Management System (RDBMS).

If you have disabled SQL logging and have factory defaults on the FortiGate unit, and then you upgrade the firmware, the upgrade will automatically disable SQL logging. When this occurs, you must re-enable SQL logging manually.

The FortiGate unit creates a database table for each log type, when log data is recorded. If the FortiGate unit is not recording log data, it does not create log tables for that device.

If you want to view the size of the database, as well as the log database table entries, use the `get report sql status` command. This command displays the amount of free space that is available as well as the first and last log database entry time and date.

The output of the `get report sql status` command contains information similar to the following:

```
Database size: 294912
Free size in database: 0
Database Page Size: 8192
Entry number:
Event: 49
Traffic: 370
Attack: 2
AntiVirus: 4
WebFilter: 254
AntiSpam: 2
Netscan: 18
Total: 699
First entry time: 2012-09-10 11:41:02
Last entry time: 2012-09-13 02:59:59
```

The log database is not only used to store logs, but also used to extract the information for reports. Reports are built from datasets, which are SQL statements that tell the FortiGate unit how to extract the information from the database. You can create your own datasets; however, SQL knowledge is required. Default datasets are available for reports.

## Notifications about network activity

Alert email messages provide notification about activities or events logged. These email messages also provide notification about log severities that are recorded, such as a critical or emergency.

You can send alert email messages to up to three email addresses. Alert messages are also logged and can be viewed from the Event Log menu, in the System Event log file.

You can use the alert email feature to monitor logs for log messages, and to send email notification about a specific activity or event logged. For example, if you require notification about administrators logging in and out, you can configure an alert email that is sent whenever an administrator logs in and out. You can also base alert email messages on the severity levels of the logs.

Before configuring alert email, you must configure at least one DNS server if you are configuring with an Fully Qualified Domain Server (FQDN). The FortiGate unit uses the SMTP server name to connect to the mail server, and must look up this name on your DNS server. You can also specify an IP address.

The default minimum log severity level is Alert. If the FortiGate unit collects more than one log message before an interval is reached, the FortiGate unit combines the messages and sends out one alert email.

## How to configure email notifications

The following explains how to configure an alert email notification for IPsec tunnel errors, firewall authentication failure, configuration changes and FortiGuard license expiry.

1. In **System > Advanced**, under **Email Service**, configure the SMTP server.

The SMTP server settings allow the FortiGate unit to know exactly where the email will be sent from, as well as who to send it to. The SMTP server must be a server that does not support SSL/TLS connections; if the SMTP server does, the alert email configuration will not work. The FortiGate unit does not currently support SSL/TLS

connections for SMTP servers.

2. In **Log & Report > Alert E-mail**, enter the source email in the Email From field, and up to three target addresses in the Email To fields.
3. Below the email entry, you can configure the email responses. By default, the **Send alert email for the following** is enabled. Select the check boxes beside **IPsec tunnel errors**, **Configuration changes** and **Firewall authentication failure**.

These alerts will be sent to the email address specified when the trigger occurs. For example, a user attempts to connect to the branch office of the company but cannot; the FortiGate unit detects an IPsec tunnel error, records the event, and then sends the notice to the email address specified in the SMTP server settings.

4. Select **FortiGuard license expiry time**: and then enter 10 so that the email notification will be sent ten days prior to the FortiGuard license expiration.

You can choose up to 100 days prior to when the license will expire. The default time is 15 days. By using this alert email notification, you can easily know when to send an re-registration request long before the expiry.

## Log devices

The FortiGate unit supports a variety of log devices, including the FortiCloud service and FortiAnalyzer units. This provides greater flexibility not only when choosing a log device, but also when your logging requirements need updating.

When you have developed a plan that meets your logging needs and requirements, you need to select the log device that is appropriate for that plan. A log device must be able to store all the logs you need, and if you require archiving those logs, you must consider what log devices support this option.

During this process of deciding what log device meets your needs and requirements, you must also figure out how to provide a backup solution in the event the log device that the FortiGate unit is sending logs to has become unavailable. A backup solution should be an important part of your log setup because it helps you to maintain all logs and prevents lost logs, or logs that are not sent to the log device. For example, a daily backup of log files to the FortiAnalyzer unit occurs at 5 pm.

Log devices provide a central location for storing logs recorded by the FortiGate unit. The following are log devices that the FortiGate unit supports:

- FortiGate system memory
- Hard disk or AMC
- SQL database (for FortiGate units that have a hard disk)
- FortiAnalyzer unit
- FortiCloud service
- Syslog server

These log devices, except for the FortiGate system memory and local hard disk, can also be used as a backup solution. For example, you can configure logging to the FortiGate unit's local disk, but also configure logging to a FortiCloud server and archive logs to both the FortiCloud server and a FortiAnalyzer unit.

If you are formatting a disk that contains more than just logs, all information on the disk will be lost.

---

## FortiGate unit's system memory and hard disk

The FortiGate unit's system memory and hard disk can store all log types, including log archives and traffic logs. Traffic logs and log archives are larger files, and need a lot of room when being logged by the FortiGate unit.

When the system memory is full, the FortiGate unit overwrites the oldest messages, and all log messages stored in memory are cleared when the FortiGate unit restarts. By default, logging to memory is enabled. This means that most of the time you will only need to modify the default settings to your network logging requirements. Real-time logging occurs whenever memory logging is enabled, and is enabled by default. Real-time logging means that the activity is being recorded as it happens.

All FortiGate units 100D and larger are capable of disk logging, but it is disabled by default, as it is not recommended. For flash memory-based units, constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. For hard-disk units, it can affect performance under heavy strain. Therefore, disk logging must be manually enabled in the CLI under `config log disk setting` to appear in the interface at all.

Models without a hard disk are not recommended for disk logging. For all units, disk logging must be enabled in the CLI. For some low-end and older models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

Local disk or memory logging is not required for you to configure logging to a FortiAnalyzer unit.

If you are registered with the FortiCloud service, your unit will log both locally and to the service by default. In order to configure the rate and time of uploads to the service, you must register a contract account for the FortiCloud service, which will also grant you additional space.

## FortiAnalyzer unit

The FortiAnalyzer unit can log all FortiGate features, which includes log archives. You can also configure the FortiGate unit to upload logs to the FortiAnalyzer unit at a scheduled time.

Encryption of the logs is supported by default and logs are sent using SSL VPN. When the FortiAnalyzer and FortiGate units have SSL encryption, both must choose a setting for the `enc-algorithm` command (CLI) for encryption to take place. By default, this is enabled and the default setting is a SSL communication with high and medium encryption algorithms. The setting that you choose must be the same for both.

FortiGate units can support logging to multiple FortiAnalyzer units. This logging solution is a backup redundancy solution, since logs are sent to all three units and whenever one of the FortiAnalyzer units fails, the others still carry on storing logs.

If you are using evaluation software FortiGate and FortiAnalyzer-VM images, you will only be able to use low-level encryption.

The FortiGate unit can also connect to a FortiAnalyzer unit using Automatic Discovery. Automatic Discovery is a method of establishing a connection to a FortiAnalyzer unit by using the FortiGate unit to find a FortiAnalyzer unit on the network. The Fortinet Discovery Protocol (FDP) is used to locate the FortiAnalyzer unit. Both the FortiGate and FortiAnalyzer units must be on the same subnet to use FDP, and they must also be able to connect using UDP.

When you enable automatic discovery in the CLI, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers a

FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

## Syslog server

A Syslog server is a remote computer running syslog software. Syslog is a standard for forwarding log messages in an IP network, and can be used when considering a log backup solution for your network logging requirements. Logs that are generated in real-time are sent to the syslog server in real time with no queueing, so it can be an ideal solution for comprehensive logging, or collecting logs for later systematic analysis.

FortiGate units support the reliable syslog feature, which is based on RFC 3195. Reliable syslog logging uses TCP, which ensures that connections are set up, including that packets are transmitted.

There are several profiles available for reliable syslog, but only the RAW profile is currently supported on the FortiGate units. The RAW profile is designed to provide a high-performance, low-impact footprint using essentially the same format as the existing UDP-based syslog service. The reliable syslog feature is available on FortiGate units running FortiOS 4.0 MR1 and higher.

When enabling the reliable syslog (available only in the CLI), TCP is used. The feature is disabled by default, and when enabled, the FortiGate unit automatically changes the port number to TCP 601. This is based on RFC 3195. The default port for syslog is port 514.

If you are using the local hard disk on a device for WAN Optimization, it will not prevent you from logging to remote FortiAnalyzer devices or Syslog servers. Some models have two hard disks, allowing both local logging and Wan Opt.

---

If you have Virtual Domains configured, each VDOM may only be assigned one FortiAnalyzer device and one Syslog server, by overriding the global configuration. The root VDOM is not limited in this way.

---

## How to choose a log device for your network topology

When planning the log requirements, you must also consider your network's topology and whether archiving is required, such as if there is a legal requirement to keep a historical record of network activity. The following explains what steps to take when choosing a log device for your specific network topology.

### 1. What is the scope of your network topology?

If it is a SOHO/SMB network, then logging to the FortiGate unit's local hard disk or the default FortiCloud service would be efficient. If the network topology is a large enterprise, you will need FortiAnalyzer units, a FortiCloud contract, Syslog servers, or any combination.

### 2. Is archiving required?

If the network activity that is being logged needs to be archived, then, depending on your network topology, you would choose a FortiAnalyzer unit. FortiAnalyzer units store archives in the same way that FortiGate units do, but are able to store large amounts of logs and archives.

### 3. When troubleshooting, you may want to log a larger amount of traffic; how much storage space will you need?

Logs can be configured to roll, which is similar to zipping a file; this will lower the space requirements needed to contain them. You can also download logs from the FortiGate unit and save them on a server or on a computer to view and access later, to prevent them from piling up and being overwritten. If you're regularly logging large amounts of traffic, you should consider a FortiAnalyzer or FortiCloud account .

**4. Should I invest in a log device that can grow as my network grows?**

All networks grow, so investing in a device that can grow with your network and that can be expanded is a good investment. For example, if you currently have a SOHO/SMB topology, but see growth already starting, a FortiAnalyzer unit would be best. A FortiAnalyzer unit provides ample storage space, and you can add two more FortiAnalyzer units to access additional storage and create a redundancy log backup solution.

## How to create a backup solution for logging

The following helps to explain how to create a log backup solution for a small network topology. This example has one FortiAnalyzer unit and a subscription to the FortiCloud Service.

### Example of an integrated FortiAnalyzer unit and Syslog servers in a network

1. Log in to the CLI and modify what features will be logged to the FortiAnalyzer unit as well as the settings to the default log device, the FortiGate unit's hard drive.  
By default, the FortiGate unit logs to either the system memory or hard drive, whichever is available on the FortiGate unit. Low-end FortiGate units may have logging disabled by default.
2. In the CLI, use the `config log fortianalyzer setting` command to configure logging to the FortiAnalyzer unit.  
You can only configure log settings for the FortiAnalyzer unit in the CLI. Configuring to upload logs to a FortiAnalyzer unit can be configured in both the CLI and web-based manager.
3. In the CLI, configure the settings for the Syslog server; also enable reliable syslog as well.  
Reliable syslog verifies that logs are sent to the syslog server. When you enable this setting, the default port becomes port 601.

## Reports

Reports provide a clear, concise overview of what is happening on your network based on log data, and can be customized to serve different purposes. There are three types of reports supported by the FortiGate: FortiOS Reports, FortiCloud Reports, and FortiAnalyzer Reports.

FortiOS Reports are generated and configured on the FortiGate unit itself, FortiCloud Reports are created and configured on the FortiCloud site and mirrored to the connected FortiGate for viewing, and FortiAnalyzer reports are created and configured on a FortiAnalyzer unit. For more information about those reports, see the FortiAnalyzer Administration Guide.

In order to create FortiOS Reports on a device, disk logging must be enabled. Not all devices are capable of disk logging; check the Feature Matrix to see if your unit has a hard disk. Once disk logging has been enabled, Local Reports can then be enabled in **System > Feature Visibility** in order to view and edit reports.

### What are FortiOS reports?

FortiOS reports are created from logs stored on the FortiGate unit's hard drive. These reports, generated by the FortiGate unit itself, provide a central overview of traffic and security features on the FortiGate. A default FortiOS report, called the FortiGate Security Feature Daily Activity Report, is available for you to use or modify to your requirements. The default report compiles security feature activity from various security-related logs, such as virus and attack logs. You can quickly and easily create your own report from within the management interface.

### What you can do with the default FortiOS report

On the **Log & Report > Local Reports** page, you can set the frequency and timing of auto-generated reports.

You can select **Run Now** on the **Local Reports** page to immediately create a report with the current layout and design. More complex reports may take longer to generate. After generating a report, you can view it by selecting it from the list below **Run Now**.

Historical reports will be marked as 'Scheduled' if created automatically, or 'On Demand' if created by selecting **Run Now**.

### What are FortiCloud reports?

FortiCloud reports are created from logs stored on the FortiCloud log management service. An active FortiCloud Service Subscription is required in order to view, configure, or use these reports. They are generated by FortiCloud according to a schedule you set, and then mirrored to the FortiGate interface and can be viewed at **Log & Report > FortiCloud Reports**, which may not appear in the interface until a report is created. If you wish to configure the report design or structure, you will have to do so from the FortiCloud portal website.

See the FortiCloud Administration Guide for more information about using and configuring FortiCloud reports.

## Best Practices: Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- what FortiGate activities you want and/or need logged (for example, security features)
- the logging device best suited for your network structure
- if you want or require archiving of log files
- ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

1. Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
2. Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
3. If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the Applications FortiView dashboard, or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
4. Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

## Logging and reporting for small networks

This section explains how to configure the FortiGate unit for logging and reporting in a small office or SOHO/SMB network. To properly configure this type of network, you will be modifying the default log settings, as well as the default FortiOS report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

### Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

#### Modifying the FortiGate unit's system memory default settings

When the FortiGate unit's default log device is its system memory, the following is modified for a small network topology. The following is an example of how to modify these default settings.

##### To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
 set status enable
end
```

3. The following example command syntax modifies which FortiGate features that are enabled for logging:

```
config log memory filter
 set forward-traffic enable
 set local-traffic enable
 set sniffer-traffic enable
 set anomaly enable
 set voip disable
 set multicast-traffic enable
 set dns enable
end
```

#### Modifying the FortiGate unit's hard disk default settings

When the FortiGate unit's default log device is its hard disk, you need to modify those settings to your network's logging needs so that you can effectively log what you want logged. The following is an example of how to modify these default settings.

### To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
 set ips-archive disable
 set status enable
 set max-log-file-size 1000
 set storage FLASH
 set log-quota 100
 set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log eventfilter
 set event enable
 set system enable
 set vpn disable
 set user enable
 set router disable
 set wan-opt disable
end
```

### Testing sending logs to the log device

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

### To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
```

```
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.  
You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

## Configuring the backup solution

A backup solution provides a way to ensure logs are not lost. The following backup solution explains logging to a FortiCloud server and uploading logs to a FortiAnalyzer unit. With this backup solution, there can be three simultaneous storage locations for logs, the first being the FortiGate unit itself, the FortiAnalyzer unit and then the FortiCloud server.

### Configuring logging to a FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how these settings are configured for a network’s log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

#### To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the **License Information** widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.
5. Under the Logging and Archiving header, you can select your desired upload time.

With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

### Configuring uploading logs to the FortiAnalyzer unit

The logs will be uploaded to the FortiAnalyzer unit at a scheduled time. The following is an example of how to upload logs to a FortiAnalyzer unit.

#### To upload logs to a FortiAnalyzer unit

1. Go to **Log & Report > Log Settings**.
2. In the **Remote Logging and Archiving** section, select the check box beside **Send Logs to FortiAnalyzer/FortiManager**.
3. Select **FortiAnalyzer (Daily at 00:00)**.
4. Enter the FortiAnalyzer unit’s IP address in the **IP Address** field.
5. To configure the daily upload time, open the CLI.
6. Enter the following to configure when the upload occurs, and the time when the unit uploads the logs:

```
config log fortianalyzer setting
 set upload-interval {daily | weekly | monthly}
 set upload-time <hh:mm>
```

end

7. To change the upload time, in the web-based manager, select **Change** beside the upload time period, and then make the changes in the Upload Schedule window. Select **OK**.

### Testing uploading logs to a FortiAnalyzer unit

You should test that the FortiGate unit can upload logs to the FortiAnalyzer unit, so that the settings are configured properly.

#### To test the FortiAnalyzer upload settings

1. Go to **Log & Report > Log Settings**.
2. In the **Logging and Archiving** section, under **Send Logs to FortiAnalyzer/FortiManager**, change the time to the current time by selecting **Change**.  
For example, the current time is 11:10 am, so **Change** now has the time 11:10.
3. Select **OK**.

The logs will be immediately sent to the FortiAnalyzer unit, and will be available to view from within the FortiAnalyzer's interface.

## Logging and reporting for large networks

This section explains how to configure the FortiGate unit for logging and reporting in a larger network, such as an enterprise network. To set up this type of network, you are modifying the default log settings, and you are also modifying the default report.

The following procedures are examples and can be used to help you when configuring your own network's log topology.

Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

### Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled and well as logging to either the FortiGate unit's system memory or hard disk, depending on the model.

#### Modifying multiple FortiGate units' system memory default settings

When the FortiGate unit's default log device is its system memory, you can modify it to fit your log network topology. In this topic, the following is an example of how you can modify these default settings.

##### To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
 set status enable
end
```
3. Enter the following command syntax to modify the FortiGate features that are enabled for logging:

```
config log memory filter
 set forward-traffic enable
 set local-traffic enable
 set sniffer-traffic enable
 set anomaly enable
 set voip enable
 set multicast-traffic enable
 set dns enable
end
```
4. Repeat steps 2 and 3 for the other FortiGate units.
5. Test the modified settings using the procedure below.

#### Modifying multiple FortiGate units' hard disk default log settings

You will have to modify each FortiGate unit's hard disk default log settings. The following is an example of how to modify these default settings.

### To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
 set ips-archive disable
 set status enable
 set max-log-file-size 1000
 set storage Internal
 set log-quota 100
 set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log eventfilter
 set event enable
 set system enable
 set vpn enable
 set user enable
 set router disable
 set wan-opt disable
end
```

4. Repeat the steps 2 to 4 for the other FortiGate units.
5. Test the modified settings using the procedure below.

### Testing the modified log settings

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

### To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
```

```

generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a URL block message with level - warning

```

2. In the web-based interface, go to **Log & Report > System Events**, and view the logs to see some of the recently generated test log messages.

You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

## Configuring the backup solution

Even though you are logging to multiple FortiAnalyzer units, this is more of a redundancy solution rather than a complete backup solution in this example.

The multiple FortiAnalyzer units act similar to a HA cluster, since if one FortiAnalyzer unit fails, the others continue storing the logs they receive. In a backup solution, the logs are backed up to another secure location if something happens to the log device.

A good alternate or redundant option is the FortiCloud service, which can provide secure online logging and management for multiple devices.

## Configuring logging to multiple FortiAnalyzer units

The following example shows how to configure logging to multiple FortiAnalyzer units. Configuring multiple FortiAnalyzer units is quick and easy; however, you can only configure up to three FortiAnalyzer units per FortiGate unit.

### To configure multiple FortiAnalyzer units

1. In the CLI, enter the following command syntax to configure the first FortiAnalyzer unit:

```

config log fortianalyzer setting
 set status enable
 set server 172.20.120.22
 set max-buffer-size 1000
 set buffer-max-send 2000
 set address-mode static
 set conn-timeout 100
 set monitor-keepalive-period 120
 set monitor-failure-retry-period 2000
end

```

2. Disable the features that you do not want logged, using the following example command syntax. You can view the CLI Reference to see what commands are available.

```

config log fortianalyzer filter
 set forward-traffic (enable | disable)
 ...
end

```

3. Enter the following commands for the second FortiAnalyzer unit:

```

config log fortianalyzer2 setting
 set status enable

```

```
set server 172.20.120.23
set max-buffer-size 1000
set buffer-max-send 2000
set address-mode static
set conn-timeout 100
set monitor-keepalive-period 120
set monitor-failure-retry-period 2000
end
```

4. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer2 filter
set event (enable | disable)
...
end
```

5. Enter the following commands for the last FortiAnalyzer unit:

```
config log fortianalyzer3 setting
set status enable
set server 172.20.120.23
set max-buffer-size 1000
set buffer-max-send 2000
set address-mode static
set conn-timeout 100
set monitor-keepalive-period 120
set monitor-failure-retry-period 2000
end
```

6. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer3 filter
set voip (enable | disable)
...
end
```

7. Test the configuration by using the procedure, [“Testing the modified log settings”](#).
8. On the other FortiGate units, configure steps 1 through 6, ensuring that logs are being sent to the FortiAnalyzer units.

## Configuring logging to the FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network’s log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

### To configure logging to the FortiCloud server

1. Go to **Dashboard** and click **Login** next to **FortiCloud** in the License Information widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Settings**.
5. Under the **Remote Logging and Archiving** header, you can select your desired upload time.

6. With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

## Advanced logging

This section explains how to configure other log features within your existing log configuration. You may want to include other log features after initially configuring the log topology because the network has either outgrown the initial configuration, or you want to add additional features that will help your network's logging requirements.

The following topics are included in this section:

- [Log backup and restore tools](#)
- [Configuring logging to multiple Syslog servers](#)
- [Using Automatic Discovery to connect to a FortiAnalyzer unit](#)
- [Activating a FortiCloud account for logging purposes](#)
- [Viewing log storage space](#)
- [Customizing and filtering log messages](#)
- [Viewing logs from the CLI](#)
- [Configuring NAC quarantine logging](#)
- [Logging local-in policies](#)
- [Tracking specific search phrases in reports](#)
- [Advanced logging](#)

### Log backup and restore tools

Local disk logs can now be backed up and restored to local files, using CLI commands:

```
execute log backup <filename>
execute log restore <filename>
```

Restoring logs will wipe the current log and report content off the disk.

Logs can also now be exported to a USB storage device, as LZ4 compressed files, from both CLI and GUI. When you insert a USB drive into the FortiGate's USB port, the USB menu will appear in the GUI. The menu shows the amount of storage on the USB disk, and the log file size, and you can select **Copy to USB** to copy the log data to the drive.

### Configuring logging to multiple Syslog servers

A single remote Syslog server can be configured in the GUI, in **Log & Report > Log Settings**, but for a larger network, you will have to configure it in the CLI.

When configuring multiple Syslog servers (or one Syslog server), you can configure reliable delivery of log messages from the Syslog server. Configuring of reliable delivery is available only in the CLI.

If VDOMs are enabled, you can configure separate FortiAnalyzer unit or Syslog server for each VDOM.

**To enable logging to multiple Syslog servers:**

1. Log in to the CLI.
2. Enter the following commands:

```
config log syslogd setting
```

```

set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end

```

**3. Enter the following commands to configure the second Syslog server:**

```

config log syslogd2 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end

```

**4. Enter the following commands to configure the third Syslog server:**

```

config log syslogd3 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end

```

**5. Enter the following commands to configure the fourth Syslog server:**

```

config log syslogd4 setting
set csv {disable | enable}
set facility <facility_name>
set port <port_integer>
set reliable {disable | enable}
set server <ip_address>
set status {disable | enable}
end

```

Most FortiGate features are, by default, enabled for logging. You can disable individual FortiGate features you do not want the Syslog server to record, as in this example:

```

config log syslogd filter
set local-traffic {enable | disable}
set severity {alert | critical | debug | emergency | error | information |
notification | warning}
end

```

## Using Automatic Discovery to connect to a FortiAnalyzer unit

Automatic Discovery can be used if the FortiAnalyzer unit is on the same network.

### To connect using automatic discovery

1. Log in to the CLI.
2. Enter the following command syntax:

```

config log fortianalyzer setting
set status enable

```

```
set server <ip_address>
set gui-display enable
set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic. For more information about how to enable the interface to also carry traffic when using the automatic discovery feature, see the Fortinet Knowledge Base article, [Fortinet Discovery Protocol in Transparent mode](#).

The FortiGate unit searches within the same subnet for a response from any available FortiAnalyzer units.

---

## Activating a FortiCloud account for logging purposes

When you subscribe to FortiCloud, you can configure to send logs to the FortiCloud server. The account activation can be done within the web-based manager, from the **License Information** widget located in **Dashboard**.

From this widget, you can easily create a new account, or log in to the existing account. From within the License Information widget, after the account is activated, you can go directly to the FortiCloud web portal, or log out of the service if you are already logged in.

### To activate a FortiCloud account for logging purposes:

The following assumes that you are already at **Dashboard** and that you have located the License Information widget.

1. In the License Information widget, select **Activate** in the **FortiCloud** section.  
The Registration window appears. From this window, you create the login credentials that you will use to access the account.
2. Select **Create Account** and enter then information for the login credentials.  
After entering the login credentials, you are automatically logged in to your FortiCloud account.
3. Check that the account has been activated by viewing the account status from the License Information widget.

If you need more space, you can subscribe to the 200Gb FortiCloud service by selecting **Upgrade** in the **FortiCloud** section of the widget.

## Viewing log storage space

The **Log & Report > Log Settings** GUI page displays two charts to visualize disk space: Disk Usage, which is a pie-chart illustrating the Free/Used space on the internal hard drive, and Historical Disk Usage, which displays the volume of disk logging activity over time. These charts may not be visible if disk logging is disabled.

The `diag sys logdisk usage` command allows you to view detailed information about how much space is currently being used for logs. This is useful when you see a high percentage, such as 92 percent for the disk's capacity. The FortiGate unit uses only 75 percent of the available disk capacity to avoid a high storage amount so when there is a high percentage, it refers to the percentage of the 75 percent that is available. For example, 92 percent of the 75 percent is available.

The following is an example of what you may see when you use `diag sys logdisk usage` command on a unit with no VDOMs configured:

```
diag sys logdisk usage
```

The following appears:

```
Total HD usage: 176MB/3011 MB
Total HD logging space: 22583MB
Total HD logging space for each vdom: 22583MB
HD logging space usage for vdom "root": 30MB/22583MB
```

## Customizing and filtering log messages

When viewing log messages, you may want to customize and filter the information that you are seeing in the Log & Report menu (for example, Log & Report > Traffic Log > Forward Traffic). Filtering and customizing the display provides a way to view specific log information without scrolling through pages of log messages to find the information.

Customizing log messages is the process of removing or adding columns to the log display page, allowing you to view certain desired information. The most columns represent the fields from within a log message, for example, the user column represents the user field, as well as additional information. If you want to reset the customized columns on the page back to their defaults, you need to select **Reset All Columns** within the column title right-click menu.

Filtering information is similar to customizing, however, filtering allows you to enter specific information that indicates what should appear on the page. For example, including only log messages that appeared on February 24, between the hours of 8:00 and 8:30 am.

### To customize and filter log messages

The following is an example that displays all traffic log messages that originate from the source IP address 172.20.120.24, as well as displaying only the columns:

- OS Name
- OS Version
- Policy ID
- Src (Source IP)

The following assumes that you are already on the page of the log messages you want to customize and filter. In this example, the log messages that we are customizing and filtering are in **Log & Report > Forward Traffic**.

1. On the Forward Traffic page, right click anywhere on a column title.
2. Right click on a column title, and mouse over **Column Settings** to open the list.
3. Select each checkmarked title to uncheck it and remove them all from the displayed columns.
4. Scroll down to the list of unchecked fields and select 'OS Name', 'OS Version', 'Policy ID', and 'Src' to add checkmarks next to them.
5. Click outside the menu, and wait for the page to refresh with the new settings in place.
6. Select the funnel icon next to the word Src in the title bar of the Src column.
7. Enter the IP you want displayed (in this example, 172.20.120.24) in the text box.
8. Click **Apply**, and wait for the page to reload.

## Viewing logs from the CLI

You can easily view log messages from within the CLI. In this example, we are viewing DLP log messages.

1. Log in to the CLI and then enter the following to configure the display of the DLP log messages.

```
execute log filter category 9
```

```
execute log filter start-line 1
execute log filter view-lines 20
```

The customized display of log messages in the CLI is similar to how you customize the display of log messages in the web-based manager. For example, `category 9` is the DLP log messages, and the `start-line` is the first line in the log database table for DLP log messages, and there will be 20 lines (`view-lines 20`) that will display.

2. Enter the following to view the log messages:

```
execute log display
```

The following appears below `execute log display`:

```
600 logs found
20 logs returned
```

along with the 20 DLP log messages.

## Configuring NAC quarantine logging

NAC quarantine log messages provide information about what was banned and quarantined by a Antivirus profile. The following explains how to configure NAC quarantine logging and enable it on a policy. This procedure assumes the Antivirus profile is already in place.

### To configure NAC quarantine logging

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy that you want to apply the Antivirus profile to, and then select **Edit**.
3. Within the Security Profiles section, enable **Antivirus** and then select the profile from the drop-down list.
4. Select **OK**.
5. Log in to the CLI.
6. Enter the following to enable NAC quarantine in the DLP sensor:

```
config antivirus profile
edit <profile_name>
config nac-quar log enable
end
```

## Logging local-in policies

Local-in security policies are policies that control the flow of internal traffic, and can be used to broaden or restrict an administrator's access privileges. These local-in policies can also be configured to log traffic and activity that the policies control.

You can enable logging of local-in policies in the CLI, with the following commands:

```
config system global
set gui-local-in-policy enable
end
```

The Local-In Policy page will then be available in **Policy & Objects > Local In Policy**. You can configure what local-in traffic to log in the CLI, or in **Log & Report > Log Settings**, under **Local Traffic Logging**.

When deciding what local-in policy traffic you want logged, consider the following:

## Special Traffic

| Traffic activity                                                                  | Traffic Direction | Description                                                                                                   |
|-----------------------------------------------------------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------|
| <b>FortiGuard update announcements</b>                                            | IN                | All push announcements of updates that are coming from the FortiGuard system. For example, IPS or AV updates. |
| <b>FortiGuard update requests</b>                                                 | OUT               | All updates that are checking for antivirus or IPS as well as other FortiGuard service updates.               |
| <b>Firewall authentication</b>                                                    | IN                | The authentication made using either the web-based manager or CLI.                                            |
| <b>Central management (a FortiGate unit being managed by a FortiManager unit)</b> | IN                | The access that a FortiManager has managing the FortiGate unit.                                               |
| <b>DNS</b>                                                                        | IN                | All DNS traffic.                                                                                              |
| <b>DHCP/DHCP Relay</b>                                                            | IN                | All DHCP and/or DHCP Relay traffic.                                                                           |
| <b>HA (heart beat sync policy)</b>                                                | IN/OUT            | For high-end platforms with a backplane heart beat port.                                                      |
| <b>HA (Session sync policy)</b>                                                   | IN/OUT            | This will get information from the CMDB and updated by session sync daemon.                                   |
| <b>CAPWAP</b>                                                                     | IN                | This activity is logged only when a HAVE_CAPWAP is defined.                                                   |
| <b>Radius</b>                                                                     | IN                | This is recorded only within FortiCarrier.                                                                    |
| <b>NETBIOS forward</b>                                                            | IN                | Any interface that NETBIOS forward is enabled on.                                                             |
| <b>RIP</b>                                                                        | IN                |                                                                                                               |
| <b>OSPF</b>                                                                       | IN                |                                                                                                               |
| <b>VRRP</b>                                                                       | IN                |                                                                                                               |
| <b>BFD</b>                                                                        | IN                |                                                                                                               |
| <b>IGMP</b>                                                                       | IN                | This is recorded only when PIM is enabled.                                                                    |
| <b>PIM</b>                                                                        | IN                | This is recorded only when PIM is enabled.                                                                    |

| Traffic activity                  | Traffic Direction | Description                                                                                                      |
|-----------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------|
| <b>BGP</b>                        | IN                | This is recorded only when config bgp and bgp neighbor is enabled in the CLI.                                    |
| <b>WCCP policy</b>                | IN                | Any interface that WCCP is enabled; however, if in Cache mode, this is not recorded because it is not available. |
| <b>WAN Opt/ Web Cache</b>         | IN                | Any interface where WAN Opt is enabled.                                                                          |
| <b>WANOpt Tunnel</b>              | IN                | This is recorded when HAVE_WANOPT is defined.                                                                    |
| <b>SSL-VPN</b>                    | IN                | Any interface from a zone where the action in the policy is SSL VPN.                                             |
| <b>IPSEC</b>                      | IN                |                                                                                                                  |
| <b>L2TP</b>                       | IN                |                                                                                                                  |
| <b>PPTP</b>                       | IN                |                                                                                                                  |
| <b>VPD</b>                        | IN                | This is recorded only when FortiClient is enabled.                                                               |
| <b>Web cache db test facility</b> | IN                | This is recorded only when WA_CS_REMOTE_TEST is defined.                                                         |
| <b>GDBserver</b>                  | IN                | This is recorded only when debug is enabled.                                                                     |

## Tracking specific search phrases in reports

It is possible to use the Web Filter to track specific search keywords and phrases and record the results for display in the report.

You should verify that the web filter profile you are using indicates what search phrases you want to track and monitor, so that the report includes this information.

### 1. Log in to the CLI and enter show webfilter profile default.

This provides details about the webfilter profile being used by the security policy. In this example, the details (shown in the following in bold) indicate that safe search is enabled, but not specified or being logged.

```
show webfilter profile default
config webfilter profile
edit "default"
 set comment "default web filtering"
 set inspection-mode flow-based
 set options https-scan
 set post-action comfort
 config web
 set safe-search url
 end
 config ftgd-wf
 config filters
 edit 1
```

```
 set action block
 set category 2
 next
 edit 2
 set action block
 set category 7
 next
 edit 3
 set action block
 set category 8
```

2. Enter the following command syntax so that logging and the keyword for the safe search will be included in logging.

```
config webfilter profile
 edit default
 config web
 set log-search enable
 set keyword-match "fortinet" "easter" "easter bunny"
 end
 end
```

3. To test that the keyword search is working, go to a web browser and begin searching for the words that were included in the webfilter profile, such as easter.

You can tell that the test works by going to **Log & Report > Forward Traffic** and viewing the log messages.

## Troubleshooting and logging

This section explains how to troubleshoot logging configuration issues, as well as connection issues, that you may have with your FortiGate unit and a log device. This section also contains information about how to use log messages when troubleshooting issues that are about other FortiGate features, such as VPN tunnel errors.

### Using log messages to help in troubleshooting issues

Log messages can help when troubleshooting issues that occur, since they can provide details about what is occurring. The uses and methods for involving logging in troubleshooting vary depending on the problem. The following are examples of how log messages can assist when troubleshooting networking issues.

#### Using IPS packet logging in diagnostics

This type of logging should only be enabled when you need to know about specific diagnostic information, for example, when you suspect a signature is triggered by a false positive. These log messages can help troubleshoot individual problems with misidentified or missing packets and network intrusions involving malicious packets.

##### To configure IPS packet logging

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the IPS sensor that you want to enable IPS packet logging on, and then select **Edit**.
3. In the filter options, enable **Packet Logging**.
4. Select **OK**.

If you want to configure the packet quota, number of packets that are recorded before alerts and after attacks, use the following procedure.

##### To configure additional settings for IPS packet logging

1. Log in to the CLI.
2. Enter the following to start configuring additional settings:

```
config ips settings
 set ips-packet-quota <integer>
 set packet-log-history <integer>
 set packet-log-post-attack <integer>
end
```

#### Using HA log messages to determine system status

When the FortiGate unit is in HA mode, you may see the following log message content within the event log:

```
type=event subtype=ha level=critical msg= "HA slave heartbeat interface internal lost
neighbor information"
```

OR

```
type=event subtype=ha level=critical msg= "Virtual cluster 1 of group 0 detected new
joined HA member"
```

OR

```
type=event subtype=ha level=critical msg= "HA master heartbeat interface internal get peer
information"
```

The log messages occur within a given time, and indicate that the units within the cluster are not aware of each other anymore. These log messages provide the information you need to fix the problem.

## Connection issues between FortiGate unit and logging devices

If external logging devices are not recording the log information properly or at all, the problem will likely be due to one of two situations: no data is being received because the log device cannot be reached, or no data is being sent because the FortiGate unit is no longer logging properly.

### Unable to connect to a supported log device

After configuring logging to a supported log device, and testing the connection, you may find you cannot connect. To determine whether this is the problem:

1. Verify that the information you entered is correct; it could be a simple mistake within the IP address or you may have not selected **Apply** on the Log Settings page after changing them, which would prevent them from taking effect.
2. Use `execute ping` to see if you can ping to the log device.
3. If you are unable to ping to the log device, check to see if the log device itself working and that it is on the network and assigned an appropriate address.

### FortiGate unit has stopped logging

If the FortiGate unit stopped logging to a device, test the connection between both the FortiGate unit and device using the `execute ping` command. The log device may have been turned off, is upgrading to a new firmware version, or just not working properly.

The FortiGate unit may also have a corrupted log database. When you log into the web-based manager and you see an SQL database error message, it is because the SQL database has become corrupted. View "SQL database errors" in the next section before taking any further actions, to avoid losing your current logs.

## Log database issues

If attempting to troubleshoot issues with the SQL log database, use the following to help guide you to solving issues that occur.

### SQL statement syntax errors

There may be errors or inconsistencies in the SQL used to maintain the database. Here are some example error messages and possible causes:

```
You have an error in your SQL syntax (remote/MySQL)
```

```
or
```

```
ERROR: syntax error at or near... (local/PostgreSQL)
```

- Verify that the SQL keywords are spelled correctly, and that the query is well-formed.
- Table and column names are demarked by grave accent (`) characters. Single (') and double (") quotation marks will cause an error.

```
No data is covered.
```

- The query is correctly formed, but no data has been logged for the log type. Verify that you have configured the FortiGate unit to save that log type. On the Log Settings page, make sure that the log type is checked.

## Connection problems

If well-formed SQL queries do not produce results, and logging is turned on for the log type, there may be a database configuration problem with the remote database.

Ensure that:

- MySQL is running and using the default port 3306.
- You have created an empty database and a user who has read/write permissions for the database.
- Here is an example of creating a new MySQL database named fazlogs, and adding a user for the database:

1. `#Mysql -u root -p`
2. `mysql> Create database fazlogs;`
3. `mysql> Grant all privileges on fazlogs.* to 'fazlogger'@'*' identified by 'fazpassword';`
4. `mysql> Grant all privileges on fazlogs.* to 'fazlogger'@'localhost' identified by 'fazpassword';`

## SQL database errors

If the database seems inaccessible, you may encounter the following error message after upgrading or downgrading the FortiGate unit's firmware image.

### Example of an SQL database error message

The error message indicates that the SQL database is corrupted and cannot be updated with the SQL schemas any more. When you see this error message, you can do one of the following:

- select **Cancel** and back up all log files; then select **Rebuild** to blank and rebuild the database.
- select **Rebuild** immediately, which will blank the database and previous logs will be lost.

Until the database is rebuilt, no information will be logged by the FortiGate unit regardless of the log settings that are configured on the unit. When you select **Rebuild**, all logs are lost because the SQL database is erased and then rebuilt again. Logging resumes automatically according to your settings after the SQL database is rebuilt.

To view the status of the database, use the `diagnose debug sqlldb-error status` command in the CLI. This command will inform you whether the database has errors present.

If you want to view the database's errors, use the `diagnose debug sqlldb-error read` command in the CLI. This command indicates exactly what errors occurred, and what tables contain those errors.

Log files are backed up using the `execute backup {disk | memory} {alllogs | logs}` command in the CLI. You must use the text variable when backing up log files because the text variable allows you to view the log files outside the FortiGate unit. When you back up log files, you are really just copying the log files from the database to a specified location, such as a TFTP server.

## Logging daemon (Miglogd)

The number of logging daemon child processes has been made available for editing. A higher number can affect performance, and a lower number can affect log processing time, although no logs will be dropped or lost if the number is decreased.

If you are suffering from performance issues, you can alter the number of logging daemon child processes, from 0 to 15, using the following syntax. The default is 8.

```
config system global
 set miglogd-children <integer>
end
```

There is currently no supported method for monitoring and triggering alert messages based on current logging status, logging activity, or miglogd status. Alert emails can be sent based on log disk capacity status.

---

# Chapter 19 - Managing Devices

## Managing devices

Welcome and thank you for selecting Fortinet products for your network protection.

This chapter contains the following topics:

### Before you begin

Before you begin using this guide, please ensure that:

- You have administrative access to the web-based manager and/or CLI.
- The FortiGate unit is integrated into your network.
- The operation mode has been configured.
- The system time, DNS settings, administrator password, and network interfaces have been configured.
- Firmware, FortiGuard Antivirus and FortiGuard Antispam updates are completed.
- Any third-party software or servers have been configured using their documentation.

While using the instructions in this guide, note that administrators are assumed to be super\_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

### How this guide is organized

This handbook chapter contains the following sections:

[Managing “bring your own device”](#) describes device monitoring, devices, device groups, and device policies. The administrator can monitor all types of devices and control their access to network resources.

## What's New in FortiOS 5.6

This chapter describes new Device identification features added to FortiOS 5.6.

### FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

#### Changed default for device-identification-active-scan to disabled (380837)

It was decided that most customers would not appreciate a default setting that resulted in the FortiGate probing their systems, so active scan option is changed to disabled by default going forward, but upgrade code is added to keep the option enabled for those upgrading from 5.4.0 or 5.4.1 who were using device-identification with active scan enabled.

## Managing “bring your own device”

FortiOS can control network access for different types of personal mobile devices that your employees bring onto your premises. You can:

- identify and monitor the types of devices connecting to your networks, wireless or wired
- use MAC address based access control to allow or deny individual devices
- create security policies that specify device types
- enforce endpoint control on devices that can run FortiClient Endpoint Control software

This chapter contains the following sections:

### Device monitoring

The FortiGate unit can monitor your networks and gather information about the devices operating on those networks. Collected information includes:

- MAC address
- IP address
- operating system
- hostname
- user name
- how long ago the device was detected and on which FortiGate interface

You can go to **User & Device > Device Inventory** to view this information. Mouse-over the **Device** column for more details.

Depending on the information available, the Device column lists the Alias or the MAC address of the device. For ease in identifying devices, Fortinet recommends that you assign each device an Alias.

Device monitoring is enabled separately on each interface. Device detection is intended for devices directly connected to your LAN ports. If enabled on a WAN port, device detection may be unable to determine the operating system on some devices. Hosts whose device type cannot be determined passively can be found by enabling active scanning on the interface.

You can also manually add devices. This enables you to ensure that a device with multiple interfaces is displayed as a single device.

### To configure device monitoring

1. Go to **Network > Interfaces**.
2. Edit the interface that you want to monitor devices on.
3. In **Networked Devices**, turn on **Device Detection** and optionally turn on **Active Scanning**.
4. Select **OK**.
5. Repeat steps 2 through 4 for each interface that will monitor devices.

### To assign an alias to a detected device or change device information

1. Go to **User & Device > Device Inventory** and edit the device entry.
2. Enter an **Alias** such as the user's name to identify the device.
3. Change other information as needed.
4. Select **OK**.

### To add a device manually

1. Go to **User & Device > Custom Devices & Groups**.
2. Select **Create New > Device**.
3. Enter the following information:
  - Alias (required)
  - MAC address
  - Additional MACs (other interfaces of this device)
  - Device Type
  - Optionally, add the device to **Custom Groups**.
  - Optionally, enter **Comments**.
3. Select **OK**.

### Custom avatars for custom devices

You can upload an avatar for a custom device. The avatar is then displayed in the GUI wherever the device is listed, such as FortiView, log viewer, or policy configuration. To upload an avatar image, click **Upload Image** on the New Device or Edit Device page of **User & Device > Custom Devices & Groups**. The image can be in any format your browser supports and will be automatically sized to 36 x 36 pixels for use in the FortiGate GUI.

### Device offline timeout

A device is considered offline if it has not sent any packets during the timeout period. The timeout can be set to any value from 30 to 31 536 000 seconds (365 days). The default value is 300 seconds (5 minutes). The timer is configurable in the CLI:

```
config system global
 set device-idle-timeout 300
end
```

## Device Groups

You can specify multiple device types in a security policy. As an alternative, you can add multiple device types to a custom device group and include the group in the policy. This enables you to create a different policy for devices

that you know than for devices in general.

### To create a custom device group and add devices to it

1. Go to **User & Device > Custom Devices & Groups**.  
The list of device groups is displayed.
2. Select **Create New > Device Group**.
3. Enter a **Name** for the new device group.
4. Click in the **Members** field and click a device type to add. Repeat to add other devices.
5. Select **OK**.

## Controlling access with a MAC Address Access Control List

A MAC Address Access Control List (ACL) allows or blocks access on a network interface that includes a DHCP server. If the interface does not use DHCP, or if you want to limit network access to a larger group such as employee devices, it is better to create a device group and specify that group in your security policies.

A MAC Address ACL functions as either

- a list of devices to block, allowing all other devices

or

- a list of devices to allow, blocking all other devices

Allowed devices are assigned an IP address. The Assign IP action assigns the device an IP address from the DHCP range. In a list of allowed devices, you can also use the Reserve IP action to always provide a specific IP address to the device.

The **Unknown MAC Address** entry applies to "other" unknown, unlisted devices. Its action must be opposite to that of the other entries. In an allow list, it must block. In a block list, it must allow.

### To create a MAC Address ACL to allow only specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.  
**DHCP Server** must be enabled.
3. In **MAC Reservation + Access Control**, select **Create New** and enter an allowed device's **MAC Address**.
4. In the **IP or Action** column, select one of:
  - Assign IP — device is assigned an IP address from the DHCP server address range.
  - Reserve IP — device is assigned the IP address that you specify.
5. Repeat Steps "[Controlling access with a MAC Address Access Control List](#)" on page 2338 and "[Controlling access with a MAC Address Access Control List](#)" on page 2338 for each additional MAC address entry.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Block**.  
Devices not in the list will be blocked.
7. Select **OK**.

### To create a MAC Address ACL to block specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.  
**DHCP Server** must be enabled.

3. In **MAC Reservation + Access Control**, select **Create New** and enter the **MAC Address** of a device that must be blocked.
4. In the **IP or Action** column, select **Block**.
5. Repeat Steps ["Controlling access with a MAC Address Access Control List" on page 2338](#) and ["Controlling access with a MAC Address Access Control List" on page 2338](#) for each device that must be blocked.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Assign IP**.  
Devices not in the list will be assigned IP addresses.
7. Select **OK**.

## MAC Authentication Bypass (MAB)

MAC Authentication Bypass allows devices without 802.1X capability (printers and IP phones for example) to bypass authentication and be allowed network access based on their MAC address. This feature requires RADIUS-based 802.1X authentication in which the RADIUS server contains a database of authorized MAC addresses.

MAC Authentication Bypass is configurable only in the CLI and only on interfaces configured for 802.1X authentication. For example:

```
config system interface
 edit "lan"
 set ip 10.0.0.200 255.255.255.0
 set vlanforward enable
 set security-mode 802.1X
 set security-mac-auth-bypass enable
 set security-groups "Radius-group"
 end
end
```

MAC Authentication Bypass is also available on WiFi SSIDs, regardless of authentication type. It is configurable only in the CLI. You need to enable the `radius-mac-auth` feature and specify the RADIUS server that will be used. For example:

```
config wireless-controller vap
 edit "office-ssid"
 set security wpa2-only-enterprise
 set auth usergroup
 set usergroup "staff"
 set radius-mac-auth enable
 set radius-mac-auth-server "ourRadius"
 end
end
```

## Security policies for devices

Security policies enable you to implement policies according to device type. For example:

- Gaming consoles cannot connect to the company network or the Internet.
- Personal tablet and phone devices can connect to the Internet but not to company servers.
- Company-issued laptop computers can connect to the Internet and company servers. Web filtering and antivirus are applied.
- Employee laptop computers can connect to the Internet, but web filtering is applied. They can also connect to company networks, but only if FortiClient Endpoint Security is installed to protect against viruses.

The following images show these policies implemented for WiFi to the company network and to the Internet.

**Device policies for company laptop access to the company network**

| New Policy          |                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name                | Laptop LAN Access                                                                                                                                                                                                                                                                                                                                                            |
| Incoming Interface  |  internal (lan)                                                                                                                                                                                          |

The next section explains device policy creation in detail.

### Creating device policies

Device-based security policies are similar to policies based on user identity:

- The policy enables traffic to flow from one network interface to another.
- NAT can be enabled.
- UTM protection can be applied.

#### To create a device policy

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Choose **Incoming Interface**, **Outgoing Interface** and **Source** as you would for any security policy.
3. In **Source**, select an address and the device types that can use this policy.  
You can select multiple devices or device groups.
4. Turn on **NAT** if appropriate.
5. Configure **Security Profiles** as you would for any security policy.
6. Select **OK**.

## Adding endpoint protection

Optionally, you can require that users' devices connecting to a particular network interface have FortiClient Endpoint Security software installed. Devices without an up-to-date installation of FortiClient software are restricted to a captive portal from which the user can download a FortiClient installer. For information about creating FortiClient profiles, see "Endpoint Protection".

### To add endpoint protection to a security policy

1. Go to **Network > Interfaces** and edit the interface.
2. In **Admission Control** turn on **Allow FortiClient Connections** and **FortiClient Enforcement**.
3. Optionally, select sources (addresses and device types) to exempt from FortiClient enforcement.
4. Optionally, select destination addresses and services to exempt from FortiClient enforcement.
5. Select **OK**.

FortiOS pushes a FortiClient profile out to the FortiClient software, configuring network protection such as antivirus, application control, and web category filtering. To create these profiles, go to **Security Profiles > FortiClient Profiles**.

### FortiClient Endpoint licence updates

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum ([forum.fortinet.com](http://forum.fortinet.com)). Phone support is only available for paid licenses.

| Model(s)                            | Maximum client limit |
|-------------------------------------|----------------------|
| VM00                                | 200                  |
| FGT/FWF 30 to 90 series             | 200                  |
| FGT 100 to 400 series               | 600                  |
| FGT 500 to 900 series, VM01, VM02   | 2,000                |
| FGT 1000 to 2900 series             | 20,000               |
| FGT 3000 to 3600 series, VM04       | 50,000               |
| FGT 3700D and above, VM08 and above | 100,000              |

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

# Chapter 20 - Managing a FortiSwitch with a FortiGate

## Managing a FortiSwitch with a FortiGate

**NOTE:** FortiLink is not supported in Transparent mode.

The maximum number of supported FortiSwitches depends on the FortiGate model:

| FortiGate Model Range                            | Number of FortiSwitches Supported |
|--------------------------------------------------|-----------------------------------|
| Up to FortiGate-98 and FortiGate-VM01            | 8                                 |
| FortiGate-100 to 280 and FortiGate-VM02          | 24                                |
| FortiGate-300 to 5xx                             | 48                                |
| FortiGate-600 to 900 and FortiGate-VM04          | 64                                |
| FortiGate-1000 and up                            | 128                               |
| FortiGate-3xxx and up, and FortiGate-VM08 and up | 256                               |

## Supported models

The following table shows the FortiSwitch models that support FortiLink mode when paired with the corresponding FortiGate models and the listed minimum software releases.

| FortiGate and FortiWiFi Models                                                                                                                             | Earliest FortiOS | FortiSwitch Models                                                                   |
|------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------|

Refer to [Managing a FortiSwitch with a FortiGate on page 2343](#) for details about the features supported on each FortiSwitch model.

## Before you begin

Before you start administrating your FortiSwitch unit, it is assumed that you have completed the initial configuration of the FortiSwitch unit, as outlined in the QuickStart Guide for your FortiSwitch model and have

administrative access to the FortiSwitch unit's Web-based manager and CLI.

## What's new for managed FortiSwitches in FortiOS 5.6.3 with FortiSwitch 3.6.3 (and later releases)

This section describes new managed FortiSwitch features in FortiOS 5.6.3 with FortiSwitch 3.6.3.

### Firewall policy now required for RADIUS traffic (434470)

In FortiLink mode, you must manually create a firewall policy to allow RADIUS traffic for 802.1x authentication from the FortiSwitch (for example, from the FortiLink interface) to the RADIUS server through the FortiGate.

### STP root guard (376015)

Enable root guard on all ports that should not be root bridges. Do not enable root guard on the root port. You must have STP enabled to be able to use root guard.

#### Using the FortiGate GUI

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Right-click on a port.
3. Select **Enable** or **Disable**.

#### Using the FortiGate CLI

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port name>
 set stp-root-guard {enabled | disabled}
 end
 end
 end
```

### STP BPDU guard (406182)

When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

There are two prerequisites for using BPDU guard:

- You must define the port as an edge port with the `set edge-port enable` command.
- You must enable STP on the switch interface with the `set stp-state enabled` command.

#### Using the FortiGate GUI

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Right-click on a port.
3. Select **Enable** or **Disable**.

#### Using the FortiGate CLI

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
```

```

edit <port name>
 set stp-bpdu-guard {enabled | disabled}
 set stp-bpdu-guard-time <0-120>
end
end

```

### FortiSwitch log message changes (438738)

More details are now provided in exported FortiSwitch logs, for example:

- New Switch-Controller user field and daemon-name ui fields.
- Removed Switch-Controller keyword from the msg field
- Changed UpdSwConf keyword in msg field to FortiSwitch in flcfgd logs
- Removed the VDOM keyword from the msg field in flcfgd logs
- Removed the Fortiswitch keyword before SN in the msg field
- Changed syslog to have switch SN first followed by a space and then the first word following with a capital (in the msg field)

Use the following CLI commands to enable the export of FortiSwitch logs and to set the level of logging included. The system logs all messages at and above the logging severity level you select. For example, if you select **error**, the system logs error, critical, alert, and emergency level messages.

```

config switch-controller switch-log
 set status (*enable | disable)
 set severity [emergency | alert | critical | error | warning | notification |
 *information | debug]
end

```

### Support FSW BPDU Guard (442921) (442922)

With standard STP, a device that sends BPDU(s) to any switch port becomes a member of that switch's STP network topology. In order to enforce a network edge, the access ports on the switch can be configured with BPDU guard. With BPDU guard enabled, the port does not forward BPDUs upstream (toward its root bridge). Instead, when a BPDU guard enabled port receives any BPDU, it immediately puts the port into a blocking state and alerts the user.

This prevents the access port from accepting the downstream device, removing it from the receiving switch's STP calculations. In order to unblock the port after bpdu guard has triggered, the user must execute a reset command. After the port is reset, it will resume normal operation and return to a blocking state only if another BPDU is received.

BPDU guard is typically used in conjunction with Root Guard to enforce a specific network topology.

### Syntax

```

config switch-controller managed-switch
 edit <switch SN>
 config ports
 edit <port>
 set stp-bpdu-guard <enable | *disable>
 set stp-bpdu-guard-timeout <time> (0-120 in minutes)
 next
 end
 next
end

```

```

config switch-controller managed-switch
 edit <switch SN>
 config ports
 edit <port>
 set stp-root-guard <enable | *disable>
 next
 end
 next
end

diagnose switch-controller dump stp <switch SN> <instance>
diagnose switch-controller bpdu-guard-status <switch SN>

```

### Managed switch CLI features added to GUI (448722)

Added new optional columns "Edge Port", "LLDP Profile", "QoS Policy", "STP BPDU Guard", "STP Root Guard" in **WiFi & Switch Controller > FortiSwitch Ports**.

This would allow administrators to make changes to the features above to multiple switch ports at the same time.

### Added unit in help-text when setting max-rate/min-rate under switch-controller qos queue-policy (449487) (449869)

Modified the CLI help-text on the FortiGate to show priority under strict schedule when setting max-rate/min-rate under switch-controller qos queue-policy.

#### Syntax

```

set priority-0
 queue-0 COS queue 0. (lowest priority)
 queue-1 COS queue 1.
 queue-2 COS queue 2.
 queue-3 COS queue 3.
 queue-4 COS queue 4.
 queue-5 COS queue 5.
 queue-6 COS queue 6.
 queue-7 COS queue 7. (highest priority)

```

### Added FortiSwitch factory-reset functionality to the FortiOS GUI (393205)

Added a **Factory Reset** button to the **WiFi & Switch Controller > Managed FortiSwitch** page when a FortiSwitch document is selected.

#### Syntax

```
execute switch-controller factory-rest <switch sn>
```

## What's new for managed FortiSwitches in FortiOS 5.6.1 with FortiSwitch 3.6.0 (and later releases)

This section describes new managed FortiSwitch features in FortiOS 5.6.1 with FortiSwitch 3.6.0.

## Simplified method to convert a FortiSwitch to standalone mode (393205)

There is an easier way to convert a FortiSwitch from FortiLink mode to standalone mode so that it will no longer be managed by a FortiGate:

- `execute switch-controller factory-reset <switch-id>`  
This command returns the FortiSwitch to the factory defaults and then reboots the FortiSwitch. If the FortiSwitch is configured for FortiLink auto-discovery, FortiGate can detect and automatically authorize the FortiSwitch.
- `execute switch-controller set-standalone <switch-id>`  
This command returns the FortiSwitch to the factory defaults, reboots the FortiSwitch, and prevents the FortiGate from automatically detecting and authorizing the FortiSwitch.

You can disable FortiLink auto-discovery on multiple FortiSwitches using the following commands:

```
config switch-controller global
 set disable-discovery <switch-id>
end
```

You can also add or remove entries from the list of FortiSwitches that have FortiLink auto-discovery disabled using the following commands:

```
config switch-controller global
 append disable-discovery <switch-id>
 unselect disable-discovery <switch-id>
end
```

## Quarantines (410828)

Quarantined MAC addresses are blocked on the connected FortiSwitches from the network and the LAN.

**NOTE:** You must enable the quarantine feature in the FortiGate CLI using the `set quarantine enable` command. You can add MAC addresses to the quarantine list before enabling the quarantine feature, but the quarantine does not go into effect until enabled.

### Quarantining a MAC address

#### Using the FortiGate GUI

1. Select the host to quarantine.
  - Go to **Security Fabric > Physical Topology**, right-click on a host, and select **Quarantine Host on FortiSwitch**.
  - Go to **Security Fabric > Logical Topology**, right-click on a host, and select **Quarantine Host on FortiSwitch**.
  - Go to **FortiView > Sources**, right-click on an entry in the Source column, and select **Quarantine Host on FortiSwitch**.
2. Click **OK** to confirm that you want to quarantine the host.

#### Using the FortiGate CLI

```
config switch-controller quarantine
 set quarantine enable
 edit <MAC_address>
 set description <string>
 set tags <tag1 tag2 tag3 ...>
 next
```

```

 next
end

```

| Option             | Description                                                      |
|--------------------|------------------------------------------------------------------|
| MAC_address        | A layer-2 MAC address in the following format: 12:34:56:aa:bb:cc |
| string             | Optional. A description of the MAC address being quarantined.    |
| tag1 tag2 tag3 ... | Optional. A list of arbitrary strings.                           |

### Viewing quarantine entries

Quarantine entries are created on the FortiGate that is managing the FortiSwitch.

#### Using the FortiGate GUI

1. Go to **Monitor > Quarantine Monitor**.
2. Click **Quarantined on FortiSwitch**.

#### Using the FortiGate CLI

Use the following command to view the quarantine list of MAC addresses:

```
show switch-controller quarantine
```

When the quarantine feature is enabled on the FortiGate, it creates a quarantine VLAN (qtn.<FortiLink\_port\_name>) on the virtual domain. The quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports.

Use the following command to view the quarantine VLAN:

```
show system interface qtn.<FortiLink_port_name>
```

Use the following command to view how the quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports:

```
show switch-controller managed-switch
```

### Releasing MAC addresses from quarantine

#### Using the FortiGate GUI

1. Go to **Monitor > Quarantine Monitor**.
2. Click **Quarantined on FortiSwitch**.
3. Right-click on one of the entries and select **Delete** or **Remove All**.
4. Click **OK** to confirm your choice.

#### Using the FortiGate CLI

Use the following commands to delete a quarantined MAC address:

```
config switch-controller quarantine
config targets
```

```
delete <MAC_address>
end
```

When the quarantine feature is disabled, all quarantined MAC addresses are released from quarantine. Use the following commands to disable the quarantine feature:

```
config switch-controller quarantine
set quarantine disable
end
```

### Assign untagged VLANs to a managed FortiSwitch port (410828)

Use the following commands to assign untagged VLANs to a managed FortiSwitch port:

```
config switch-controller managed-switch
edit <managed-switch>
config ports
edit <port>
set untagged-vlans <VLAN-name>
next
end
next
end
```

### View, create, and assign multiple 802.1X policy definitions (408389 and 403901)

Previously, you could create one 802.1X policy for all managed FortiSwitches in a virtual domain. Now, you can create multiple 802.1X policies and assign a different 802.1X policy to each managed FortiSwitch port.

#### View security policies for managed FortiSwitches

You can view security policies for managed FortiSwitches in two places:

- Go to **WiFi & Switch Controller > FortiSwitch Security Policies**.
- Go to **WiFi & Switch Controller > FortiSwitch Ports** and click the **+** next to a FortiSwitch. The security policy for each port is listed in the Security Policy column.

#### Create and assign multiple 802.1X policy definitions for managed FortiSwitches

Previously, you could create one 802.1X policy for all managed FortiSwitches in a virtual domain. Now, you can create multiple 802.1X policies and assign a different 802.1X policy to each managed FortiSwitch port.

**To create an 802.1X security policy:**

1. Go to **WiFi & Switch Controller > FortiSwitch Security Policies**.
2. Click **Create New**.
3. Enter a name for the new FortiSwitch security policy.
4. For the security mode, select **Port-based** or **MAC-based**.
5. Click **+** to select which user groups will have access.
6. Enable or disable guest VLANs on this interface to allow restricted access for some users.
7. Enter the number of seconds for authentication delay for guest VLANs. The range is 60-900 seconds.
8. Enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN.
9. Enable or disable MAC authentication bypass (MAB) on this interface.

10. Enable or disable EAP pass-through mode on this interface.
11. Enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.
12. Click **OK**.

**To apply an 802.1X security policy to a managed FortiSwitch port:**

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**.
2. Click the **+** next to a FortiSwitch.
3. In the Security Policy column for a port, click **+** to select a security policy.
4. Click **OK** to apply the security policy to that port.

### Override 802.1X settings

**To override the 802.1X settings for a virtual domain:**

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click on a FortiSwitch faceplate and click **Edit**.
3. In the Edit Managed FortiSwitch page, move the **Override 802-1X settings** slider to the right.
4. In the Reauthentication Interval field, enter the number of minutes before reauthentication is required. The maximum interval is 1,440 minutes. Setting the value to 0 minutes disables reauthentication.
5. In the Max Reauthentication Attempts field, enter the maximum times that reauthentication is attempted. The maximum number of attempts is 15. Setting the value to 0 disables reauthentication.
6. Select **Deauthenticate** or **None** for the link down action. Selecting **Deauthenticate** sets the interface to unauthenticated when a link is down, and reauthentication is needed. Selecting **None** means that the interface does not need to be reauthenticated when a link is down.
7. Click **OK**.

### Enable and disable switch-controller access VLANs through FortiGate (406718)

Access VLANs are VLANs that aggregate client traffic solely to the FortiGate. This prevents direct client-to-client traffic visibility at the layer-2 VLAN layer. Clients can only communicate with the FortiGate. After the client traffic reaches the FortiGate, the FortiGate can then determine whether to allow various levels of access to the client by shifting the client's network VLAN as appropriate.

Use `enable` to allow traffic only to and from the FortiGate and to block FortiSwitch port-to-port traffic on the specified VLAN. Use `disable` to allow normal traffic on the specified VLAN.

```
config system interface
 edit <VLAN name>
 set switch-controller-access-vlan {enable | disable}
 next
end
```

### Override the admin password for all managed FortiSwitches (416261)

By default, each FortiSwitch has an admin account without a password. To replace the admin passwords for all FortiSwitches managed by a FortiGate, use the following commands:

```
config switch-controller switch-profile
 edit default
 set login-passwd-override {enable | disable}
 set login-passwd <password>
 next
end
```

If you had already applied a profile with the override enabled and the password set and then decide to remove the admin password, you need to apply a profile with the override enabled and use the `unset login-passwd` command; otherwise, your previously set password will remain in the FortiSwitch.

## Configure an MCLAG with managed FortiSwitches (366617)

To configure a multichassis LAG (MCLAG) with managed FortiSwitches:

1. For each MCLAG peer switch, log into the FortiSwitch to create a LAG:

```
config switch trunk
 edit "LAG-member"
 set mode lacp-active
 set mclag-icl enable
 set members "<port>" "<port>"
 next
```

2. Enable the MCLAG on each managed FortiSwitch:

```
config switch-controller managed-switch
 edit "<switch-id>"
 config ports
 edit "<trunk name>"
 set type trunk
 set mode {static | lacp-passive | lacp-active}
 set bundle {enable | disable}
 set members "<port>,<port>"
 set mclag {enable | disable}
 next
 end
 next
```

3. Log into each managed FortiSwitch to check the MCLAG configuration:

```
diagnose switch mclag
```

After the FortiSwitches are configured as MCLAG peer switches, any port that supports advanced features on the FortiSwitch can become a LAG port. When `mclag` is enabled and the LAG port names match, an MCLAG peer set is automatically formed. The member ports for each FortiSwitch in the MCLAG do not need to be identical to the member ports on the peer FortiSwitch.

## Configure QoS with managed FortiSwitches (373581)

Quality of Service (QoS) provides the ability to set particular priorities for different applications, users, or data flows. **NOTE:** FortiGate does not support QoS for hard or soft switch ports.

To configure the QoS for managed FortiSwitches:

1. Configure a Dot1p map.

```
config switch-controller qos dot1p-map
 edit <Dot1p map name>
 set description <text>
 set priority-0 <queue number>
```

```

 set priority-1 <queue number>
 set priority-2 <queue number>
 set priority-3 <queue number>
 set priority-4 <queue number>
 set priority-5 <queue number>
 set priority-6 <queue number>
 set priority-7 <queue number>
 next
end

```

## 2. Configure a DSCP map.

```

config switch-controller qos ip-dscp-map
 edit <DSCP map name>
 set description <text>
 configure map <map_name>
 edit <entry name>
 set cos-queue <COS queue number>
 set diffserv {CS0 | CS1 | AF11 | AF12 | AF13 | CS2 | AF21 | AF22 | AF23
 | CS3 | AF31 | AF32 | AF33 | CS4 | AF41 | AF42 | AF43 | CS5 | EF |
 CS6 | CS7}
 set ip-precedence {network-control | internetwork-control | critic-ecp
 | flashoverride | flash | immediate | priority | routine}
 set value <DSCP raw value>
 next
 end
 end
end

```

## 3. Configure the egress QoS policy.

```

config switch-controller qos queue-policy
 edit <QoS egress policy name>
 set schedule {strict | round-robin | weighted}
 config cos-queue
 edit [queue-<number>]
 set description <text>
 set min-rate <rate in kbps>
 set max-rate <rate in kbps>
 set drop-policy {taildrop | random-early-detection}
 set weight <weight value>
 next
 end
 next
end

```

## 4. Configure the overall policy that will be applied to the switch ports.

```

config switch-controller qos qos-policy
 edit <QoS egress policy name>
 set default-cos <default CoS value 0-7>
 set trust-dot1p-map <Dot1p map name>
 set trust-ip-dscp-map <DSCP map name>
 set queue-policy <queue policy name>
 next
end

```

### 5. Configure each switch port.

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port>
 set qos-policy <CoS policy>
 next
 end
 next
end
```

### Reset PoE-enabled ports from the GUI (387417)

If you need to reset PoE-enabled ports, go to **WiFi & Switch Control > FortiSwitch Ports**, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

You can also go to **WiFi & Switch Control > Managed FortiSwitch** and click on a port icon for the FortiSwitch of interest. In the FortiSwitch Ports page, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

### Adding preauthorized FortiSwitches (382774)

After you preauthorize a FortiSwitch, you can assign the FortiSwitch ports to a VLAN.

#### To preauthorize a FortiSwitch:

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click **Create New**.
3. In the New Managed FortiSwitch page, enter the serial number, model name, and description of the FortiSwitch.
4. Move the **Authorized** slider to the right.
5. Click **OK**.

The Managed FortiSwitch page shows a FortiSwitch faceplate for the preauthorized switch.

## What's new for managed FortiSwitches in FortiOS 5.6 with FortiSwitch 3.6.0 (and later releases)

### IGMP snooping (387515)

The GUI and CLI support the ability to configure IGMP snooping for managed switch ports.

To enable IGMP snooping from the GUI, go to **WiFi & Switch Controller > FortiSwitch VLANs**, edit a VLAN and turn on **IGMP Snooping** under **Networked Devices**.

From the CLI, start by enabling IGMP snooping on the FortiGate:

```
config switch-controller igmp-snooping
 set aging-time <int>
 set flood-unknown-multicast (enable | disable)
end
```

Then enable IGMP snooping on a VLAN:

```
config system interface
 edit <vlan>
 set switch-controller-igmp-snooping (enable | disable)
```

```
end
```

Use the following command to enable IGMP snooping on switch ports, and to override the global parameters for a specific switch.

```
config switch-controller managed-switch
 edit <switch>
 config ports
 edit port <number>
 set igmp-snooping (enable | disable)
 set igmps-flood-reports (enable | disable)
 next
 config igmp-snooping globals
 set aging-time <int>
 set flood-unknown-multicast (enable | disable)
 end
 next
end
```

### User-port link aggregation groups (378470)

The GUI now supports the ability to configure user port LAGs on managed FortiSwitches.

**To create a link aggregation group for FortiSwitch user ports:**

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**
2. Click **Create New > Trunk**.
3. In the New Trunk Group page:
  - a. Enter a name for the trunk group
  - b. Select two or more physical ports to add to the trunk group
  - c. Select the mode: Static, Passive LACP, or Active LACP
4. Click **OK**.

### DHCP blocking, STP, and loop guard on managed FortiSwitch ports (375860)

The managed FortiSwitch GUI now supports the ability to enable/disable DHCP blocking, STP and loop guard for FortiSwitch user ports.

Go to **WiFi & Switch Controller > FortiSwitch Ports**. For any port you can select DHCP Blocking, STP, or Loop Guard. STP is enabled on all ports by default. Loop guard is disabled by default on all ports.

### Switch profile enhancements (387398)

Default switch profiles are bound to every switch discovered by the FortiGate. This means that an administrator can establish a password for this profile or create a new profile and bind that profile to any switch. Consequently, the password provided shall be configured on the FortiSwitch against the default "admin" account already present.

### Number of switches per FortiGate based on model (388024)

The maximum number of supported FortiSwitches depends on the FortiGate model:

| FortiGate Model Range                            | Number of FortiSwitches Supported |
|--------------------------------------------------|-----------------------------------|
| Up to FortiGate-98 and FortiGate-VM01            | 8                                 |
| FortiGate-100 to 280 and FortiGate-VM02          | 24                                |
| FortiGate-300 to 5xx                             | 48                                |
| FortiGate-600 to 900 and FortiGate-VM04          | 64                                |
| FortiGate-1000 and up                            | 128                               |
| FortiGate-3xxx and up, and FortiGate-VM08 and up | 256                               |

### Miscellaneous configuration option changes

- The default value of `dhcp-snooping` (also called DHCP-blocking) is changed from `trusted` in FortiOS 5.4 to `untrusted` in FortiOS 5.6.
- The default value of `edge-port` is changed from `disabled` in FortiOS 5.4 to `enabled` in FortiOS 5.6.0.
- The default value for DHCP snooping on the FortiLink VLAN (system interface) is changed from “enabled” in FortiOS 5.6.2 and earlier to “disabled” in FortiOS 5.6.3 and later. Note that, in the GUI, DHCP snooping is automatically changed to “enable” when the DHCP server is enabled on the interface.

### Additional GUI support

- Link aggregation of FortiSwitch ports
- DHCP trusted/untrusted, loop guard, and STP for FortiSwitch ports
- Connect to CLI support for FortiSwitch

## What's new for managed FortiSwitches in FortiOS 5.6 with FortiSwitch 3.5.4 (and later releases)

This section describes new managed FortiSwitch features in FortiOS 5.6 with FortiSwitch 3.5.4.

### Aggregating FortiSwitches into groups (397950)

In larger networks, the number of switches can be large. Different models and device purposes might exist. Furthermore, the topology might have “built-in” redundancy. Use the following command to create a FortiSwitch group allowing you to perform an operation on the entire group instead of one switch at a time.

```
config switch-controller switch-group
 edit <name>
 set description <string>
 set members <..> <..>
 end
end
```

### Pre-authentication and replacements of FortiSwitches (298533)

FortiSwitch configuration templates allow you to replace a FortiSwitch and have the configuration of the original FortiSwitch installed on the replacement.

Use the `execute replace-device fortiswitch <sn-old> <sn-new>` to transfer the configuration for the FortiSwitch with serial number `<sn-old>` to the replacement FortiSwitch with serial number `<sn-new>`.

### LLDP MED on managed FortiSwitches (372288)

FortiOS 5.6 supports configuring link layer discovery protocol-media endpoint discovery (LLDP MED) for managed FortiSwitches. Additionally, you can use FortiGate CLI commands display the information collected by LLDP on the FortiSwitch.

You can use the following command to add media endpoint discovery (MED) features to an LLDP profile.

```
config switch-controller lldp-profile
 edit <lldp-profile>
 config med-network-policy
 edit guest-voice
 set status {disable | enable}
 next
 edit guest-voice-signaling
 set status {disable | enable}
 next
 edit guest-voice-signaling
 set status {disable | enable}
 next
 edit softphone-voice
 set status {disable | enable}
 next
 edit streaming-video
 set status {disable | enable}
 next
 edit video-conferencing
 set status {disable | enable}
 next
 edit video-signaling
 set status {disable | enable}
 next
 edit voice
 set status {disable | enable}
 next
 edit voice-signaling
 set status {disable | enable}
 end
 config custom-tlvs
 edit <name>
 set oui <identifier>
 set subtype <subtype>
 set information-string <string>
 end
 end
end
```

### Enhanced 802.1x including FortiSwitch port security policy framework (389102)

New FortiSwitch port security features include:

- Dynamic VLAN Assignment
- “guest” and “auth-fail” VLAN

- Mac Address Bypass (MAB)
- Multiple host support on single physical port

### Global settings applied across the network

```
config switch-controller 802.1x-settings
 set reauth-period < int >
 set max-reauth-attempt < int >
 set link-down-auth < *set-unauth | no-action >
end
```

### Local switch overrides

```
config switch-controller managed-switch
 edit < switch >
 config 802.1x-settings
 set local-override {disable | enable}
 set reauth-period <int>
 set max-reauth-attempt <int>
 set link-down-auth {set-unauth | no-action}
 end
 next
end
```

### Policy definitions (802.1x and captive-portal)

```
config switch-controller security-policy 802.1x
 edit 8021X-policy-default
 set user-group <user.group>
 set mac-auth-bypas {disable | enable}
 set guest-vlan {disable | enable}
 set guest-vlanid <vlan-id>
 set guest-auth-delay <int>
 set auth-fail-vlan {disable | enable}
 set auth-fail-vlanid <vlan-id>
 radius-timeout-overwrite {disable | enable}
 end
end

config switch-controller security-policy captive-portal
 edit captive-portal-default
 set vlan <vlan-id>
 config users
 edit 1
 set user-group <usergroup>
 set vlanid <vlan-id>
 next
 end
 end
end
```

### Port settings

```
config switch-controller managed-switch
 edit <managed-switch>
```

```

config ports
 edit <port>
 set port-security-policy {802.1x-policy | captive-portal-policy}
 next
end
next
end

```

### Firmware upgrade management and compatible version information (385171)

You can view the current firmware version of a FortiSwitch and upgrade the FortiSwitch to a new firmware version by going to **WiFi & Switch Controller > Managed FortiSwitch** and editing one of the FortiSwitches. Under **Firmware** you can see the current firmware version and select **Update** to update it.

### Changed managed-switch display format for 'dynamic-capability' (387239)

FortiOS 5.6.0 displays capability flags as strings such as: dynamic-capability, igmp-snooping, dhcp-snooping, and so on. For example:

```

config switch-controller managed-switch
edit S124DP3X15000315
get
switch-id : S124DP3X15000315
name :
description :
fsw-wan1-peer : port9
fsw-wan1-admin : enable
fsw-wan2-peer :
fsw-wan2-admin : discovered
directly-connected : 0
connected : 1
version : 1
pre-provisioned : 0
dynamic-capability : igmp-snooping,dhcp-snooping
switch-device-tag :
dynamically-discovered: 1

```

### Connecting to a managed switch CLI from the FortiGate GUI (378119)

To connect to a FortiSwitch CLI, go to **WiFi & Switch Controller > Managed FortiSwitch**, right click on the FortiSwitch to connect to and select **Connect to CLI**. You can also open the FortiGate CLI console and use the `execute telnet <ip>` command, where <ip> is the management IP address of the FortiSwitch.

### Firmware upgrade of stacked or tiered switches (355050)

From your FortiGate CLI, you can upgrade the firmware of all of the managed FortiSwitches of the same model using a single `execute` command. The command includes the name of a firmware image file and all of the managed FortiSwitches compatible with that firmware image file are upgraded. For example:

```
execute switch-controller stage-tiered-swtp-image ALL <firmware-image-file>
```

You can also use the following new command to restart all of the managed FortiSwitches after a 2-minute delay.

```
execute switch-controller restart-swtp-delayed ALL
```

### More information displayed by the execute switch-controller get-conn-status command (388751)

The `get-conn-status` command now displays more information for each managed switch including the ID of each switch, the version of the firmware running on the switch, the status of the switch, the IP address for managing the switch, and its join time.

```
execute switch-controller get-conn-status
Managed-devices in current vdom root:
```

```
STACK-NAME: FortiSwitch-Stack-port3
SWITCH-ID VERSION STATUS ADDRESS JOIN-TIME NAME
FS108D3W16001177 v3.4 Authorized/Down 169.254.1.2 N/A My-Switch
```

### User-port link aggregation groups available on the GUI (378470)

The GUI now supports the ability to configure user port LAGs on managed FortiSwitches.

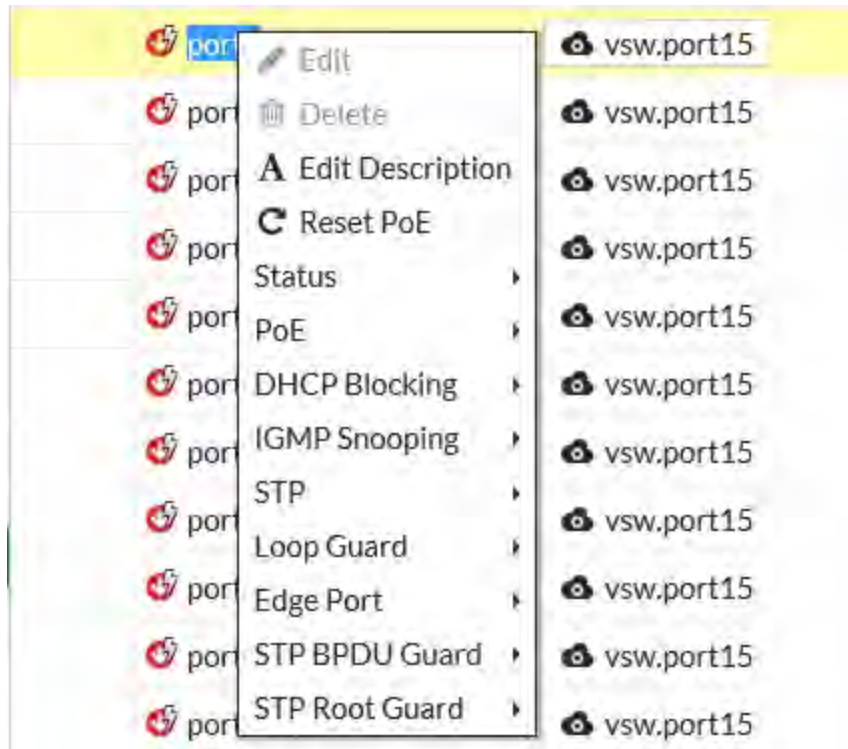

**To create a link aggregation group for FortiSwitch user ports:**

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**.
2. Click **Create New > Trunk**.
3. In the New Trunk Group page enter a **Name** for the trunk group.
4. Select two or more physical ports to add to the trunk group.
5. Select the **Mode**: Static, Passive LACP, or Active LACP.
6. Click OK.

### DHCP blocking, STP, and loop guard on managed FortiSwitch ports on the GUI (375860)

The managed FortiSwitch GUI now supports the ability to enable/disable DHCP blocking, STP and loop guard for FortiSwitch user ports.

Go to **WiFi & Switch Controller > FortiSwitch Ports**. For any port you can select DHCP Blocking, STP, or Loop Guard. STP is enabled on all ports by default. Loop guard is disabled by default on all ports.

### New switch profiles (387398)

Switch profiles allow specific settings to be applied to all authorized FortiSwitches. The default switch profile is automatically bound to every switch discovered by the FortiGate. You can create additional profiles as needed.

Within a switch profile, you can control the behavior of the FortiSwitch's admin account. You can add a password to a profile or create a new profile and bind that profile to any switch. The password provided in the profile is configured on the FortiSwitch to the default admin administrator account.

### Miscellaneous configuration option changes

- On a switch port, the default value of `dhcp-snooping` (also called DHCP-blocking) is changed from `trusted` in FortiOS 5.4 to `untrusted` in FortiOS 5.6.
- On a switch port, the default value of STP `edge-port` is changed from `disabled` in FortiOS 5.4 to `enabled` in FortiOS 5.6.0.
- The default value of `fortilink-split-port` is changed from `disable` in FortiOS 5.4.1/5.4.2 to `enable` in FortiOS 5.4.3 onward. This command applies to FortiGate aggregate interfaces.

```
config system interface
 edit <name of the FortiLink interface>
 set fortilink-split-interface enable
 end
```

- The default value for DHCP snooping on the FortiLink VLAN (system interface) is changed from “enabled” in FortiOS 5.6.2 and earlier to “disabled” in FortiOS 5.6.3 and later. Note that, in the GUI, DHCP snooping is automatically changed to “enable” when the DHCP server is enabled on the interface.

## Before you begin

Before you configure the managed FortiSwitch unit, the following assumptions have been made in the writing of this manual:

- You have completed the initial configuration of the FortiSwitch unit, as outlined in the QuickStart Guide for your FortiSwitch, and you have administrative access to the FortiSwitch Web-based manager and CLI.
- You have installed a FortiGate unit on your network and have administrative access to the FortiGate Web-based manager and CLI.

## How this guide is organized

This guide contains the following sections:

- [Connecting FortiLink ports](#) - information about connecting FortiSwitch ports to FortiGate ports.
- [FortiLink configuration using the FortiGate GUI](#)
- [FortiLink configuration using the FortiGate CLI](#)
- [Network topologies for managed FortiSwitches](#) - describes the configuration for various stacking topologies.
- [Optional setup tasks](#) - describes other setup tasks.
- [FortiSwitch features configuration](#) - describes configuring managed FortiSwitch features including VLANs.
- [FortiSwitch port features](#) - configure ports and PoE from the FortiGate unit.
- [FortiSwitch port security policy](#) - describes setting up FortiSwitch security policies.
- [Additional capabilities](#) - describes extra FortiSwitch features.
- [Troubleshooting](#) - describes techniques for troubleshooting common problems.

## Connecting FortiLink ports

This section contains information about the FortiSwitch and FortiGate ports that you connect to establish a FortiLink connection.

For all FortiGate models, you can connect up to 16 FortiSwitches to one FortiGate unit.

In FortiSwitchOS 3.3.0 and later releases, you can use any of the switch ports for FortiLink. Some or all of the switch ports (depending on the model) support auto-discovery of the FortiLink ports.

You can choose to connect a single FortiLink port or multiple FortiLink ports as a logical interface (link-aggregation group, hardware switch, or software switch).

### 1. Enable the switch controller on FortiGate

Before connecting the FortiSwitch and FortiGate units, ensure that the switch controller feature is enabled on the FortiGate with the FortiGate Web-based manager or CLI to enable the switch controller. Depending on the FortiGate model and software release, this feature may be enabled by default.

#### Using the FortiGate GUI

1. Go to **System > Feature Visibility**.
2. Turn on the **Switch Controller** feature, which is in the **Basic Features** list.
3. Select **Apply**.

The menu option **WiFi & Switch Controller** now appears.

#### Using the FortiGate CLI

Use the following commands to enable the Switch Controller:

```
config system global
 set switch-controller enable
end
```

### 2. Connect the FortiSwitch and FortiGate

FortiSwitchOS 3.3.0 and later provides flexibility for FortiLink:

- Use any switch port for FortiLink
- Provides auto-discovery of the FortiLink ports on the FortiSwitch
- Choice of a single FortiLink port or multiple FortiLink ports in a link-aggregation group (LAG)

#### Auto-discovery of the FortiSwitch ports

In FortiSwitchOS 3.3.0 and later releases, D-series FortiSwitch models support FortiLink auto-discovery, on automatic detection of the port connected to the FortiGate.

You can use any of the switch ports for FortiLink. Before connecting the switch to the FortiGate, use the following FortiSwitch CLI commands to configure a port for FortiLink auto-discovery:

```
config switch interface
```

```
edit <port>
set auto-discovery-fortilink enable
end
```

By default, each FortiSwitch model provides a set of ports that are enabled for FortiLink auto-discovery. If you connect the FortiLink using one of these ports, no switch configuration is required.

In FortiSwitchOS 3.4.0 and later releases, the last four ports are the default auto-discovery FortiLink ports. You can also run the **show switch interface** command on the FortiSwitch to see the ports that have auto-discovery enabled.

The following table lists the default auto-discovery ports for each switch model. **NOTE:** Any port can be used for FortiLink if it is manually configured.

| FortiSwitch Model                                         | Default Auto-FortiLink ports                     |
|-----------------------------------------------------------|--------------------------------------------------|
| FS-108D                                                   | ports 9 and 10                                   |
| FS-108D-POE                                               | ports 9 and 10                                   |
| FSR-112D                                                  | ports 9, 10, 11 and 12                           |
| FSR-112D-POE                                              | ports 5, 6, 7, 8, 9, 10, 11, and 12              |
| FS-124D, FS-124D-POE                                      | ports 23, 24, 25, and 26                         |
| FS-224D-POE                                               | ports 21, 22, 23, and 24                         |
| FS-224D-FPOE                                              | ports 21, 22, 23, 24, 25, 26, 27, and 28         |
| FS-248D, FS-248D-FPOE, FS-448D, FS-448D-FPOE, FS-448D-POE | ports 45, 46, 47, 48, 49, 50, 51, and 52         |
| FS-248D-POE                                               | ports 47, 48, 49, and 50                         |
| FS-424D, FS-424D-POE, FS-424D-FPOE                        | ports 23, 24, 25, and 26                         |
| FS-524D, FS-524D-FPOE                                     | ports 21, 22, 23, 24, 25, 26, 27, 28, 29, and 30 |
| FS-548D, FS-548D-FPOE                                     | ports 45, 46, 47, 48, 49, 50, 51, 52, 53, and 54 |
| FS-1024D, FS-1048D, FS-3032D                              | all ports                                        |

### Choosing the FortiGate ports

The FortiGate manages all of the switches through one active FortiLink. The FortiLink may consist of one port or multiple ports (for a LAG).

As a general rule, FortiLink is supported on all ports that are not listed as HA ports.

## FortiLink configuration using the FortiGate GUI

This section describes how to configure a FortiLink between a FortiSwitch and a FortiGate.

You can configure FortiLink using the FortiGate GUI or CLI. Fortinet recommends using the GUI because the CLI procedures are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with no configuration steps on the FortiSwitch and with a few simple configuration steps on the FortiGate.

### Summary of the procedure

1. On the FortiGate, configure the FortLink port or create a logical FortLink interface.
2. Authorize the managed FortiSwitch.

### Configure FortiLink as a single link

**To configure the FortiLink port on the FortiGate:**

1. Go to **Network > Interfaces**.
2. (Optional) If the FortiLink physical port is currently included in the internal interface, edit it and remove the desired port from the Physical Interface Members.
3. Edit the FortiLink port.
4. Set **Addressing mode** to **Dedicated to FortiSwitch**.
5. Configure the **IP/Network Mask** for your network.
6. Optionally select **Automatically authorize devices** or disable to manually authorize the FortiSwitch.
7. Select **OK**.

### Configure FortiLink as a logical interface

You can configure the FortiLink as a logical interface: link-aggregation group (LAG), hardware switch, or software switch).

LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate to the FortiSwitch. Ensure that you configure auto-discovery on the FortiSwitch ports (unless it is so by default).

1. Go to **Network > Interfaces**.
2. (Optional) If the FortiLink physical ports are currently included in the internal interface, edit the internal interface, and remove the desired ports from the Physical Interface Members.
3. Select **Create New > Interface**.
4. Enter a name for the interface (11 characters maximum).
5. Set the **Type** to **802.3ad Aggregate, Hardware Switch**, or **Software Switch**.
6. Select the FortiGate ports for the logical interface.
7. Set **Addressing mode** to **Dedicated to FortiSwitch**.
8. Configure the **IP/Network Mask** for your network.

9. Optionally select **Automatically authorize devices** or disable to manually authorize the FortiSwitch.
10. Select **OK**.

## FortiLink split interface

You can use the FortiLink split interface to connect the FortiLink aggregate interface from one FortiGate to two FortiSwitches. When the FortiLink split interface is enabled, only one link remains active.

The aggregate interface for this configuration must contain exactly two physical ports (one for each FortiSwitch).

You must enable the split interface on the FortiLink aggregate interface using the FortiGate CLI:

```
config system interface
 edit <name of the FortiLink interface>
 set fortilink-split-interface enable
 end
```

## Authorizing the FortiSwitch

If you configured the FortiLink interface to manually authorize the FortiSwitch as a managed switch, perform the following steps:

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Optionally, click on the FortiSwitch faceplate and click **Authorize**. This step is required only if you disabled the automatic authorization field of the interface.

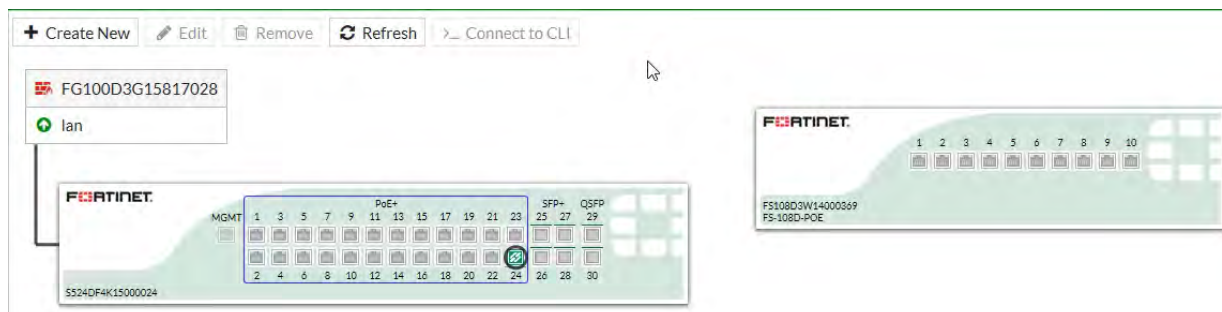

## Adding preauthorized FortiSwitches

After you preauthorize a FortiSwitch, you can assign the FortiSwitch ports to a VLAN.

**To preauthorize a FortiSwitch:**

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click **Create New**.
3. In the New Managed FortiSwitch page, enter the serial number, model name, and description of the FortiSwitch.
4. Move the **Authorized** slider to the right.
5. Click **OK**.

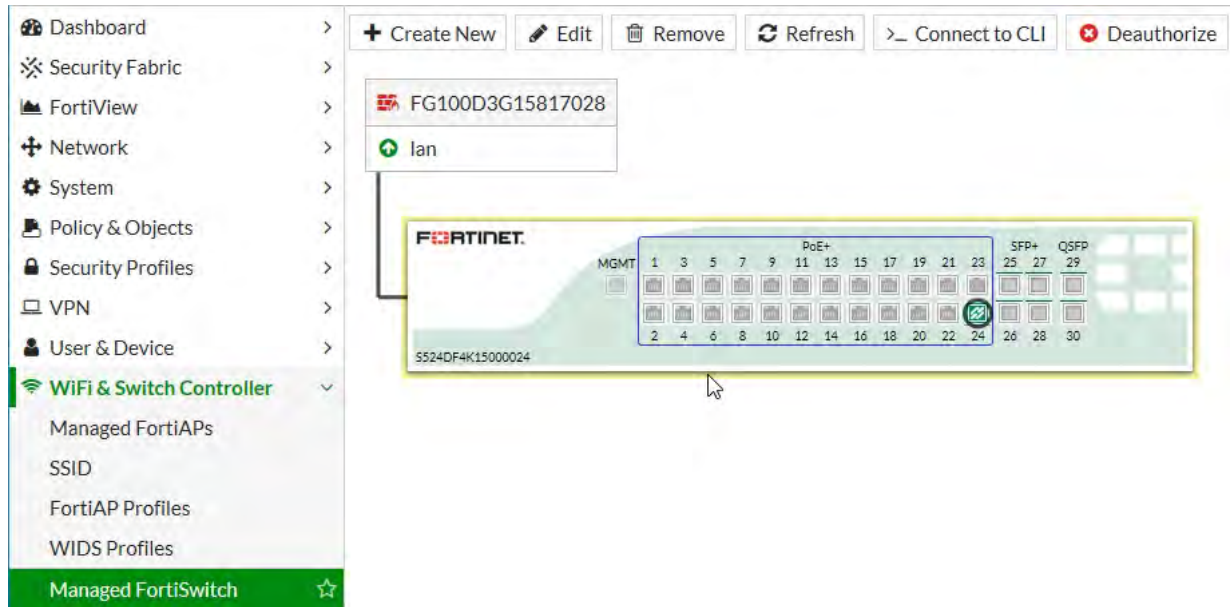

The Managed FortiSwitch page shows a FortiSwitch faceplate for the preauthorized switch.

## Managed FortiSwitch display

Go to **WiFi & Switch Controller > Managed FortiSwitch** to see all of the switches being managed by your FortiGate.

When the FortiLink is established successfully, the status is green (next to the FortiGate interface name and on the FortiSwitch faceplate), and the link between the ports is a solid line.

If the link has gone down for some reason, the line will be dashed, and a broken link icon will appear. You can still edit the FortiSwitch though and find more information about the status of the switch. The link to the FortiSwitch may be down for a number of reasons; for example, a problem with the cable linking the two devices, firmware versions being out of synch, and so on. You need to make sure the firmware running on the FortiSwitch is compatible with the firmware running on the FortiGate.

From the Managed FortiSwitch page, you can edit any of the managed FortiSwitches, remove a FortiSwitch from the configuration, refresh the display, connect to the CLI of a FortiSwitch, or deauthorize a FortiSwitch.

## Edit a managed FortiSwitch

**To edit a managed FortiSwitch:**

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click on the FortiSwitch to and click **Edit**, right-click on a FortiSwitch and select **Edit**, or double-click on a FortiSwitch.

From the **Edit Managed FortiSwitch** form, you can:

- Change the **Name** and **Description** of the FortiSwitch.
- View the **Status** of the FortiSwitch.
- **Restart** the FortiSwitch.

- **Authorize** or deauthorize the FortiSwitch.
- **Update** the firmware running on the switch.

## Network interface display

On the **Network > Interfaces** page, you can see the FortiGate interface connected to the FortiSwitch. The GUI indicates **Dedicated to FortiSwitch** in the IP/Netmask field.

| Status       | Name                               | Members | IP/Netmask                  | Type               | Access      | Ref. |
|--------------|------------------------------------|---------|-----------------------------|--------------------|-------------|------|
| Physical (4) |                                    |         |                             |                    |             |      |
| ↑            | port1                              |         | 172.20.121.31 255.255.255.0 | Physical Interface | PING HTTPS  | 2    |
| ↑            | port2                              |         | 1.1.1.1 255.255.255.0       | Physical Interface |             | 2    |
| ↑            | port3 (1 Connected FortiSwitch(s)) |         | Dedicated to FortiSwitch    | Physical Interface | PING CAPWAP | 3    |
|              | vsw.port3                          |         | 0.0.0.0 0.0.0.0             | VLAN               |             | 10   |

## Add link aggregation groups (Trunks)

To create a link aggregation group for FortiSwitch user ports:

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**.
2. Click **Create New > Trunk**.
3. In the New Trunk Group page, enter a **Name** for the trunk group.
4. Select two or more physical ports to add to the trunk group.
5. Select the **Mode**: Static, Passive LACP, or Active LACP.
6. Click **OK**.

**New Trunk Group**

Name: MyTrunk

Members: port1, port2, port3

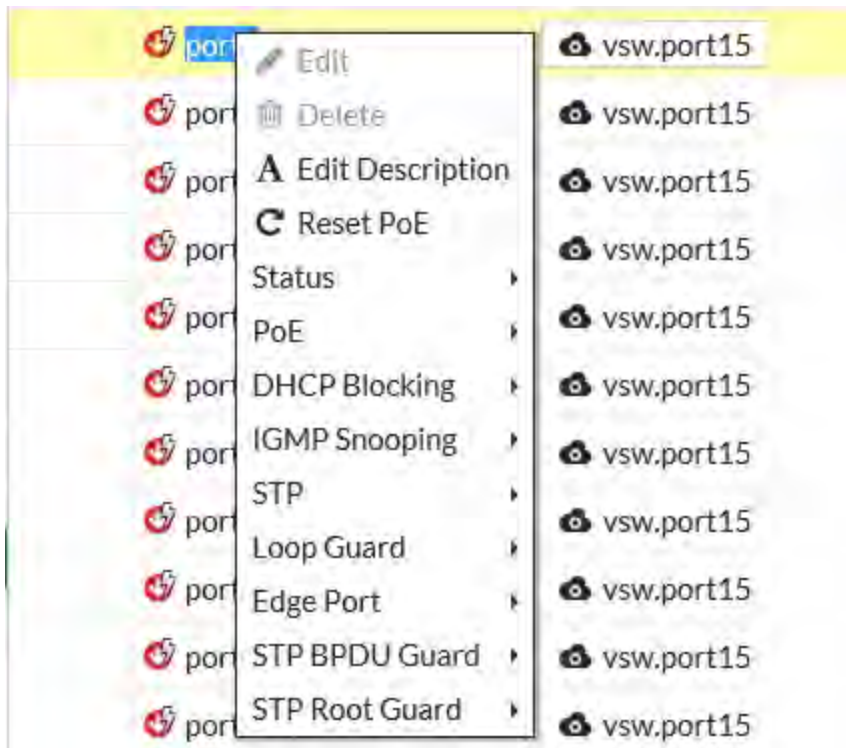

Mode: Static, Passive LACP, Active LACP

## Configure DHCP blocking, IGMP snooping, STP, and loop guard on managed FortiSwitch ports

Go to **WiFi & Switch Controller > FortiSwitch Ports**. Right-click any port and then enable or disable the following features:

- **DHCP blocking**—The DHCP blocking feature monitors the DHCP traffic from untrusted sources (for example, typically host ports and unknown DHCP servers) that might initiate traffic attacks or other hostile actions. To prevent this, DHCP blocking filters messages on untrusted ports.
- **IGMP snooping**—IGMP snooping allows the FortiSwitch to passively listen to the Internet Group Management Protocol (IGMP) network traffic between hosts and routers. The switch uses this information to determine which ports are interested in receiving each multicast feed. FortiSwitch can reduce unnecessary multicast traffic on the LAN by pruning multicast traffic from links that do not contain a multicast listener.
- **Spanning Tree Protocol (STP)**—STP is a link-management protocol that ensures a loop-free layer-2 network topology.
- **Loop guard**—A loop in a layer-2 network results in broadcast storms that have far-reaching and unwanted effects. Fortinet loop guard helps to prevent loops. When loop guard is enabled on a switch port, the port monitors its subtending network for any downstream loops. The loop guard feature is designed to work in concert with STP rather than as a replacement for STP.
- **STP root guard**—Root guard protects the interface on which it is enabled from becoming the path to root. When enabled on an interface, superior BPDUs received on that interface are ignored or dropped. Without using root guard, any switch that participates in STP maintains the ability to reroute the path to root. Rerouting might cause your network to transmit large amounts of traffic across suboptimal links or allow a malicious or misconfigured device to pose a security risk by passing core traffic through an insecure device for packet capture or inspection. By enabling root guard on multiple interfaces, you can create a perimeter around your existing paths to root to enforce the specified network topology.
- **STP BPDU guard**—Similar to root guard, BPDU guard protects the designed network topology. When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

STP is enabled on all ports by default. Loop guard is disabled by default on all ports.

## FortiLink configuration using the FortiGate CLI

This section describes how to configure FortiLink using the FortiGate CLI. Fortinet recommends using the FortiGate GUI because the CLI procedures are more complex (and therefore more prone to error).

If you use one of the auto-discovery FortiSwitch ports, you can establish the FortiLink connection (single port or LAG) with no configuration steps on the FortiSwitch and with a few simple configuration steps on the FortiGate.

### Summary of the procedure

1. Remove the port(s) from the LAN interface.
2. Configure the FortiLink port or create a logical FortiLink interface if it is required on the model you are using.
3. Configure NTP.
4. Authorize the managed FortiSwitch.
5. Configure DHCP.

### Configure FortiLink as a single link

Configure the FortiLink port on the FortiGate and authorize the FortiSwitch as a managed switch.

In the following steps, port 1 is configured as the FortiLink port.

1. If required, remove port 1 from the **lan** interface:

```
config system virtual-switch
 edit lan
 config port
 delete port1
 end
 end
end
```

2. Configure port 1 as the FortiLink interface:

```
config system interface
 edit port1
 set auto-auth-extension-device enable
 set fortilink enable
 end
end
```

3. Configure an NTP server on port 1:

```
config system ntp
 set server-mode enable
 set interface port1
end
```

4. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
 edit FS224D3W14000370
 set fsw-wan1-admin enable
 end
```

```
end
```

**NOTE:** FortiSwitch will reboot when you issue the **set fsw-wan1-admin enable** command.

## Configure FortiLink as a logical interface

You can configure the FortiLink as a logical interface: link-aggregation group (LAG), hardware switch, or software switch).

**NOTE:** LAG is supported on all FortiSwitch models and on FortiGate models FGT-100D and above. Hardware switch is supported on some FortiGate models.

Connect any of the FortiLink-capable ports on the FortiGate to the FortiSwitch. Ensure that you configure auto-discovery on the FortiSwitch ports (unless it is auto-discovery by default).

In the following procedure, port 4 and port 5 are configured as a FortiLink LAG.

1. If required, remove the FortiLink ports from the **lan** interface:

```
config system virtual-switch
 edit lan
 config port
 delete port4
 delete port5
 end
 end
end
```

2. Create a trunk with the two ports that you connected to the switch:

```
config system interface
 edit flink1 (enter a name, 11 characters maximum)
 set allowaccess ping capwap https
 set vlanforward enable
 set type aggregate
 set member port4 port5
 set lacp-mode static
 set fortilink enable
 (optional) set fortilink-split-interface enable
 next
end
```

**NOTE:** If the members of the aggregate interface connect to more than one FortiSwitch, you must enable **fortilink-split-interface**.

3. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
 edit FS224D3W14000370
 set fsw-wan1-admin enable
 end
end
```

**NOTE:** FortiSwitch will reboot when you issue the **set fsw-wan1-admin enable** command.

## Network topologies for managed FortiSwitches

The FortiGate requires only one active FortiLink to manage all of the subtending FortiSwitches (called *stacking*).

You can configure the FortiLink as a physical interface or as a logical interface (associated with one or more physical interfaces). Depending on the network topology, you may also configure a standby FortiLink.

For any of the topologies, note the following:

- All of the managed FortiSwitches will function as one Layer-2 stack where the FortiGate manages each FortiSwitch separately.
- The active FortiLink carries data as well as management traffic.

### Supported topologies

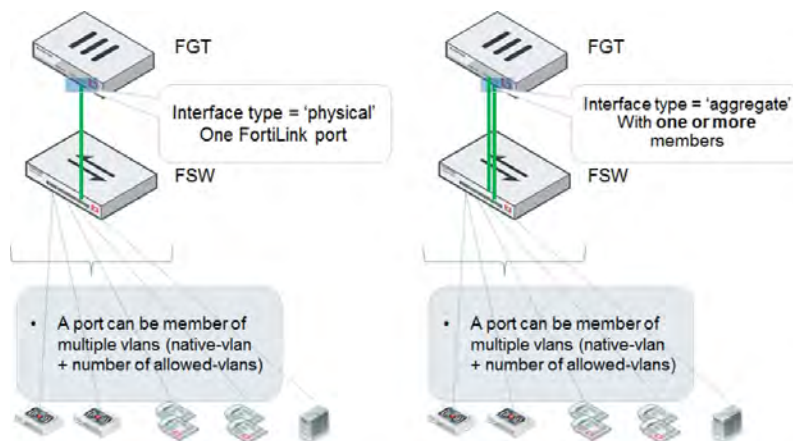

Fortinet recommends the following topologies for managed FortiSwitches:

- Single FortiGate managing a single FortiSwitch
- Single FortiGate managing a stack of several FortiSwitches
- HA-mode FortiGates managing a single FortiSwitch
- HA-mode FortiGates managing a stack of several FortiSwitches
- HA-mode FortiGates managing a FortiSwitch two-tier topology
- Single FortiGate managing multiple FortiSwitches (using a hardware or software switch interface)
- HA-mode FortiGates managing two-tier FortiSwitches with access rings
- Dual-homed servers connected to FortiLink tier-1 FortiSwitches using an MCLAG
- Standalone FortiGate with dual-homed FortiSwitch access
- HA-mode FortiGates with dual-homed FortiSwitch access

### Single FortiGate managing a single FortiSwitch

On the FortiGate, the FortiLink interface is configured as physical or aggregate. The 802.3ad aggregate interface type provides a logical grouping of one or more physical interfaces.

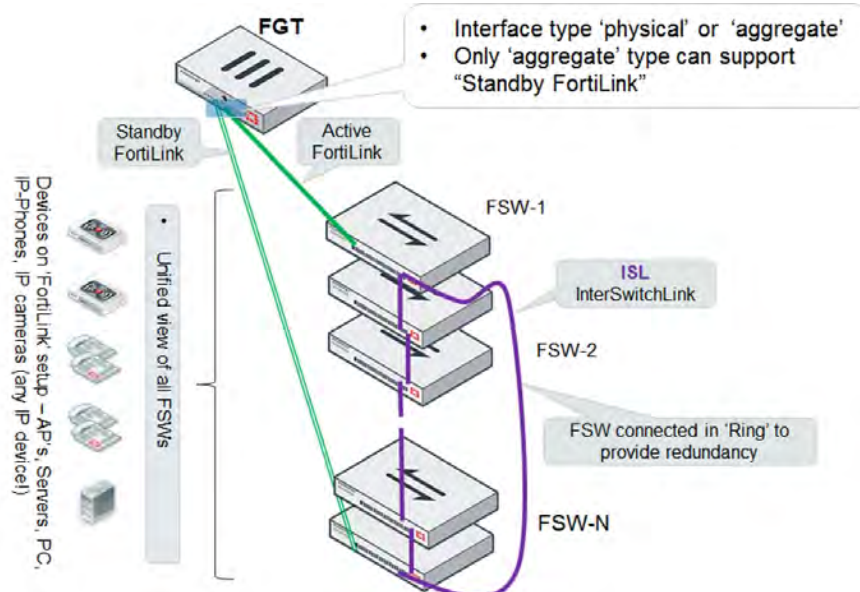

**NOTE:** For the aggregate interface, you must disable the split interface on the FortiGate.

## Single FortiGate managing a stack of several FortiSwitches

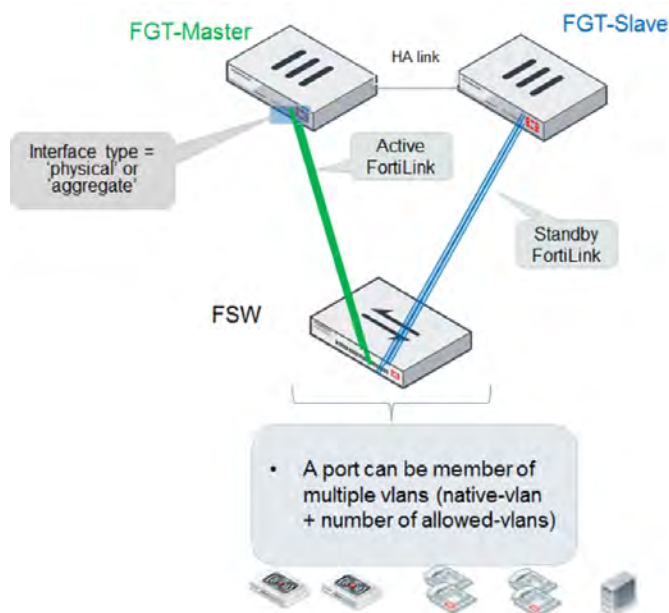

The FortiGate connects directly to one FortiSwitch device using a physical or aggregate interface. The remaining FortiSwitches connect in a ring using inter-switch links (that is, ISL).

Optionally, you can connect a standby FortiLink connection to the last FortiSwitch. For this configuration, you create a FortiLink Split-Interface (an aggregate interface that contains one active link and one standby link).

## HA-mode FortiGates managing a single FortiSwitch

The master and slave FortiGate units both connect a FortiLink to the FortiSwitch. The FortiLink port(s) and interface type must match on the two FortiGate units.

## HA-mode FortiGates managing a stack of several FortiSwitches

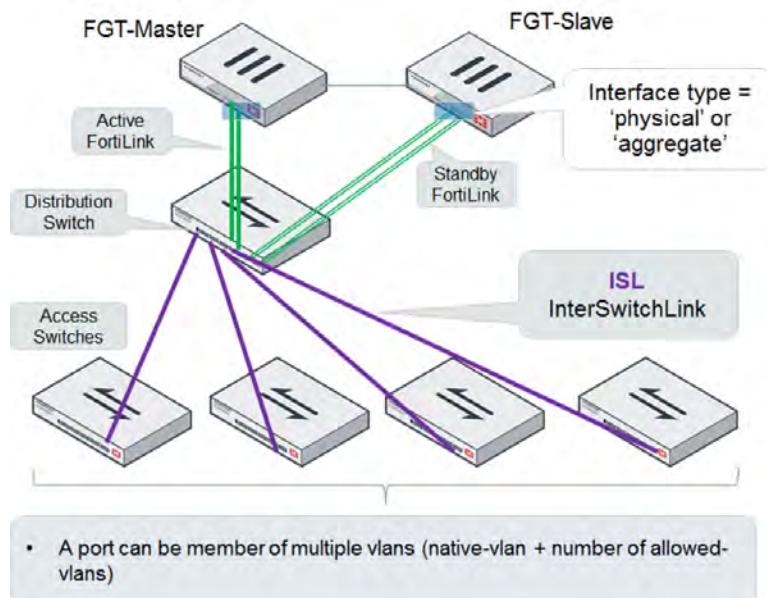

The master and slave FortiGate units both connect a FortiLink to the first FortiSwitch and (optionally) to the last FortiSwitch. The FortiLink ports and interface type must match on the two FortiGate units.

For the active/standby FortiLink configuration, you create a FortiLink Split-Interface (an aggregate interface that contains one active link and one standby link).

## HA-mode FortiGates managing a FortiSwitch two-tier topology

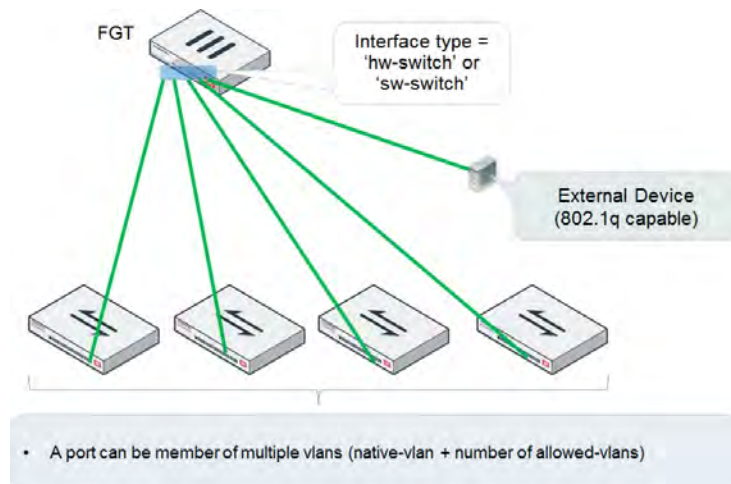

The distribution FortiSwitch connects to the master and slave FortiGate units. The FortiLink port(s) and interface type must match on the two FortiGate units.

## Single FortiGate managing multiple FortiSwitches (using a hardware or software switch interface)

The FortiGate connects directly to each FortiSwitch. Each of these FortiLink ports is added to the logical hardware-switch or software-switch interface on the FortiGate.

Optionally, you can connect other devices to the FortiGate logical interface. These devices, which must support IEEE 802.1q VLAN tagging, will have Layer 2 connectivity with the FortiSwitch ports.

**NOTE:** Using the hardware or software switch interface in FortiLink mode is not recommended in most cases. It can be used when the traffic on the ports is very light because all traffic across the switches moves through FortiGate.

## HA-mode FortiGates managing two-tier FortiSwitches with access rings

**NOTE:** MCLAG is not supported when access rings are present.

HA-mode FortiGates connect to redundant distribution FortiSwitches. Access FortiSwitches are arranged in a stack in each IDF, connected to both distribution switches.

For the FortiLink connection to each distribution switch, you create a FortiLink split interface (an aggregate interface that contains one active link and one standby link).

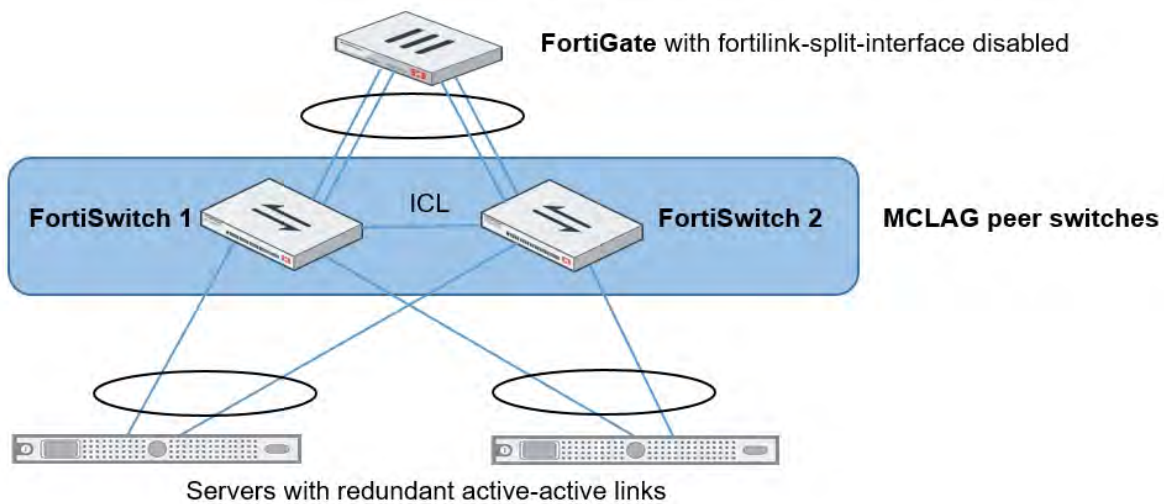

## Dual-homed servers connected to FortiLink tier-1 FortiSwitches using an MCLAG

To configure a multichassis LAG, you need to configure FortiSwitch 1 and FortiSwitch 2 as MCLAG peer switches before creating a two-port LAG. Use the `set mclag-icl enable` command to create an inter-chassis link (ICL) on each FortiSwitch. Then you set up two MCLAGs towards the servers, each MCLAG using one port from each FortiSwitch. You must disable the FortiLink split interface for the FortiGate.

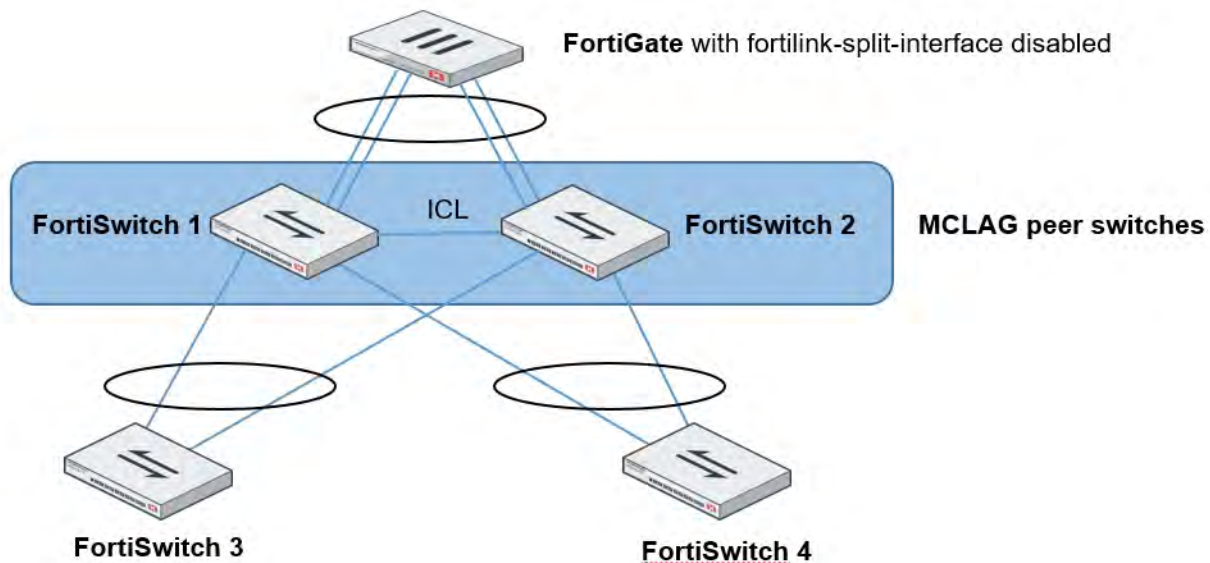

This topology is supported when the FortiGate is in HA mode.

## Standalone FortiGate with dual-homed FortiSwitch access

This network topology provides high port density with two tiers of FortiSwitches.

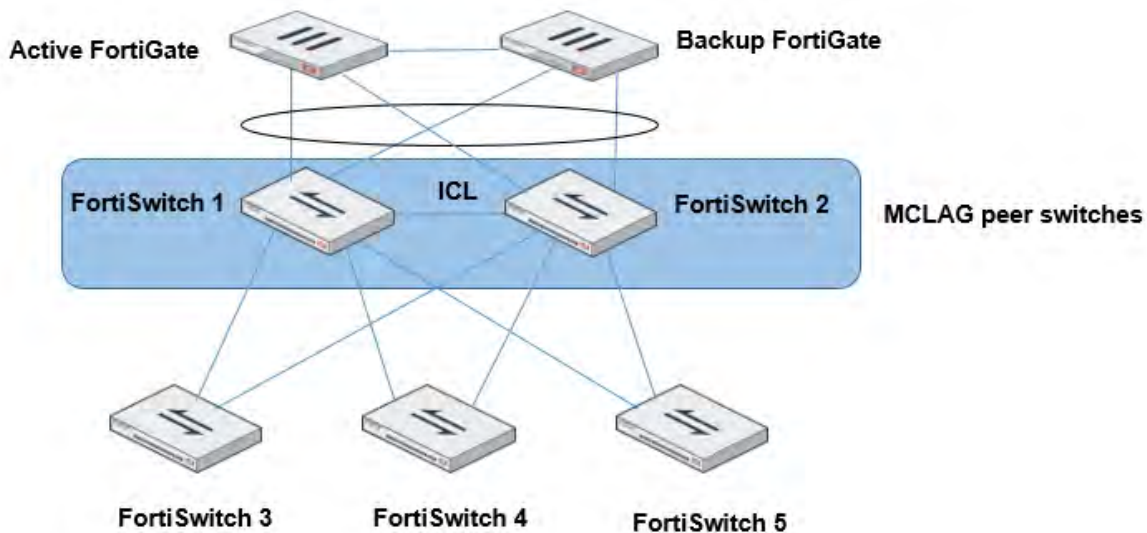

Use the `set mclag-icl enable` command to create an ICL on each FortiSwitch.

## HA-mode FortiGates with dual-homed FortiSwitch access

In HA mode, only one FortiGate is active at a time. If the active FortiGate fails, the backup FortiGate becomes active.

Use the `set mclag-icl enable` command to create an ICL on each FortiSwitch.

## Grouping FortiSwitches

You can simplify the configuration and management of complex topologies by creating FortiSwitch groups. A group can include one or more FortiSwitches and you can include different models in a group.

```
config switch-controller switch-group
 edit <name>
 set description <string>
 set members <serial-number> <serial-number> ...
 end
end
```

Grouping FortiSwitches allows you to restart all of the switches in the group instead of individually. For example, you can use the following command to restart all of the FortiSwitches in a group named `my-sw-group`:

```
execute switch-controller restart-swtp my-switch-group
```

Upgrading the firmware of FortiSwitch groups is easier, too, because fewer commands are needed. See [Firmware upgrade of stacked or tiered FortiSwitches on page 2380](#).

## Stacking configuration

### To set up stacking:

1. Configure the active FortiLink interface on the FortiGate.
2. (Optional) Configure the standby FortiLink interface.
3. Connect the FortiSwitches together, based on your chosen topology.

### 1. Configure the active FortiLink

Configure the FortiLink interface (as described in the [FortiLink configuration using the FortiGate GUI](#) chapter).

When you configure the FortiLink interface, the stacking capability is enabled automatically.

### 2. Configure the standby FortiLink

Configure the standby FortiLink interface. Depending on your configuration, the standby FortiLink might connect to the same FortiGate as the active FortiLink or to a different FortiGate.

If the FortiGate receives discovery requests from two FortiSwitches, the link from one FortiSwitch will be selected as active, and the link from other FortiSwitch will be selected as standby.

If the active FortiLink fails, FortiGate converts the standby FortiLink to active.

### 3. Connect the FortiSwitches

Refer to the topology diagrams to see how to connect the FortiSwitches.

Inter-switch links (ISLs) form automatically between the stacked switches.

FortiGate will discover and authorize all of the FortiSwitches that are connected. After this, the FortiGate is ready to manage all of the authorized FortiSwitches.

### Disable stacking

To disable stacking, execute the following commands from the FortiGate CLI. In the following example, port4 is the FortiLink interface:

```
config system interface
 edit port4
 set fortilink-stacking disable
 end
end
```

## Firmware upgrade of stacked or tiered FortiSwitches

In this topology, the core FortiSwitches are model FS-224D-FPOE, and the access FortiSwitches are model FS-124D-POE. Because the switches are stacked or tiered, the procedure to update the firmware is simpler. In the following procedure, the four FortiSwitches are upgraded from 3.6.1 to 3.6.2.

### To upgrade the firmware of stacked or tiered FortiSwitches:

1. Check that all of the FortiSwitches are connected and which firmware versions they are running. For example:

```
FG100E4Q16004478 (root) # execute switch-controller get-conn-status
Managed-devices in current vdom root:

STACK-NAME: FortiSwitch-Stack-flink
SWITCH-ID VERSION STATUS ADDRESS JOIN-TIME
NAME
S124DP3X15000118 v3.6.1 Authorized/Up 169.254.1.5 Mon Oct 2 14:06:08 2017 -
S124DP3X15000380 v3.6.1 Authorized/Up 169.254.1.4 Mon Oct 2 14:05:26 2017 -
S224DF3X16001718 v3.6.1 Authorized/Up 169.254.1.3 Mon Oct 2 14:05:37 2017 -
S224DF3X17000238 v3.6.1 Authorized/Up 169.254.1.2 Mon Oct 2 14:06:22 2017 -
```

2. Upload the firmware image for each FortiSwitch model (FS-224D-FPOE and FS-124D-POE) from either an FTP or TFTP server. If you are using a virtual domain (VDM), you must enter the `config global` command before entering the `upload-swtp-image` command. For example:

```
FG100E4Q16004478 (global) # execute switch-controller upload-swtp-image tftp FSW_124D_POE-
v3-build0382-FORTINET.out 172.30.12.18

Downloading file FSW_124D_POE-v3-build0382-FORTINET.out from tftp server 172.30.12.18...
#####
Image checking ...
Image MD5 calculating ...
Image Saving S124DP-IMG.swtp ...
Successful!

File Syncing...

FG100E4Q16004478 (global) # execute switch-controller upload-swtp-image tftp FSW_224D_FPOE-
v3-build0382-FORTINET.out 172.30.12.18

Downloading file FSW_224D_FPOE-v3-build0382-FORTINET.out from tftp server 172.30.12.18...
#####
Image checking ...
Image MD5 calculating ...
Image Saving S224DF-IMG.swtp ...
Successful!

File Syncing...
```

3. Check which firmware images are available. For example:

```
FG100E4Q16004478 (root) # execute switch-controller list-swtp-image
SWTP Images on AC:
ImageName ImageSize(B) ImageInfo ImageMTime
S124DP-IMG.swtp 19174985 S124DP-v3.6-build382 Mon Oct 2 14:40:54 2017
S224DF-IMG.swtp 23277106 S224DF-v3.6-build382 Mon Oct 2 14:42:55 2017
```

4. Stage the firmware image for each FortiSwitch model (FS-224D-FPOE and FS-124D-POE). For example:

```
FG100E4Q16004478 (root) # execute switch-controller stage-tiered-swtp-image ALL S124DP-
IMG.swtp
Staged Image Version S124DP-v3.6-build382

FG100E4Q16004478 (root) # execute switch-controller stage-tiered-swtp-image ALL S224DF-
IMG.swtp
Staged Image Version S224DF-v3.6-build382
```

5. Check that the correct firmware image is staged for each FortiSwitch. For example:

```
FG100E4Q16004478 (root) # diagnose switch-controller dump network-upgrade status
Device State

=====
VDM : root
S224DF3X16001718 Running : S224DF-v3.6.1-build372,170620 (GA)
Next Boot : S224DF-v3.6-build382, Flash Erase:[100], Flash Write:[100]
S224DF3X17000238 Running : S224DF-v3.6.1-build372,170620 (GA)
Next Boot : S224DF-v3.6-build382, Flash Erase:[100], Flash Write:[100]
S124DP3X15000118 Running : S124DP-v3.6.1-build372,170620 (GA)
Next Boot : S124DP-v3.6-build382, Flash Erase:[100], Flash Write:[100]
S124DP3X15000380 Running : S124DP-v3.6.1-build372,170620 (GA)
Next Boot : S124DP-v3.6-build382, Flash Erase:[100], Flash Write:[100]
```

6. Restart the FortiSwitches after a 2-minute delay. For example:

```
execute switch-controller restart-swtp-delayed ALL
```

7. When the FortiSwitches are running again, check that they are running the new firmware version. For example:

```
execute switch-controller get-conn-status
Managed-devices in current vdom root:
```

```
STACK-NAME: FortiSwitch-Stack-flink
SWITCH-ID VERSION STATUS ADDRESS JOIN-TIME
NAME
S124DP3X15000118 v3.6.2 Authorized/Up 169.254.1.5 Mon Oct 2 15:26:51 2017 -
S124DP3X15000380 v3.6.2 Authorized/Up 169.254.1.4 Mon Oct 2 15:26:49 2017 -
S224DF3X16001718 v3.6.2 Authorized/Up 169.254.1.3 Mon Oct 2 15:25:44 2017 -
S224DF3X17000238 v3.6.2 Authorized/Up 169.254.1.2 Mon Oct 2 15:25:27 2017 -
```

## Transitioning from a FortiLink split interface to a FortiLink MCLAG

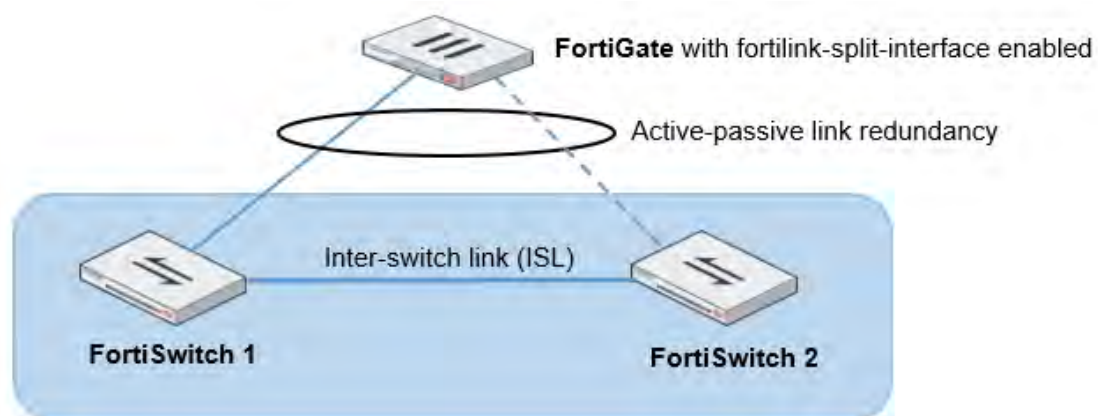

In this topology, the FortiLink split interface connects a FortiLink aggregate interface from one FortiGate to two FortiSwitches.

Note the following:

- This procedure also applies to a FortiGate in HA mode.
- More links can be added between the FortiGate and FortiSwitch.
- After the MCLAG is set up, only connect the tier-2 FortiSwitches.

1. Enable the split interface on the FortiLink aggregate interface. By default, the split interface is enabled. For example:

```
config system interface
edit flinksplit1
set ip 169.254.3.1 255.255.255.0
set allowaccess ping capwap https
set vlanforward enable
set type aggregate
set member port4 port5
set lacp-mode static
set fortilink enable
set fortilink-split-interface enable
next
end
```

2. Log into FortiSwitch 2 using the **Connect to CLI** button in the FortiGate GUI, use the `get switch lldp auto-isl-status` command to find out the name of the trunk connecting the peer switches, and change the ISL to an ICL. For example:

```
get switch lldp auto-isl-status

config switch trunk
 edit <trunk_name>
 set mclag-icl enable
 next
end
```

3. Log into FortiSwitch 1 using the **Connect to CLI** button in the FortiGate GUI, use the `get switch lldp auto-isl-status` command to find out the name of the trunk connecting the peer switches, and change the ISL to an ICL. For example:

```
get switch lldp auto-isl-status

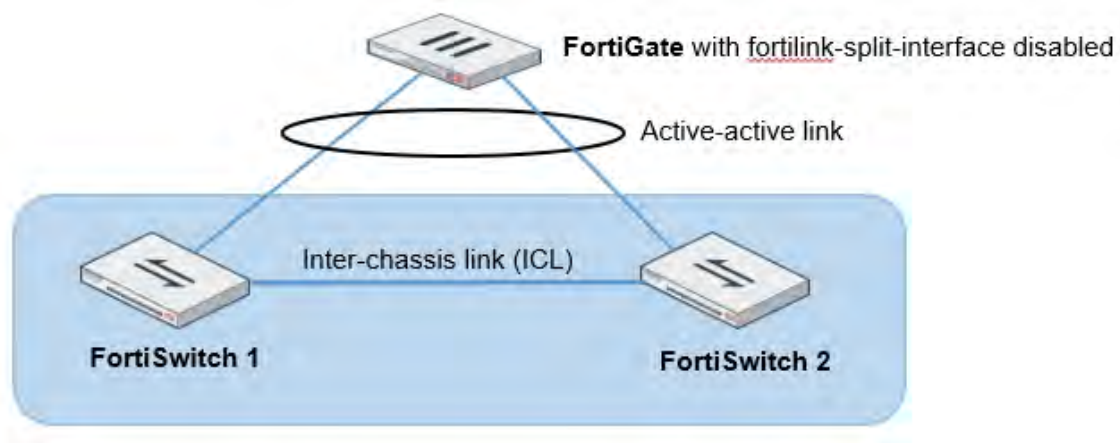

config switch trunk
 edit <trunk_name>
 set mclag-icl enable
 next
end
```

4. Log into the FortiGate and disable the split interface. For example:

```
config system interface
 edit flinksplit1
 set fortilink-split-interface disable
 next
end
```

5. Enable the LACP active mode.
6. Check that the LAG is working correctly. For example:

```
diagnose netlink aggregate name <aggregate_name>
```

## Optional setup tasks

This section describes the following tasks:

- Configuring the FortiSwitch management port
- Converting to the FortiSwitch standalone mode
- Changing the admin password on the FortiGate for all managed FortiSwitches

### Configuring the FortiSwitch management port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

#### Using the Web administration GUI

1. Go to **Network > Static Routes > Create New > Route**.
2. Set **Destination** to **Subnet** and enter a subnetwork and mask.
3. Set **Device** to the management interface.
4. Add a **Gateway** IP address.

#### Using the FortiSwitch CLI

Enter the following commands:

```
config router static
 edit 1
 set device mgmt
 set gateway <router IP address>
 set dst <router subnet> <subnet mask>
 end
end
```

In the following example, the FortiSwitch management port is connected to a router with IP address 192.168.0.10:

```
config router static
 edit 1
 set device mgmt
 set gateway 192.168.0.10
 set dst 192.168.0.0 255.255.0.0
 end
end
```

### Converting to FortiSwitch standalone mode

Use one of the following commands to convert a FortiSwitch from FortiLink mode to standalone mode so that it will no longer be managed by a FortiGate:

- `execute switch-controller factory-reset <switch-id>`  
This command returns the FortiSwitch to the factory defaults and then reboots the FortiSwitch. If the FortiSwitch is configured for FortiLink auto-discovery, FortiGate can detect and automatically authorize the FortiSwitch. For example:  
`execute switch-controller factory-reset S1234567890`
- `execute switch-controller set-standalone <switch-id>`  
This command returns the FortiSwitch to the factory defaults, reboots the FortiSwitch, and prevents the FortiGate from automatically detecting and authorizing the FortiSwitch. For example:  
`execute switch-controller set-standalone S1234567890`

You can disable FortiLink auto-discovery on multiple FortiSwitches using the following commands:

```
config switch-controller global
 set disable-discovery <switch-id>
end
```

For example:

```
config switch-controller global
 set disable-discovery S1234567890
end
```

You can also add or remove entries from the list of FortiSwitches that have FortiLink auto-discovery disabled using the following commands:

```
config switch-controller global
 append disable-discovery <switch-id>
 unselect disable-discovery <switch-id>
end
```

For example:

```
config switch-controller global
 append disable-discovery S012345678
 unselect disable-discovery S1234567890
end
```

## Changing the admin password on the FortiGate for all managed FortiSwitches

By default, each FortiSwitch has an admin account without a password. To replace the admin passwords for all FortiSwitches managed by a FortiGate, use the following commands from the FortiGate CLI:

```
config switch-controller switch-profile
 edit default
 set login-passwd-override {enable | disable}
 set login-passwd <password>
 next
end
```

If you had already applied a profile with the override enabled and the password set and then decide to remove the admin password, you need to apply a profile with the override enabled and no password set; otherwise, your previously set password will remain in the FortiSwitch. For example:

```
config switch-controller switch-profile
 edit default
```

```
 set login-passwd-override enable
 unset login-passwd
 next
end
```

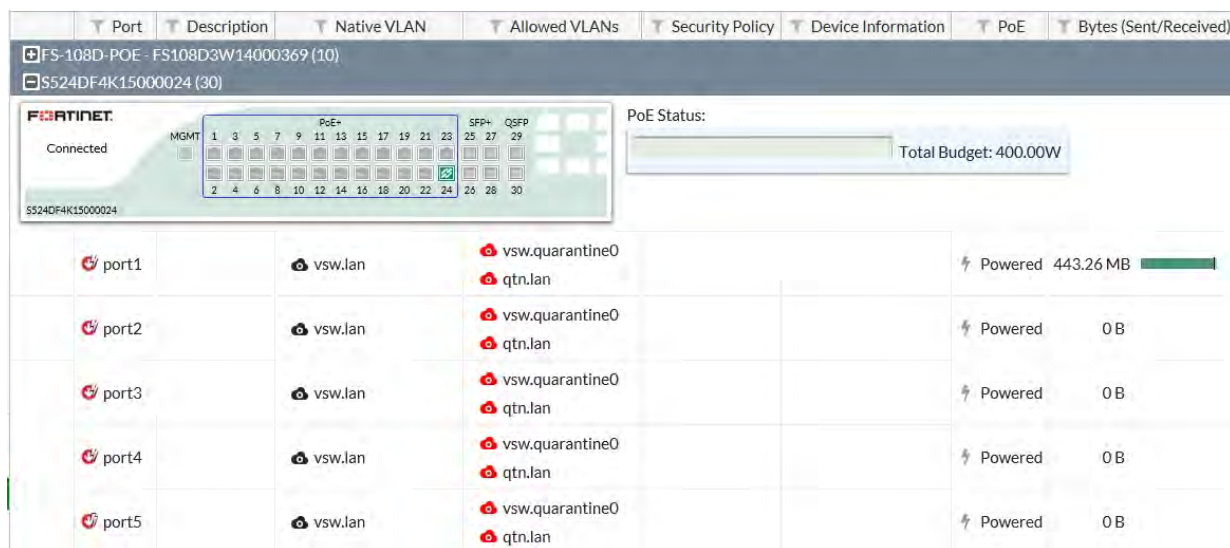

## FortiSwitch port features

You can configure the FortiSwitch port feature settings from the FortiGate using the FortiSwitch CLI or Web administration GUI.

### FortiSwitch ports display

The **WiFi & Switch Controller > FortiSwitch Ports** page displays port information about each of the managed switches.

The following figure shows the display for a FortiSwitch 524D-FPOE:

The switch faceplate displays:

- active ports (green)
- PoE-enabled ports (blue rectangle)
- FortiLink port (link icon)

**PoE Status** displays the total power budget and the actual power currently allocated.

The allocated power displays a blue bar for the used power (currently being consumed) and a green bar for the reserved power (power available for additional devices on the POE ports). See the following figures:

Each entry in the port list displays the following information:

- Port status (red for down, green for up)
- Port name

- Native VLAN
- Allowed VLANs
- Device information
- PoE status
- Bytes sent and received by the port

## Configuring ports using the GUI

You can use the **WiFi & Switch Controller > FortiSwitch Ports** page to do the following with FortiSwitch switch ports:

- Set the native VLAN and add more VLANs
- Edit the description of the port
- Enable or disable the port
- Enable or disable PoE for the port
- Enable or disable DHCP blocking (if supported by the port)
- Enable or disable IGMP snooping (if supported by the port)
- Enable or disable whether a port is an edge port
- Enable or disable STP (if supported by the port)
- Enable or disable loop guard (if supported by the port)
- Enable or disable STP BPDU guard (if supported by the port)
- Enable or disable STP root guard (if supported by the port)

### Resetting PoE-enabled ports

If you need to reset PoE-enabled ports, go to **WiFi & Switch Control > FortiSwitch Ports**, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

You can also go to **WiFi & Switch Control > Managed FortiSwitch** and click on a port icon for the FortiSwitch of interest. In the FortiSwitch Ports page, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

## Configuring ports using the FortiGate CLI

You can configure the following FortiSwitch port settings using the FortiGate CLI:

- [Configuring port speed and status on page 2389](#)
- [Configure a VLAN on the port \(see \[VLAN Configuration\]\(#\)\)](#)
- [Configuring the DHCP trust setting on page 2389](#)
- [Configuring PoE on page 2389](#)
- [Configuring edge ports on page 2390](#)
- [Configuring STP on page 2391](#)
- [Configuring STP root guard on page 2392](#)
- [Configuring STP BPDU guard on page 2393](#)
- [Configuring loop guard on page 2394](#)
- [Configuring LLDP settings on page 2395](#)
- [Configuring IGMP settings on page 2395](#)

## Configuring port speed and status

Use the following commands to set port speed and other base port settings:

```
config switch-controller managed-switch
edit <switch>
config ports
edit <port>
set description <text>
set speed <speed>
set status {down | up}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set description "First port"
set speed auto
set status up
end
end
```

## Configuring the DHCP trust setting

The DHCP blocking feature monitors the DHCP traffic from untrusted sources (for example, typically host ports and unknown DHCP servers) that might initiate traffic attacks or other hostile actions. To prevent this, DHCP blocking filters messages on untrusted ports.

Set the port as a trusted or untrusted DHCP-snooping interface:

```
config switch-controller managed-switch
edit <switch-id>
config ports
edit <port name>
set dhcp-snooping {trusted | untrusted}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set dhcp-snooping trusted
end
end
```

## Configuring PoE

The following PoE CLI commands are available starting in FortiSwitchOS 3.3.0.

### Enable PoE on the port

```
config switch-controller managed-switch
edit <switch-id>
config ports
edit <port name>
set poe-status {enable | disable}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set poe-status enable
end
end
```

### Reset the PoE port

Power over Ethernet (PoE) describes any system that passes electric power along with data on twisted pair Ethernet cabling. Doing this allows a single cable to provide both data connection and electric power to devices (for example, wireless access points, IP cameras, and VoIP phones).

The following command resets PoE on the port:

```
execute switch-controller poe-reset <fortiswitch-id> <port>
```

### Display general PoE status

```
get switch-controller <fortiswitch-id> <port>
```

The following example displays the PoE status for port 6 on the specified switch:

```
get switch-controller poe FS108D3W14000967 port6
Port(6) Power:3.90W, Power-Status: Delivering Power
Power-Up Mode: Normal Mode
Remote Power Device Type: IEEE802.3AT PD
Power Class: 4
Defined Max Power: 30.0W, Priority:3
Voltage: 54.00V
Current: 78mA
```

### Configuring edge ports

Use the following commands to enable or disable an interface as an edge port:

```
config switch-controller managed-switch
edit <switch>
config ports
edit <port>
set edge-port {enable | disable}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set edge-port enable
end
end
```

## Configuring STP

Starting with FortiSwitch Release 3.4.2, STP is enabled by default for the non-FortiLink ports on the managed FortiSwitches. STP is a link-management protocol that ensures a loop-free layer-2 network topology.

To configure global STP settings, see [Configure STP settings on page 1](#).

Use the following commands to enable or disable STP on FortiSwitch ports:

```
config switch-controller managed-switch
edit <switch-id>
config ports
edit <port name>
set stp-state {enabled | disabled}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
set stp-state enabled
end
end
```

To check the STP configuration on a FortiSwitch, use the following command:

```
diagnose switch-controller dump stp <FortiSwitch_serial_number> <instance_number>
```

For example:

```
FG100D3G15817028 # diagnose switch-controller dump stp S524DF4K15000024 0

MST Instance Information, primary-Channel:

Instance ID : 0

Switch Priority : 24576

Root MAC Address : 085b0ef195e4
Root Priority: 24576
Root Pathcost: 0
Regional Root MAC Address : 085b0ef195e4
Regional Root Priority: 24576
Regional Root Path Cost: 0
Remaining Hops: 20
This Bridge MAC Address : 085b0ef195e4
This bridge is the root
```

| Port | Speed | Cost | Priority | Role | State | Edge | STP-Status | Loop |
|------|-------|------|----------|------|-------|------|------------|------|
|      |       |      |          |      |       |      |            |      |

## Protection

|                 |    |           |     |            |            |     |          |    |
|-----------------|----|-----------|-----|------------|------------|-----|----------|----|
| port1           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port2           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port3           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port4           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port5           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port6           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port7           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port8           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port9           | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port10          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port11          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port12          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port13          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port14          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port15          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port16          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port17          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port18          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port19          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port20          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port21          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port22          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port23          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port25          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port26          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port27          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port28          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port29          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |
| port30          | -  | 200000000 | 128 | DISABLED   | DISCARDING | YES | ENABLED  | NO |

## Configuring STP root guard

Root guard protects the interface on which it is enabled from becoming the path to root. When enabled on an interface, superior BPDUs received on that interface are ignored or dropped. Without using root guard, any switch that participates in STP maintains the ability to reroute the path to root. Rerouting might cause your network to transmit large amounts of traffic across suboptimal links or allow a malicious or misconfigured device to pose a security risk by passing core traffic through an insecure device for packet capture or inspection. By enabling root guard on multiple interfaces, you can create a perimeter around your existing paths to root to enforce the specified network topology.

Enable root guard on all ports that should not be root bridges. Do not enable root guard on the root port. You must have STP enabled to be able to use root guard.

Use the following commands to enable or disable STP root guard on FortiSwitch ports:

```
config switch-controller managed-switch
edit <switch-id>
config ports
edit <port name>
set stp-root-guard {enabled | disabled}
end
end
```

For example:

```
config switch-controller managed-switch
edit S524DF4K15000024
config ports
edit port1
```

```

 set stp-root-guard enabled
 end
end

```

## Configuring STP BPDU guard

Similar to root guard, BPDU guard protects the designed network topology. When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

There are two prerequisites for using BPDU guard:

- You must define the port as an edge port with the `set edge-port enable` command.
- You must enable STP on the switch interface with the `set stp-state enabled` command.

You can set how long the port will go down when a BPDU is received for a maximum of 120 minutes. The default port timeout is 5 minutes. If you set the timeout value to 0, the port will not go down when a BPDU is received, but you will have manually reset the port.

Use the following commands to enable or disable STP BPDU guard on FortiSwitch ports:

```

config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port name>
 set stp-bpdu-guard {enabled | disabled}
 set stp-bpdu-guard-time <0-120>
 end
 end
 end
end

```

For example:

```

config switch-controller managed-switch
 edit S524DF4K15000024
 config ports
 edit port1
 set stp-bpdu-guard enabled
 set stp-bpdu-guard-time 10
 end
 end
 end
end

```

To check the configuration of STP BPDU guard on a FortiSwitch, use the following command:

```
diagnose switch-controller dump bpdu-guard-status <FortiSwitch_serial_number>
```

For example:

```

FG100D3G15817028 # diagnose switch-controller dump bpdu-guard-status
S524DF4K15000024
Managed Switch : S524DF4K15000024 0

```

| Portname | State    | Status | Timeout (m) | Count | Last-Event |
|----------|----------|--------|-------------|-------|------------|
| port1    | enabled  | -      | 10          | 0     | -          |
| port2    | disabled | -      | -           | -     | -          |

|                 |          |   |   |   |   |
|-----------------|----------|---|---|---|---|
| port3           | disabled | - | - | - | - |
| port4           | disabled | - | - | - | - |
| port5           | disabled | - | - | - | - |
| port6           | disabled | - | - | - | - |
| port7           | disabled | - | - | - | - |
| port8           | disabled | - | - | - | - |
| port9           | disabled | - | - | - | - |
| port10          | disabled | - | - | - | - |
| port11          | disabled | - | - | - | - |
| port12          | disabled | - | - | - | - |
| port13          | disabled | - | - | - | - |
| port14          | disabled | - | - | - | - |
| port15          | disabled | - | - | - | - |
| port16          | disabled | - | - | - | - |
| port17          | disabled | - | - | - | - |
| port18          | disabled | - | - | - | - |
| port19          | disabled | - | - | - | - |
| port20          | disabled | - | - | - | - |
| port21          | disabled | - | - | - | - |
| port22          | disabled | - | - | - | - |
| port23          | disabled | - | - | - | - |
| port25          | disabled | - | - | - | - |
| port26          | disabled | - | - | - | - |
| port27          | disabled | - | - | - | - |
| port28          | disabled | - | - | - | - |
| port29          | disabled | - | - | - | - |
| port30          | disabled | - | - | - | - |
| __FoRtI1LiNk0__ | disabled | - | - | - | - |

## Configuring loop guard

A loop in a layer-2 network results in broadcast storms that have far-reaching and unwanted effects. Fortinet loop guard helps to prevent loops. When loop guard is enabled on a switch port, the port monitors its subtending network for any downstream loops. The loop guard feature is designed to work in concert with STP rather than as a replacement for STP. By default, loop guard is disabled on all ports.

Use the following commands to configure loop guard on a FortiSwitch port:

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port name>
 set loop-guard {enabled | disabled}
 set loop-guard-timeout <0-120 minutes>
 end
 end
 end
```

For example:

```
config switch-controller managed-switch
 edit S524DF4K15000024
 config ports
 edit port1
 set loop-guard enabled
 set loop-guard-timeout 10
 end
 end
```

```
end
```

## Configuring LLDP settings

The Fortinet data center switches support the Link Layer Discovery Protocol (LLDP) for transmission and reception wherein the switch will multicast LLDP packets to advertise its identity and capabilities. A switch receives the equivalent information from adjacent layer-2 peers.

Use the following commands to configure LLDP on a FortiSwitch port:

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port name>
 set lldp-status {rx-only | tx-only | tx-rx | disable}
 set lldp-profile <profile name>
 end
 end
 end
```

For example:

```
config switch-controller managed-switch
 edit S524DF4K15000024
 config ports
 edit port2
 set lldp-status tx-rx
 set lldp-profile default
 end
 end
 end
```

## Configuring IGMP settings

IGMP snooping allows the FortiSwitch to passively listen to the Internet Group Management Protocol (IGMP) network traffic between hosts and routers. The switch uses this information to determine which ports are interested in receiving each multicast feed. FortiSwitch can reduce unnecessary multicast traffic on the LAN by pruning multicast traffic from links that do not contain a multicast listener.

```
config switch-controller managed-switch
 edit <switch-id>
 config ports
 edit <port name>
 set igmp-snooping {enable | disable}
 set igmps-flood-reports {enable | disable}
 end
 end
 end
```

For example:

```
config switch-controller managed-switch
 edit S524DF4K15000024
 config ports
 edit port3
 set igmp-snooping enable
 set igmps-flood-reports enable
 end
 end
 end
```

## FortiSwitch port security policy

The features listed here are valuable in endpoint authorization and access-control within a retail/enterprise LAN environment. In a FortiLink setup, you can configure these capabilities from the FortiGate while endpoints are connected to switch ports.

**NOTE:** In FortiLink mode, you must manually create a firewall policy to allow RADIUS traffic for 802.1x authentication from the FortiSwitch (for example, from the FortiLink interface) to the RADIUS server through the FortiGate.

End devices fall into two supported categories: one that supports 802.1X client and one that does not.

Before the Managed Release 5.6.0, only the following configuration was supported per VLAN:

- 802.1X

With Managed Release 5.6.0, additional port security features are available:

- Move 802.1X control from VLAN to port
  - Previously, only one VLAN could be assigned to one port. With both tagged and untagged VLANs allowed in 5.4.x, this is no longer suitable and will be migrated to the switch port.
  - Automatic configuration migration is supported.
- Support for client-less devices using mac-auth-bypass (MAB)
  - For devices that are incapable of supporting EAPoL/EAP, FortiSwitch will conduct the authentication on behalf of the device. A maximum of three concurrent MAB devices per port can exist.
- Multiple secured endpoints on single port
  - Enforcement is per MAC address
- Dynamic VLAN assignment
  - RADIUS-assigned VLANs
- Guest VLAN configuration
  - With authentication timeout
- RADIUS configuration
  - Set secret keys for primary and secondary servers.
- User configuration
  - Use a RADIUS server to authenticate users.
- Additional timers and modes
  - Re-authentication period
  - Maximum re-authentication attempts
  - Link down to un-authenticate

**NOTE:** In the following commands, "\*" indicates the default setting.

## Configure the 802.1X settings for a virtual domain

To configure the 802.1X security policy for a virtual domain, use the following commands:

```
config switch-controller 802-1X-settings
 set reauth-period < int >
 set max-reauth-attempt < int >
 set link-down-auth < *set-unauth | no-action >
end
```

| Option                              | Description                                                                                                                                                                                                                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>set link-down-auth</code>     | If a link is down, this command determines the authentication state. Choosing <code>set-auth</code> sets the interface to unauthenticated when a link is down, and reauthentication is needed. Choosing <code>no-auth</code> means that the interface does not need to be reauthenticated when a link is down. |
| <code>set reauth-period</code>      | This command sets how often reauthentication is needed. The range is 1-1440 minutes. The default is 60 minutes. Setting the value to 0 minutes disables reauthentication.                                                                                                                                      |
| <code>set max-reauth-attempt</code> | This command sets the maximum number of reauthentication attempts. The range is 1-15. the default is 3. Setting the value to 0 disables reauthentication.                                                                                                                                                      |

## Override the virtual domain settings

You can override the virtual domain settings for the 802.1X security policy.

### Using the FortiGate GUI

To override the 802.1X settings for a virtual domain:

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click on a FortiSwitch faceplate and click **Edit**.
3. In the Edit Managed FortiSwitch page, move the **Override 802-1X settings** slider to the right.
4. In the Reauthentication Interval field, enter the number of minutes before reauthentication is required. The maximum interval is 1,440 minutes. Setting the value to 0 minutes disables reauthentication.
5. In the Max Reauthentication Attempts field, enter the maximum times that reauthentication is attempted. The maximum number of attempts is 15. Setting the value to 0 disables reauthentication.
6. Select **Deauthenticate** or **None** for the link down action. Selecting **Deauthenticate** sets the interface to unauthenticated when a link is down, and reauthentication is needed. Selecting **None** means that the interface does not need to be reauthenticated when a link is down.
7. Click **OK**.

### Using the FortiGate CLI

To override the 802.1X settings for a virtual domain, use the following commands:

```
config switch-controller managed-switch
 edit < switch >
 config 802-1X-settings
 set local-override [enable | *disable]
 set reauth-period < int > // visible if override enabled
 set max-reauth-attempt < int > // visible if override enabled
 set link-down-auth < *set-unauth | no-action > // visible if override enabled
 end
 next
end
```

For a description of the options, see [Configure the 802.1X settings for a virtual domain](#).

## Define an 802.1X security policy

You can define multiple 802.1X security policies.

### Using the FortiGate GUI

To create an 802.1X security policy:

1. Go to **WiFi & Switch Controller > FortiSwitch Security Policies**.
2. Click **Create New**.
3. Enter a name for the new FortiSwitch security policy.
4. For the security mode, select **Port-based** or **MAC-based**.
5. Click **+** to select which user groups will have access.
6. Enable or disable guest VLANs on this interface to allow restricted access for some users.
7. Enter the number of seconds for authentication delay for guest VLANs. The range is 60-900 seconds.
8. Enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN.
9. Enable or disable MAC authentication bypass (MAB) on this interface.
10. Enable or disable EAP pass-through mode on this interface.
11. Enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.
12. Click **OK**.

### Using the FortiGate CLI

To create an 802.1X security policy, use the following commands:

```
config switch-controller security-policy 802-1X
 edit "<policy.name>"
 set security-mode {802.1X | 802.1X-mac-based}
 set user-group <*group_name | Guest-group | SSO_Guest_Users>
 set mac-auth-bypass [enable | *disable]
 set eap-passthru [enable | disable]
 set guest-vlan [enable | *disable]
 set guest-vlan-id "guest-VLAN-name"
 set guest-auth-delay <integer>
 set auth-fail-vlan [enable | *disable]
 set auth-fail-vlan-id "auth-fail-VLAN-name"
 set radius-timeout-overwrite [enable | *disable]
 set policy-type 802.1X
 end
end
```

| Option            | Description                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------|
| set security-mode | You can restrict access with 802.1X port-based authentication or with 802.1X MAC-based authentication. |
| set user-group    | You can set a specific group name, Guest-group, or SSO_Guest_Users to have access.                     |

| Option                                                   | Description                                                                                                                                  |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>set mac-auth-bypass</code>                         | You can enable or disable MAB on this interface.                                                                                             |
| <code>set eap-passthrough</code>                         | You can enable or disable EAP pass-through mode on this interface.                                                                           |
| <code>set guest-vlan</code>                              | You can enable or disable guest VLANs on this interface to allow restricted access for some users.                                           |
| <code>set guest-vlan-id "guest-VLAN-name"</code>         | You can specify the name of the guest VLAN.                                                                                                  |
| <code>set guest-auth-delay</code>                        | You can set the authentication delay for guest VLANs on this interface. The range is 60-900 seconds.                                         |
| <code>set auth-fail-vlan</code>                          | You can enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN. |
| <code>set auth-fail-vlan-id "auth-fail-VLAN-name"</code> | You can specify the name of the authentication fail VLAN                                                                                     |
| <code>set radius-timeout-overwrite</code>                | You can enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.                                |
| <code>set policy-type 802.1X</code>                      | You can set the policy type to the 802.1X security policy.                                                                                   |

## Apply an 802.1X security policy to a FortiSwitch port

You can apply a different 802.1X security policy to each FortiSwitch port.

### Using the FortiGate GUI

To apply an 802.1X security policy to a managed FortiSwitch port:

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**.
2. Click the **+** next to a FortiSwitch.
3. In the Security Policy column for a port, click **+** to select a security policy.
4. Click **OK** to apply the security policy to that port.

### Using the FortiGate CLI

To apply an 802.1X security policy to a managed FortiSwitch port, use the following commands:

```
config switch-controller managed-switch
 edit <managed-switch>
 config ports
 edit <port>
 set port-security-policy <802.1X-policy>
 next
 end
 next
end
```

## Additional capabilities

This chapter covers the following topics:

- [Execute custom FortiSwitch commands on page 2401](#)
- [Firmware upgrade management and compatible version information on page 2402](#)
- [FortiSwitch log export on page 2402](#)
- [FortiSwitch per-port device visibility on page 2403](#)
- [FortiGate CLI support for FortiSwitch features \(on non-FortiLink ports\) on page 2403](#)

### Execute custom FortiSwitch commands

From the FortiGate, you can execute FortiSwitch commands on the managed FortiSwitch.

This feature adds a simple scripting mechanism for users to execute generic commands on the switch.

**NOTE:** FortiOS 5.6.0 introduces additional capabilities related to the managed FortiSwitch.

#### Create a command

Use the following syntax to create a command file:

```
config switch-controller custom-command
 edit <cmd-name>
 set command " <FortiSwitch commands>"
```

Next, create a command file to set the STP max-age parameter:

```
config switch-controller custom-command
 edit "stp-age-10"
 set command "config switch stp setting
 set max-age 10
 end
 "
next
end
```

#### Execute a command

After you have created a command file, use the following command on the FortiGate to execute the command file on the target switch:

```
exec switch-controller custom-command <cmd-name> <target-switch>
```

The following example runs the **stp-age-10** command on the specified target FortiSwitch:

```
exec switch-controller custom-command stp-age-10 S124DP3X15000118
```

## Firmware upgrade management and compatible version information

You can view the current firmware version of a FortiSwitch and upgrade the FortiSwitch to a new firmware version. FortiGate will suggest an upgrade when a new version is available in FortiGuard.

### Using the FortiGate Web interface

To view the FortiSwitch firmware version:

1. Go to **WiFi & Switch Controller>Managed FortiSwitch**.
2. In the main panel, select the FortiSwitch and click **Edit**.
3. In the **Edit Managed FortiSwitch** panel, the **Firmware** section displays the current build on the FortiSwitch.

To update the FortiSwitch firmware version:

1. Click **Update** to open the **Update Firmware** panel.
2. Click **Select File**. In the file chooser, click the image file and click **Open**.
3. Click **Upload and Reboot** to install the new image and reboot the FortiSwitch.

### Using the CLI

Use the following command to display the latest version:

```
diagnose fdsm fortisw-latest-ver <model>
```

Use the following command to download the image:

```
diagnose fdsm fortisw-download <image id>
```

The following example shows how to download the latest image for FS224D:

```
FG100D3G15801204 (global) # diagnose fdsm fortisw-latest-ver FS224D
FS224D - 3.4.2 b192 03004000FIMG0900904002FG100D3G15801204 (global) #

diagnose fdsm fortisw-download 03004000FIMG0900904002

Download image-03004000FIMG0900904002:
#####
Result=Success
```

## FortiSwitch log export

You can enable and disable the managed FortiSwitches to export their syslogs to the FortiGate. The setting is global, and the default setting is enabled. Starting in FortiOS 5.6.3, more details are included in the exported FortiSwitch logs.

To allow a level of filtering, FortiGate sets the user field to "fortiswitch-syslog" for each entry.

The following is the CLI command syntax:

```
config switch-controller switch-log
 set status (*enable | disable)
 set severity [emergency | alert | critical | error | warning | notification |
 *information | debug]
```

```
end
```

You can override the global log settings for a FortiSwitch, using the following commands:

```
config switch-controller managed-switch
edit <switch-id>
config switch-log
set local-override enable
```

At this point, you can configure the log settings that apply to this specific switch.

## FortiSwitch per-port device visibility

In the FortiGate GUI, **User & Device > Device List** displays a list of devices attached to the FortiSwitch ports. For each device, the table displays the IP address of the device and the interface (FortiSwitch name and port).

From the CLI, the following command displays information about the host devices:

```
diagnose switch-controller dump mac-hosts_switch-ports
```

## FortiGate CLI support for FortiSwitch features (on non-FortiLink ports)

You can configure the following FortiSwitch features from the FortiGate CLI.

### Configuring a link aggregation group (LAG)

You can configure a link aggregation group (LAG) for non-FortiLink ports on a FortiSwitch. You cannot configure ports from different FortiSwitches in one LAG.

```
config switch-controller managed-switch
edit <switch-id>
config ports
it <trunk name>
set type trunk
set mode < static | lacp > Link Aggregation mode
set bundle (enable | disable)
set min-bundle <int>
set max-bundle <int>
set members < port1 port2 ...>
next
end
end
end
```

### Configuring an MCLAG with managed FortiSwitches

A multichassis LAG (MCLAG) provides node-level redundancy by grouping two FortiSwitch models together so that they appear as a single switch on the network. If either switch fails, the MCLAG continues to function without any interruption, increasing network resiliency and eliminating the delays associated with the Spanning Tree Protocol (STP). For the network topology, see [Dual-homed servers connected to FortiLink tier-1 FortiSwitches using an MCLAG](#) and [Standalone FortiGate with dual-homed FortiSwitch access](#).

## Notes

- Both peer switches should be of the same hardware model and same software version. Mismatched configurations might work but are unsupported.
- There is a maximum of two FortiSwitch models per MLAG.
- The routing feature is not available within an MLAG.
- For static MAC addresses within an MLAG, if one FortiSwitch learns the MAC address, the second FortiSwitch will automatically learn the MAC address.

### To configure an MLAG with managed FortiSwitches:

1. For each MLAG peer switch, log into the FortiSwitch to create a LAG:

```
config switch trunk
 edit "LAG-member"
 set mode lacp-active
 set mclag-icl enable
 set members "<port>" "<port>"
 next
```

2. Enable the MLAG on each managed FortiSwitch:

```
config switch-controller managed-switch
 edit "<switch-id>"
 config ports
 edit "<trunk name>"
 set type trunk
 set mode {static | lacp-passive | lacp-active}
 set bundle {enable | disable}
 set members "<port>,<port>"
 set mclag {enable | disable}
 next
 end
 next
```

3. Log into each managed FortiSwitch to check the MLAG configuration:

```
diagnose switch mclag
```

After the FortiSwitches are configured as MLAG peer switches, any port that supports advanced features on the FortiSwitch can become a LAG port. When `mclag` is enabled and the LAG port names match, an MLAG peer set is automatically formed. The member ports for each FortiSwitch in the MLAG do not need to be identical to the member ports on the peer FortiSwitch.

## Configuring storm control

Storm control uses the data rate (packets/sec, default 500) of the link to measure traffic activity, preventing traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on a port.

When the data rate exceeds the configured threshold, storm control drops excess traffic. You can configure the types of traffic to drop: broadcast, unknown unicast, or multicast.

The storm control settings are global to all of the non-FortiLink ports on the managed switches. Use the following CLI commands to configure storm control:

```
config switch-controller storm-control
 set rate <rate>
 set unknown-unicast (enable | disable)
 set unknown-multicast (enable | disable)
 set broadcast (enable | disable)
end
```

You can override the global storm control settings for a FortiSwitch using the following commands:

```
config switch-controller managed-switch
 edit <switch-id>
 config storm-control
 set local-override enable
```

At this point, you can configure the storm control settings that apply to this specific switch.

## Displaying port statistics

Port statistics will be accessed using the following FortiSwitch CLI command:

```
FG100D3G15804763 # diagnose switch-controller dump port-stats
S124DP3X16000413 port8
S124DP3X16000413 0 :
{
 "port8":{
 "tx-bytes":823526672,
 "tx-packets":1402390,
 "tx-ucast":49047,
 "tx-mcast":804545,
 "tx-bcast":548798,
 "tx-errors":0,
 "tx-drops":3,
 "tx-oversize":0,
 "rx-bytes":13941793,
 "rx-packets":160303,
 "rx-ucast":148652,
 "rx-mcast":7509,
 "rx-bcast":4142,
 "rx-errors":0,
 "rx-drops":720,
 "rx-oversize":0,
 "undersize":0,
 "fragments":0,
 "jabbers":0,
 "collisions":0,
 "crc-alignments":0,
 "l3packets":0
 }
}
```

## Configuring QoS with managed FortiSwitches

Quality of Service (QoS) provides the ability to set particular priorities for different applications, users, or data flows.

**NOTE:** FortiGate does not support QoS for hard or soft switch ports.

FortiSwitch supports the following QoS configuration capabilities:

- Mapping the IEEE 802.1p and Layer 3 QoS values (Differentiated Services and IP Precedence) to an outbound QoS queue number.
- Providing eight egress queues on each port.
- Policing the maximum data rate of egress traffic on the interface.

**To configure the QoS for managed FortiSwitches:**

**1. Configure a Dot1p map.**

A Dot1p map defines a mapping between IEEE 802.1p class of service (CoS) values (from incoming packets on a trusted interface) and the egress queue values. Values that are not explicitly included in the map will follow the default mapping, which maps each priority (0-7) to queue 0. If an incoming packet contains no CoS value, the switch assigns a CoS value of zero.

**NOTE:** Do not enable trust for both Dot1p and DSCP at the same time on the same interface. If you do want to trust both Dot1p and IP-DSCP, the FortiSwitch uses the latter value (DSCP) to determine the queue. The switch will use the Dot1p value and mapping only if the packet contains no DSCP value.

```
config switch-controller qos dot1p-map
 edit <Dot1p map name>
 set description <text>
 set priority-0 <queue number>
 set priority-1 <queue number>
 set priority-2 <queue number>
 set priority-3 <queue number>
 set priority-4 <queue number>
 set priority-5 <queue number>
 set priority-6 <queue number>
 set priority-7 <queue number>
 next
end
```

**2. Configure a DSCP map.**

A DSCP map defines a mapping between IP precedence or DSCP values and the egress queue values. For IP precedence, you have the following choices:

- network-control—Network control
- internetwork-control—Internetwork control
- critic-ecp—Critic and emergency call processing (ECP)
- flashoverride—Flash override
- flash—Flash
- immediate—Immediate
- priority—Priority
- routine—Routine

```
config switch-controller qos ip-dscp-map
 edit <DSCP map name>
 set description <text>
 configure map <map_name>
```

```

edit <entry name>
 set cos-queue <COS queue number>
 set diffserv {CS0 | CS1 | AF11 | AF12 | AF13 | CS2 | AF21 | AF22 | AF23
 | CS3 | AF31 | AF32 | AF33 | CS4 | AF41 | AF42 | AF43 | CS5 | EF |
 CS6 | CS7}
 set ip-precedence {network-control | internetwork-control | critic-ecp
 | flashoverride | flash | immediate | priority | routine}
 set value <DSCP raw value>
next
end
end

```

### 3. Configure the egress QoS policy.

In a QoS policy, you set the scheduling mode for the policy and configure one or more CoS queues. Each egress port supports eight queues, and three scheduling modes are available:

- With strict scheduling, the queues are served in descending order (of queue number), so higher number queues receive higher priority.
- In simple round-robin mode, the scheduler visits each backlogged queue, servicing a single packet from each queue before moving on to the next one.
- In weighted round-robin mode, each of the eight egress queues is assigned a weight value ranging from 0 to 63.

```

config switch-controller qos queue-policy
edit <QoS egress policy name>
 set schedule {strict | round-robin | weighted}
 config cos-queue
 edit [queue-<number>]
 set description <text>
 set min-rate <rate in kbps>
 set max-rate <rate in kbps>
 set drop-policy {taildrop | random-early-detection}
 set weight <weight value>
 next
end
next
end

```

### 4. Configure the overall policy that will be applied to the switch ports.

```

config switch-controller qos qos-policy
edit <QoS egress policy name>
 set default-cos <default CoS value 0-7>
 set trust-dot1p-map <Dot1p map name>
 set trust-ip-dscp-map <DSCP map name>
 set queue-policy <queue policy name>
next
end

```

### 5. Configure each switch port.

```

config switch-controller managed-switch
edit <switch-id>
 config ports
 edit <port>

```

```
 set qos-policy <CoS policy>
 next
 end
 next
end
```

## Troubleshooting

### Troubleshooting FortiLink issues

If the FortiGate does not establish the FortiLink connection with the FortiSwitch, perform the following troubleshooting checks.

#### Check the FortiGate configuration

**To use the FortiGate GUI to check the FortiLink interface configuration:**

1. In **Network > Interfaces**, double-click the interface used for FortiLink.
2. Ensure that **Dedicated to FortiSwitch** is set for this interface.

**To use the FortiGate CLI to verify that you have configured the DHCP and NTP settings correctly:**

1. Verify that the NTP server is enabled and that the FortiLink interface has been added to the list:

```
show system ntp
```

2. Ensure that the DHCP server on the Fortilink interface is configured correctly:

```
show system dhcp
```

#### Check the FortiSwitch configuration

**To use FortiSwitch CLI commands to check the FortiSwitch configuration:**

1. Verify that the switch system time matches the time on the FortiGate:

```
get system status
```

2. Verify that FortiGate has sent an IP address to the FortiSwitch (anticipate an IP address in the range 169.254.x.x):

```
get system interfaces
```

3. Verify that you can ping the FortiGate IP address:

```
exec ping x.x.x.x
```

**To use FortiGate CLI commands to check the FortiSwitch configuration:**

1. Verify that the connections from the FortiGate to the FortiSwitches are up:

```
exec switch-controller get-conn-status
```

2. Verify that ports for a specific FortiSwitch stack are connected to the correct locations:

```
exec switch-controller get-physical-conn <FortiSwitch-Stack-ID>
```

3. Verify that all the ports for a specific FortiSwitch are up:

```
exec switch-controller get-conn-status <FortiSwitch-device-ID>
```

# Chapter 21 - Networking

## Networking

This guide explains how to configure your network. It contains the following sections:

| Chapter title            | Description                                                                                                                                                                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interfaces               | <ul style="list-style-type: none"><li>Explains the concepts of options for setting up interfaces and groupings of sub-networks that can scale to a company's growing requirements</li></ul>                                                                            |
| DNS                      | <ul style="list-style-type: none"><li>How to set DNS requirements for your network</li><li>How to set FortiGate as a local DNS server</li></ul>                                                                                                                        |

## What's new in Networking

This section contains a list of new features and enhancements for Networking.

## FortiOS version 5.6.4

There are no new features for Networking in FortiOS version 5.6.4.

## FortiOS version 5.6.3

FortiOS version 5.6.3 includes the following new features and enhancements for Networking.

### VXLAN loopback binding support

A Virtual Extensible LAN (VXLAN) unicast device can bind to a loopback interface as its underlying interface.

For more information, see [VXLAN loopback binding on page 2433](#).

### New option to configure DHCP renew time

You can now set a minimum DHCP renew time.

For more information, see [Configuring the DHCP renew time on page 2424](#).

### Fixed inability to delete multicast interfaces in the GUI

An issue where you could not delete interfaces in the GUI under **Network > Multicast > Multicast Routing** has been fixed.

### New CLI commands for showing and adding IPv6 addresses

In previous releases, you could only view client IPv6 DHCP addresses in the CLI by using `diagnose ipv6 address list`. This release introduces the ability to also view these addresses by entering `get` in the `interface` (under `config system interface`).

Similarly, in previous releases, you could only view static IPv6 addresses under `diagnose ipv6 address list` and by entering `get` under the `interface`. This release introduces the ability to also view them by entering `fnsysctl/sysctl ifconfig interface_id`.

### Static route GUI updates

The GUI pages for creating or editing static routes (under **Network > Static Routes**) have been updated.

When you create or edit a static route, you must specify the gateway first and then select the device interface. The FortiGate GUI will try to populate the **Interface** field based on the value in the **Gateway** field. If you specify a gateway that is not in the same subnet as the selected interface, a warning message will appear.

Also, the **Device** field has been renamed to the **Interface** field.

### DHCP relay agent option configuration

FortiGate now supports the ability to enable or disable the DHCP relay agent option.

For more information, see [Configuring the DHCP relay agent option on page 2422](#).

## FortiOS version 5.6.2

There are no new features for Networking in FortiOS version 5.6.2.

## FortiOS version 5.6.1

FortiOS version 5.6.1 includes the following new features and enhancements for Networking.

### Recursive DNS server option

FortiGate now supports the following RFC 6106 IPv6 Router Advertisement options:

- Sending DNS search list option to downstream clients with Router Advertisements that use a static prefix
- Sending Recursive DNS server option to downstream clients with Router Advertisements that use a static prefix

For more information, see [Configuring IPv6 Router Advertisement options for DNS configuration on page 2470](#).

### Routing Monitor support for policy routes

You can now monitor policy routes using the FortiGate GUI. The **Routing Monitor** page now includes a **Policy** option that lists the active policy routes on the FortiGate and provides information about them.

For more information, see [Viewing the routing table on page 2475](#).

### Control how routing changes affect active sessions

You can now control how active sessions are affected when dynamic routing changes occur that affect the routes the active sessions are using. You can configure whether FortiGate maintains the original routing for the sessions that are using the affected routes, or applies the routing table changes to the active sessions.

For more information, see [Controlling how routing changes affect active sessions on page 2517](#).

## FortiOS version 5.6

FortiOS version 5.6 includes the following new features and enhancements for Networking.

### New command to view transceiver information

You can now use a command to display information about transceivers installed in FortiGate SFP/SFP+ interfaces. You can use this command on most FortiGate models that have SFP/SFP+ interfaces.

For more information, see [Displaying information about the status of transceivers on page 2436](#).

### BGP local-AS support

FortiGate now supports BGP local-AS.

For more information, see [BGP local-AS support on page 2611](#).

### Interface setting removed from SNMP community configuration page

The Interface column has been removed from the **New SNMP Community** configuration page (**System > SNMP > SNMP v1/v2c > Create New**) in the FortiGate GUI.

### Remove RPF checks from the state evaluation process

You can now remove RPF (reverse path forwarding) state checks without needing to enable asymmetric routing, using the new `set src-check disable` CLI command.

For more information, see [Removing RPF checks from the state evaluation process on page 2486](#).

## BGP enhancements

FortiGate now supports the following BGP enhancements:

- Option to stop BGP graceful restart process on timer only
- Option to bring down BGP neighbor upon link down
- Option to keep routes for a period after the BGP neighbor is down

For more information, see [Configuring BGP graceful restart process on timer on page 2610](#), [Configuring option to bring down BGP neighbor when the link is down on page 2611](#), and [Configuring option to keep routes for a period after the BGP neighbor is down on page 2611](#).

## FQDN support for static routes

You can now configure FQDN firewall addresses as destination addresses in a static route.

For more information, see [Configuring FQDNs as a destination address in static routes on page 2474](#).

## Priority for blackhole routes

You can now add a priority to a blackhole route to change its position relative to kernel routes in the routing table.

For more information, see [Adding a blackhole route with a priority on page 2484](#).

## DDNS refresh interval

You can now configure FortiGate to refresh DDNS IP addresses by periodically checking the configured DDNS server.

For more information, see [Configuring FortiGate to refresh DDNS IP addresses on page 2467](#).

## GUI support for configuring IPv6 blackhole routes

You can now configure IPv6 blackhole routes in the FortiGate GUI.

For more information, see [Configuring IPv6 blackhole routes on page 2483](#).

## Support for SSL VPN and WAN link load balancing

You can now set virtual WAN link interfaces as destination interfaces in firewall policies for WAN link load balancing, when SSL VPN is the source interface.

For more information, see [SSL VPN and WAN link load balancing on page 2443](#).

## DDNS support for No-IP

FortiGate now supports No-IP as a DDNS server.

## IPv6 Router Advertisement options for DNS configuration

FortiGate now supports the following RFC 6106 IPv6 Router Advertisement options:

- Obtaining DNS search list options from upstream DHCPv6 servers
- Sending the DNS search list through Router Advertisement
- Sending the DNS search list through the FortiGate DHCP server

For more information, see [Configuring IPv6 Router Advertisement options for DNS configuration on page 2470](#).

## **SD-WAN replaces WAN LLB in FortiGate GUI**

The term SD-WAN has replaced the term WAN LLB throughout the FortiGate GUI.

## Interfaces

Interfaces, both physical and virtual, allow traffic to flow between internal networks and the Internet, and between internal networks. FortiGate has a number of options for setting up interfaces and groupings of subnetworks that can scale to your organization's growing requirements.

### Administrative access

To help prevent FortiGate interfaces, especially the public-facing ports, from being accessed by users who you do not want accessing them, you can configure protocols that an administrator must use to access FortiGate, including:

- HTTPS
- PING
- FortiManager Access (FMG-Access)
- CAPWAP
- SSH
- SNMP
- FTM
- RADIUS Accounting
- FortiTelemetry

As a best practice, you should configure administrative access when you are setting the IP address for the port.

The following example adds an IPv4 address 172.20.120.100 to the WAN1 interface, and administrative access to HTTPS and SSH.

#### Add an IP address to the WAN1 interface - web-based manager

1. Go to **Network > Interface**.
2. Select the WAN1 interface row and select **Edit**.
3. Select the **Addressing Mode** of **Manual**.
4. Enter the IP address for the port of 172.20.120.100/24.
5. For **Administrative Access**, select **HTTPS** and **SSH**.
6. Select **OK**.

#### Add an IP address to the WAN1 interface - CLI

```
config system interface
 edit wan1
 set ip 172.20.120.100/24
 set allowaccess https ssh
 end
```

When you add or remove a protocol, you must type the entire list of protocols again. For example, if you have an access list of HTTPS and SSH and you want to add PING, you must use the following CLI command:

```
set allowaccess https ssh ping
```

If you use `set allowsaccess ping`, only ping is set and HTTPS and SSH are removed.

---

## Aggregate interfaces

Link aggregation (IEEE 802.3ad) allows you to bind two or more physical interfaces together to form an aggregated link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is automatically transferred to the remaining interfaces with the only noticeable effect being reduced bandwidth.

This is similar to redundant interfaces, with the major difference being that a redundant interface group uses only one link at a time, while an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

Some FortiGate models support the IEEE standard 802.3ad for link aggregation.

An interface can be an aggregate interface if it meets the following criteria:

- It is a physical interface, not a VLAN interface or subinterface.
- It is not already part of an aggregate or redundant interface.
- It is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It is not referenced in any security policy, VIP, IP pool, or multicast policy.
- It is not an HA heartbeat interface.
- It is not one of the backplane interfaces of the FortiGate 5000 series.

Some FortiGate models do not support aggregate interfaces. In this case, the aggregate option is not available in the FortiGate GUI or CLI. Also, you cannot create aggregate interfaces from interfaces in a switch port.

To see if a port is being used or has other dependencies, use the following CLI command:

```
diagnose sys checkused system.interface.name <interface_name>
```

When an interface is included in an aggregate interface, it is not listed in the **Network > Interface** page in the FortiGate GUI. Interfaces still appear in the CLI, but if you configure those interfaces, it will not take effect. You cannot configure the interface individually and it is not available to include in security policies, VIPs, IP pools, or routing.

To avoid unintentional network issues when you configure Link Aggregation Control Protocol (LACP), disconnect the interfaces that you want to add to the aggregate interface. After you finish configuring LACP, reconnect the interfaces.

The following example creates an aggregate interface on a FortiGate 3810A, using ports 4 to 6, with an internal IP address of 10.13.101.100, and administrative access to HTTPS and SSH.

### Create an aggregate interface - web-based manager

1. Go to **Network > Interface** and select **Create New**, then **Interface**.
2. Enter the Name as `Aggregate`.
3. For the **Type**, select **802.3ad Aggregate**.  
If this option does not appear, your FortiGate unit does not support aggregate interfaces.
4. In the **Physical Interface Members**, click to add interfaces. Select port 4, 5, and 6.
5. Select the **Addressing Mode** of **Manual**.
6. Enter the IP address for the port of 10.13.101.100/24.
7. For **Administrative Access**, select HTTPS and SSH.
8. Select **OK**.

### Create aggregate interface - CLI

```
config system interface
 edit Aggregate
 set type aggregate
 set member port4 port5 port6
 set vdom root
 set ip 172.20.120.100/24
 set allowaccess https ssh
 end
```

### Sending GARP on aggregate MAC changes

FortiGate sends out GARP (Gratuitous Address Resolution Protocol) announcements if the MAC address of a link aggregated interface changes to a new IP pool address due to a link failure or change in ports. This is needed when you use networking devices, such as some switches that do not perform this function when they receive LACP (Link Aggregation Control Protocol) information about changes in the MAC information.

### DHCP addressing mode on an interface

If you configure an interface to use DHCP, FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

---

DHCP IPv6 is similar to DHCP IPv4, except:

- No default gateway option is defined because a host learns the gateway using router advertisement messages.
- There are no WINS servers because it is obsolete.

For more information about DHCP IPv6, see [RFC 3315](#).

---

You can configure DHCP for an interface in **Network > Interfaces** in the FortiGate GUI. Select the interface from the list, and select **DHCP** in the **Addressing mode**. The following table describes the DHCP status information when DHCP is configured for an interface.

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b>                               | <p>Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Select <b>Status</b> to refresh the addressing mode status message.</p> <p>Status can be one of the following values:</p> <ul style="list-style-type: none"> <li>• <b>initializing</b>: no activity</li> <li>• <b>connecting</b>: interface attempts to connect to the DHCP server</li> <li>• <b>connected</b>: interface retrieves an IP address, netmask, and other settings from the DHCP server</li> <li>• <b>failed</b>: interface was unable to retrieve an IP address and other settings from the DHCP server</li> </ul> |
| <b>Obtained IP/Netmask</b>                  | The IP address and netmask leased from the DHCP server. This is only displayed if the <b>Status</b> is <b>connected</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Renew</b>                                | Select this to renew the DHCP license for this interface. This is only displayed if the <b>Status</b> is <b>connected</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Expiry Date</b>                          | The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the <b>Status</b> is <b>connected</b> .                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default Gateway</b>                      | The IP address of the gateway defined by the DHCP server. This is displayed only if the <b>Status</b> is <b>connected</b> , and if <b>Receive default gateway from server</b> is selected.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Distance</b>                             | Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255, and specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.                                                                                                                                                                                                                                                                                                                    |
| <b>Retrieve default gateway from server</b> | Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Override internal DNS</b>                | <p>Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>                                                                                                                                                                                                                                                                                                                                                                                                               |

## DHCP servers and relays

A DHCP server provides an address, from a defined address range, to a client on the network that requests it.

An interface cannot provide both a server and a relay for connections of the same type (regular or IPsec). However, you can configure a regular DHCP server on an interface only if the interface is a physical interface with a static IP address. You can configure an IPsec DHCP server on an interface that has either a static or a dynamic IP address.

You can configure one or more DHCP servers on any FortiGate interface. A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

You can configure a FortiGate interface as a DHCP relay. The interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

DHCP server options are not available in transparent mode.

## Configuring DHCP servers

To add a DHCP server, go to **Network > Interfaces**. Edit the interface, and select **DHCP** in the addressing mode.

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address Range</b>   | <p>By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address.</p> <p>For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254.</p> <p>Select the range and select <b>Edit</b> to adjust the range or select <b>Create New</b> to add a different range.</p> |
| <b>Netmask</b>         | Enter the netmask of the addresses that the DHCP server assigns.                                                                                                                                                                                                                                                                                                                                    |
| <b>Default Gateway</b> | Select this to use either <b>Same as Interface IP</b> or select <b>Specify</b> and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.                                                                                                                                                                                                                        |
| <b>DNS Server</b>      | Select this to use <b>Same as system DNS</b> , <b>Same as Interface IP</b> or select <b>Specify</b> and enter the IP address of the DNS server.                                                                                                                                                                                                                                                     |
| <b>Mode</b>            | Select the type of DHCP server FortiGate will be. By default, it is a <b>Server</b> . Select <b>Relay</b> if needed. When <b>Relay</b> is selected, the above configuration is replaced by a field to enter the <b>DHCP Server IP</b> address.                                                                                                                                                      |
| <b>DHCP Server IP</b>  | This appears only when <b>Mode</b> is <b>Relay</b> . Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.                                                                                                                                                                                                                                                      |

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type                         | Select this to use the DHCP in <b>Regular</b> or <b>IPsec</b> mode.                                                                                                                                                                                                                                                                                                                                                     |
| Additional DHCP Options      | Use this to create new DHCP options.                                                                                                                                                                                                                                                                                                                                                                                    |
| MAC Address + Access Control | <p>Select this to match an IP address from the DHCP server to a specific client or device using its MAC address.</p> <p>In a typical situation, an IP address is assigned ad hoc to a client, and that assignment times out after a specific time of inactivity from the client, known as the lease time. To ensure a client or device always has the same IP address (there is no lease time), use IP reservation.</p> |
| Add from DHCP Client List    | If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.                                                                                                                                                                                                                                                                       |

## Configuring the DHCP relay agent option

You can configure the DHCP relay agent option (option 82 in RFC 3046). You can enable or disable whether the DHCP relay agent option is added. This option is disabled, by default.

To configure the DHCP relay agent option, use the following CLI commands:

```
config system interface
```

```
edit <name>
 set dhcp-relay-agent-option [enable | disable]
next
```

For more information about the DHCP relay option, see [RFC 3046](#) (DHCP Relay Agent Information Option).

## Configuring DHCP with IPv6

You can use DHCP with IPv6, using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Feature Visibility** and enable **IPv6** under **Basic Features**. Use the following CLI command:

```
config system dhcp6 server
```

### DHCPv6 prefix delegation

Prefix delegation is supported for DHCP for IPv6 addressing. It is not practical to manually provision networks on a large scale in IPv6 networking. The DHCPv6 prefix delegation feature is used to assign a network address prefix, and automate the configuration and provisioning of the public routable addresses for the network.

You can enable the prefix delegation, using the following CLI commands:

```
config system interface
edit "wan1"
 config ipv6
 set ip6-mode dhcp
 set ip6-allowaccess ping
 set dhcp6-prefix-delegation enable
 end
end
```

### DHCPv6 prefix hint

This feature is used to "hint" to upstream DHCPv6 servers a desired prefix length for their subnet to be assigned in response to its request.

There is a possibility of duplicate prefixes being sent by ISP when using a /64 bit subnet because the first 64 bits of the address are derived from the MAC address of the interface. This could cause an issue if the system administrator wishes to divide the host networks into 2 /64 bit subnets.

By receiving a /60 bit (for example) network address, the administrator can then divide the internal host works without the danger of creating duplicate subnets.

Also included in the new feature, are preferred times for the life and valid life of the DHCP lease.

DHCPv6 hint for the prefix length:

```
set dhcp6-prefix-hint <DHCPv6 prefix that will be used as a hint to the upstream DHCPv6 server>
```

DHCPv6 hint for the preferred life time:

```
set dhcp6-prefix-hint-plt <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time
```

DHCPv6 hint for the valid life time:

```
set dhcp6-prefix-hint-vlt <integer> 1 ~ 4294967295 seconds or "0" for unlimited lease time
```

## Service

On low-end FortiGate units, a DHCP server is configured on the internal interface, by default, with the following values:

| Field           | Value                          |
|-----------------|--------------------------------|
| Address Range   | 192.168.1.110 to 192.168.1.210 |
| Netmask         | 255.255.255.0                  |
| Default Gateway | 192.168.1.99                   |
| Lease Time      | 7 days                         |
| DNS Server 1    | 192.168.1.99                   |

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

Alternatively, after the FortiGate unit assigns an address, you can go to **Monitor > DHCP Monitor** and locate the specific user. Right-click and select **Create/Edit IP Reservation**.

## Configuring the lease time

The lease time determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the lease time, use the following CLI commands:

```
config system dhcp server
 edit <server_entry_number>
 set lease-time <seconds>
 next
end
```

The default lease time is seven days. To have an unlimited lease time, set the value to zero.

## Configuring the DHCP renew time

You can set a minimum DHCP renew time. This option is available only when `mode` is set to `dhcp`.

To set the DHCP renew time, using the following CLI commands:

```
config system interface
 edit <name>
 set mode dhcp
 set dhcp-renew-time <seconds>
 next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

## DHCP options

When you add a DHCP server, you can include DHCP codes and options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you may need to configure a FortiGate DHCP server that gives out a separate option, as well as an IP address, such as an environment that needs to support PXE boot with Windows images.

The option numbers and codes are specific to a particular application. The documentation for the application should provide the values you should use. Option codes are represented in option value and HEX value pairs. The option is a value between 1 and 255.

You can add up to three DHCP code/option pairs per DHCP server.

### To configure option 252 with value `http://192.168.1.1/wpad.dat` (FortiGate CLI)

```
config system dhcp server
 edit <server_entry_number>
 set option1 252 687474703a2f2f3139322e3136382e312e312f777061642e646174
 end
```

For more information about DHCP options, see [RFC 2132](#) (DHCP Options and BOOTP Vendor Extensions).

### FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other `ddns` related options.

## DHCP server option fields

In place of specific fields, the DHCP server maintains a table for the potential options. The FortiOS DHCP server supports up to a maximum of 30 custom options. These optional fields are set in the CLI.

To get to the DHCP server, use the following CLI commands:

```
config system dhcp server
 edit <integer - ID of the specific DHCP server>
```

To configure the options, use the following CLI command:

```
config options
```

Once you are in the options context, create an ID for the table entry, using the following CLI commands:

```
edit <integer>
 set code <integer between 0 - 4294967295 to determine the DHCP option>
 set type [hex | string | ip]
 set value <option content for DHCP option types hex and string>
 set ip <option content for DHCP option type ip>
end
```

## Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users.

To do this, use the following CLI commands:

```

config system dhcp server
 edit <server_entry_number>
 config exclude-range
 edit <sequence_number>
 set start-ip <address>
 set end-ip <address>
 end
 end
 end
end

```

## Viewing information about DHCP server connections

To view information about DHCP server connections, go to **Monitor > DHCP Monitor**. On this page, you can also add IP addresses to the reserved IP address list.

## Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times, when some leases are no longer necessary, for example, with corporate visitors.

To break a lease, use the following CLI command:

```
execute dhcp lease-clear <ip_address>
```

## Interface MTU packet size

You can change the maximum transmission unit (MTU) of the packets that FortiGate transmits to improve network performance. Ideally, the MTU should be the same as the smallest MTU of all the networks between FortiGate and the destination of the packets. If the packets that the FortiGate unit sends are larger than the smallest MTU, they are broken up or fragmented, which slows down transmission. You can easily experiment by lowering the MTU to find an MTU size for optimum network performance.

- 68 to 1500 bytes for static mode
- 576 to 1500 bytes for DHCP mode
- 576 to 1492 bytes for PPPoE mode
- Larger frame sizes (if supported by the FortiGate model), up to 9216 bytes for NP2, NP4, and NP6-accelerated interfaces

This option is available only for physical interfaces. Virtual interfaces associated with a physical interface inherit the physical interface MTU size.

Interfaces on some FortiGate models support frames larger than the traditional 1500 bytes. Jumbo frames are supported on FortiGate models that have either a SOC2 or NP4lite (except for the FortiGate 30D), and on FortiGate 100D series models.

If you need to send larger frames over a route, all Ethernet devices on that route must support the larger frame size. Otherwise, the larger frames will not be recognized and will be dropped.

If you have standard size and larger size frame traffic on the same interface, routing alone cannot route them to different routes based only on frame size. However, you can use VLANs to make sure the larger frame traffic is routed over network devices that support the larger size. VLANs inherit the MTU size from the parent interface. You must configure the VLAN to include both ends of the route, as well as all switches and routers along the route.

You can configure the MTU packet size. If you select an MTU size larger than your FortiGate model supports, an error message will indicate this. In this situation, try configuring a smaller MTU size until the value is supported.

In transparent mode, if you change the MTU of an interface, you must change the MTU of all interfaces on FortiGate to match the new MTU.

To change the MTU size, use the following CLI commands:

```
config system interface
 edit <interface_name>
 set mtu-override enable
 set mtu <byte_size>
 end
```

## Interface settings

You configure FortiGate interfaces, both physical and virtual, in **Network > Interfaces** in the FortiGate GUI. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

On FortiOS Carrier, you can also enable the Gi gatekeeper on each interface for anti-overbilling.

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IP/Netmask</b>            | <p>The current IP address and netmask of the interface.</p> <p>In VDOM, when VDOMs are not all in NAT or transparent mode, some values may not be available for display and are displayed as “-”.</p>                                                                                                                                                                                                                                                                                                                                                           |
| <b>Access</b>                | The administrative access configuration for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Administrative Status</b> | <p>Indicates if the interface can be accessed for administrative purposes. If the administrative status is a green arrow, an administrator can connect to the interface using the configured access.</p> <p>If the administrative status is a red arrow, the interface is administratively down and cannot be accessed for administrative purposes.</p>                                                                                                                                                                                                         |
| <b>Link Status</b>           | <p>The status of the interface physical connection. The link status can be up (green arrow) or down (red arrow). If the link status is up, the interface is connected to the network and accepting traffic. If the link status is down, the interface is either not connected to the network or there is a problem with the connection.</p> <p>You cannot change the link status from the FortiGate GUI, and it typically indicates that an Ethernet cable is plugged into the interface.</p> <p>The link status is only displayed for physical interfaces.</p> |
| <b>MAC</b>                   | The MAC address of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mode</b>                  | The addressing mode of the interface. This value can be manual, DHCP, or PPPoE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Secondary IP</b>          | The secondary IP addresses added to the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>MTU</b>                   | The maximum number of bytes per transmission unit for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Virtual Domain</b>        | The virtual domain to which the interface belongs. This column is visible when VDOM configuration is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>VLAN ID</b>               | The configured VLAN ID for VLAN subinterfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Interface configuration and settings

To configure an interface, go to **Network > Interfaces**, and select **Create New**.

|             |                                                                              |
|-------------|------------------------------------------------------------------------------|
| <b>Name</b> | Enter the name of the interface. Physical interface names cannot be changed. |
|-------------|------------------------------------------------------------------------------|

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Alias</b>                      | <p>Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface.</p> <p>The alias is a maximum of 25 characters. The alias name does not appear in logs.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Link Status</b>                | <p>Indicates whether the interface is connected to a network (link status is <b>Up</b>) or not (link status is <b>Down</b>). This field appears when you edit an existing physical interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Type</b>                       | <p>Select the type of interface you want to add.</p> <p>On some FortiGate models, you can set <b>Type</b> to <b>802.3ad Aggregate</b> or <b>Redundant Interface</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Interface</b>                  | <p>This is displayed when <b>Type</b> is set to <b>VLAN</b>.</p> <p>Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the Interface list.</p> <p>You cannot change the physical interface of a VLAN interface except when you add a new VLAN interface.</p>                                                                                                                                                                                                                                    |
| <b>VLAN ID</b>                    | <p>This is displayed when <b>Type</b> is set to <b>VLAN</b>.</p> <p>Enter the VLAN ID. You cannot change the <b>VLAN ID</b> except when you add a new VLAN interface.</p> <p>The VLAN ID must be a number between 1 and 4094. It must match the VLAN ID that the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface adds.</p>                                                                                                                                                                                                                                                |
| <b>Virtual Domain</b>             | <p>Select the virtual domain to add the interface to.</p> <p>Administrator accounts with the super_admin profile can change the <b>Virtual Domain</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Physical Interface Members</b> | <p>This section can have two different formats depending on the interface type:</p> <ul style="list-style-type: none"><li>• <b>Software switch interface:</b> This section is a display-only field that shows the interfaces that belong to the virtual interface of the software switch.</li><li>• <b>802.3ad aggregate or Redundant interface:</b> This section includes the available interface list and the selected interface list.</li></ul> <p>Select interfaces from the <b>Available Interfaces</b> list and select the right arrow to add an interface to the <b>Selected Interface</b> list.</p> |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Addressing mode</b>       | <p>Select the addressing mode for the interface:</p> <ul style="list-style-type: none"> <li>• Select <b>Manual</b> and add an <b>IP/Netmask</b> for the interface. If IPv6 configuration is enabled, you can add both a IPv4 and an IPv6 IP address.</li> <li>• Select <b>DHCP</b> to get the interface IP address and other network settings from a DHCP server.</li> <li>• Select <b>PPPoE</b> to get the interface IP address and other network settings from a PPPoE server.</li> <li>• Select <b>One-Arm Sniffer</b> to enable the interface as a means to detect possible traffic threats. This option is available on physical ports that are not configured for the primary Internet connection.</li> <li>• Select <b>Dedicate to FortiAP/FortiSwitch</b> to have a FortiAP or FortiSwitch device connect exclusively to the interface. This option is available only when you edit a physical interface and it has a static IP address. When you enter the IP address, FortiGate automatically creates a DHCP server using the subnet that you enter. This option is not available on the ADSL interface.</li> </ul> <p>The FortiSwitch option is currently available only on the FortiGate 100D.</p> |
| <b>IP/Netmask</b>            | If <b>Addressing Mode</b> is set to <b>Manual</b> , enter an IPv4 address and subnet mask for the interface. FortiGate interfaces cannot have IP addresses on the same subnet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>IPv6 Address</b>          | If <b>Addressing Mode</b> is set to <b>Manual</b> and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Administrative Access</b> | Select the types of administrative access that you want to allow for IPv4 connections to this interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>HTTPS</b>                 | Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option will enable automatically when you select the <b>HTTP</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PING</b>                  | The interface responds to pings. Use this setting to verify your installation and for testing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>HTTP</b>                  | Allow HTTP connections to the FortiGate GUI through this interface. If configured, this option will also enable the <b>HTTPS</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SSH</b>                   | Allow SSH connections to the CLI through this interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SNMP</b>                  | Allow a remote SNMP manager to request SNMP information by connecting to this interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>FMG-Access</b>            | Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CAPWAP</b>                               | Allows the FortiGate wireless controller to manage a wireless access point, such as a FortiAP device.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>IPv6 Administrative Access</b>           | Select the types of administrative access that you want to allow for IPv6 connections to this interface. The types are the same as for Administrative Access.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Security Mode</b>                        | Select a captive portal for the interface. After you select this, you can define the portal message and the appearance of the GUI that users see when they log into the interface. You can also define one or more user groups that can access the interface.                                                                                                                                                                                                                                                                      |
| <b>DHCP Server</b>                          | Select this to enable a DHCP server for the interface. For more information about configuring a DHCP server on the interface, see <a href="#">DHCP servers and relays</a> .                                                                                                                                                                                                                                                                                                                                                        |
| <b>Device Detection</b>                     | Select this to allow the interface to be used with BYOD devices, such as iPhones. Define the device definitions by selecting <b>User &amp; Device &gt; Device Inventory</b> in the FortiGate GUI.                                                                                                                                                                                                                                                                                                                                  |

If you assign an interface to be part of a virtual wire pairing, the "role" value is removed from the interface.

## Loopback interfaces

A loopback interface is a logical interface that is always up (no physical link dependency) and the attached subnet is always present in the routing table.

The IP address of the FortiGate loopback interface does not depend on one specific external port, and therefore you can access it through several physical or VLAN interfaces. You can configure multiple loopback interfaces in either non-VDOM mode or in each VDOM.

Loopback interfaces still require appropriate firewall policies to allow traffic to and from the interfaces.

A loopback interface can be used with:

- Management access
- BGP (TCP) peering
- PIM RP

Loopback interfaces are a good practice for OSPF. To make troubleshooting OSPF easier, you should set the OSPF router ID the same as the loopback IP address, and remember the management IP addresses (ssh to “router ID”).

You can enable dynamic routing protocols on loopback interfaces.

For black hole static routes, use the black hole route type instead of the loopback interface.

### VXLAN loopback binding

A Virtual Extensible LAN (VXLAN) unicast device can bind to a loopback interface as its underlying interface. The IP address of the loopback interface is taken as the source IP address for its outgoing VXLAN packets so the peer knows where to reply. Among the parameters that are passed to the kernel, the ifindex of the loopback interface is not passed down to the kernel, so the kernel can choose the outgoing physical interface. This way, VXLAN traffic can be routed across multiple physical links and it provides resistance to a single point of failure.

You can configure VXLAN loopback binding, using the following CLI commands:

```
config system vxlan
edit <name>
 set interface <interface>
 set vni <VXLAN network ID>
 set remote-ip <IP address>
next
end
```

### One-armed sniffer

You can use a one-armed sniffer to configure a FortiGate physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured IPS sensor and application control list. Matches are logged and then all received traffic is dropped. Sniffing reports only on attacks. It does not deny or otherwise influence traffic.

You can use the one-arm sniffer to configure FortiGate to operate as an IDS appliance by sniffing network traffic for attacks without actually processing the packets. To configure one-arm IDS, you enable sniffer mode on a FortiGate interface and connect the interface to a hub, or to the SPAN port of a switch that is processing network traffic.

To assign an interface as a sniffer interface, select **Network > Interfaces**, edit the interface and select **One-Arm Sniffer**.

If the check box is not available, it means the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs, or other features in which a physical interface is specified.

| Field                         | Description                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable Filters</b>         | <p>Select this to include filters that define a more granular sniff of network traffic. Select specific hosts, ports, VLANs, and protocols.</p> <p>In all cases, enter a number or number range for the filtering type. For protocol values, the standard protocols are:</p> <ul style="list-style-type: none"><li>• UDP - 17</li><li>• TCP - 6</li><li>• ICMP - 1</li></ul> |
| <b>Include IPv6 Packets</b>   | If your network is running both IPv4 and IPv6 addressing, select this to sniff both addressing types. Otherwise, FortiGate will sniff only IPv4 traffic.                                                                                                                                                                                                                     |
| <b>Include Non-IP Packets</b> | Select this for a more intense scan of content in the traffic.                                                                                                                                                                                                                                                                                                               |
| <b>Security Profiles</b>      | IPS sensors and application control lists allow you to select specific sensors and applications that you want to identify within the traffic.                                                                                                                                                                                                                                |

## Ports preassigned as sniffer ports

Some FortiGate models have ports preconfigured as sniffer ports, by default. The models and ports preconfigured in sniffer mode are as follows:

- FortiGate 300D
  - Port4
  - Port8
- FortiGate 500D
  - Port5
  - Port6
  - Port13
  - Port14

## Physical ports

FortiGate has several physical ports that you can connect Ethernet or optical cables to. Depending on the FortiGate model, it can have between 4 and 40 physical ports. Some units have a grouping of ports labeled as **lan**, that provide built-in switch functionality.

The port names, as labeled on FortiGate, appear in the FortiGate GUI in the **Unit Operation** widget on the dashboard. They also appear when you configure the interfaces, in **Network > Interfaces**.

You can hover over the ports to see information about each port, such as the name of the port and the IP address.

For example, the following diagram shows the 22 interfaces of the FortiGate 100 D (Generation 2) as they appear in the dashboard in the FortiGate GUI.

Two of the physical ports on the FortiGate 100D (Generation 2) are SFP ports. These ports share the numbers 15 and 16 with RJ-45 ports. Because of this, when SFP port 15 is used, RJ-45 port 15 cannot be used, and vice versa. These ports also share the same MAC address.

## Configuring the FortiGate 100D ports

Normally, you can configure the internal interface as a single interface that is shared by all physical interface connections (a switch). The switch mode feature has two states: switch mode and interface mode. Switch mode is the default mode, with only one interface and one address for the entire internal switch. Interface mode allows you to configure each of the physical interface connections of the internal switch separately. This allows you to assign different subnets and netmasks to each of the internal physical interface connections.

The larger FortiGate models may also include Advanced Mezzanine Cards (AMC), which can provide additional interfaces (Ethernet or optical, with throughput enhancements for more efficient handling of specialized traffic). These interfaces appear in FortiOS as port `amc/sw1`, `amc/sw2`, and so on.

## Displaying information about the status of transceivers

You can display information about the status of transceivers installed in FortiGate SFP/SFP+ interfaces, in the FortiGate CLI.

The `get system interface transceiver` command lists all of the SFP/SFP+ interfaces on FortiGate. If the interfaces include transceivers, the command output displays information about them, such as the vendor name, part number, and serial number. It also includes details about transceiver operation, such as temperature, voltage, and optical transmission power, which you can use to diagnose transmission problems.

The following example shows an output from using this command:

```
get system interface transceiver
...
Interface port14 - Transceiver is not detected.
Interface port15 - SFP/SFP+
```

```

Vendor Name : FIBERXON INC.
Part No. : FTM-8012C-SLG
Serial No. : 101680071708917
Interface port16 - SFP/SFP+
Vendor Name : FINISAR CORP.
Part No. : FCLF-8521-3
Serial No. : PS62ENQ

```

| SFP/SFP+<br>Interface | Temperature<br>(Celsius) | Voltage<br>(Volts) | Optical<br>Tx Bias<br>(mA) | Optical<br>Tx Power<br>(dBm) | Optical<br>Rx Power<br>(dBm) |
|-----------------------|--------------------------|--------------------|----------------------------|------------------------------|------------------------------|
| port15                | N/A                      | N/A                | N/A                        | N/A                          | N/A                          |
| port16                | N/A                      | N/A                | N/A                        | N/A                          | N/A                          |

++ : high alarm, + : high warning, - : low warning, -- : low alarm, ? : suspect.

You can use this command on most FortiGate models that have SFP/SFP+ interfaces.

## Split port support

The 5001D 40 GB can be split into 4 10 GB ports. You can do this through a combination of hardware and software configuration. You use a specific 40 GB connector to connect to the 40 GB port and typically, the other end of the fibre optic cable connects to another 40 GB port. However, you can use a special cable that is a single 40 GB connector at one end and 4 10 GB connections at the other end. To use this setup, you also have to configure the port to be a split port.

You can configure this, using the following CLI commands:

```

config system global
 set port-split port1 port2
end

```

The ports will be checked to make sure that they are not in use or referenced by other policy configurations. If they are in use, the command is aborted. Changing the port to be a split port requires a system reboot.

## PPPoE addressing mode on an interface

If you configure the interface to use PPPoE, the FortiGate unit automatically broadcasts a PPPoE request from the interface.

The FortiGate units support many PPPoE RFC features (RFC 2516) including unnumbered IPs, initial discovery timeout and PPPoE Active Discovery Terminate (PADT).

PPPoE is only configurable in the web-based manager on desktop FortiGate units. 1U FortiGates and up must be configured in the CLI using the commands:

```

config system interface
 edit <port_name>
 set mode pppoe
 set username <ISP_username>
 set password <ISP_password>
 set idle-timeout <seconds>
 set distance <integer>
 set ipunnumbered <unnumbered-IP>
 set disc-retry-timeout <seconds>
 set padt-retry-timeout <seconds>
 end
end

```

```

set lcp-echo-interval <seconds>
set dns-server-override {enable | disable}
end

```

Configure PPPoE on an interface in **Network > Interfaces**. The following table describes the PPPoE status information when PPPoE is configured for an interface.

| Field                       | Description                                                                                                                                                                                                                                                                                                       |

| <b>Connecting</b>           | The interface is attempting to connect to the PPPoE server.                                                                                                                                                                                                                                                       |
| <b>Connected</b>            | <p>The interface retrieves an IP address, netmask, and other settings from the PPPoE server.</p> <p>When the status is connected, PPPoE connection information is displayed.</p>                                                                                                                                  |
| <b>Failed</b>               | The interface was unable to retrieve an IP address and other information from the PPPoE server.                                                                                                                                                                                                                   |
| <b>Reconnect</b>            | <p>Select to reconnect to the PPPoE server.</p> <p>Only displayed if Status is connected.</p>                                                                                                                                                                                                                     |
| <b>User Name</b>            | The user name for the PPPoE account.                                                                                                                                                                                                                                                                              |
| <b>Password</b>             | The password for the PPPoE account.                                                                                                                                                                                                                                                                               |
| <b>Unnumbered IP</b>        | Specify the IP address for the interface. If your ISP has assigned you a block of IP addresses, use one of them. Otherwise, this IP address can be the same as the IP address of another interface or can be any IP address.                                                                                      |
| <b>Initial Disc Timeout</b> | Enter Initial discovery timeout. Enter the time to wait before starting to retry a PPPoE discovery.                                                                                                                                                                                                               |
| <b>Initial PADT timeout</b> | Enter Initial PPPoE Active Discovery Terminate (PADT) timeout, in seconds. Use this timeout to shut down the PPPoE session if it is idle for the specified number of seconds. PADT must be supported by your ISP. Set the Initial PADT timeout to 0 to disable.                                                   |

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Distance</b>                             | Enter the administrative distance for the default gateway retrieved from the PPPoE server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route. The default distance for the default gateway is 1. |
| <b>Retrieve default gateway from server</b> | Enable to retrieve a default gateway IP address from a PPPoE server. The default gateway is added to the static routing table.                                                                                                                                                                                                                                         |
| <b>Override internal DNS</b>                | <p>Enable to replace the DNS server IP addresses on the System DNS page with the DNS addresses retrieved from the PPPoE server.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>                                                                                                                                      |

## Probing interfaces

Server probes can be used on interfaces. In order for this to occur, the probe response mode must first be configured, then the probe response must be allowed administrative access on the interface. The probe response mode can be one of the following:

| Mode       | Description                         |
|------------|-------------------------------------|
| none       | Disable probe                       |
| http-probe | HTTP probe                          |
| twamp      | Two-Way Active Measurement Protocol |

Both steps must be done through the CLI.

### Configuring the probe

```
config system probe-response
 set mode http-probe
end
```

### Allowing the probe response to have administrative access to the interface

```
config system interface
 edit <port>
 set allowaccess probe-response
 end
```

## Enhanced TWAMP Light functionality with server/controller functionality

TWAMP(Two-Way Active Measurement Protocol) Light is a simplified architecture within the TWAMP standard. Its purpose is to measure the round trip IP performance between any two devices within a network that supports

the protocol. FortiOS operates in more than just the role of responder/reflector. The server/controller functionality has been added.

## Redundant interfaces

On some models, you can combine two or more physical interfaces to provide link redundancy. This feature allows you to connect to two or more switches to ensure connectivity if one physical interface, or the equipment on that interface, fails.

In a redundant interface, traffic travels only over one interface at a time. This differs from an aggregated interface where traffic travels over all interfaces for distribution of increased bandwidth. This difference means that redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface can be in a redundant interface if:

- It is a physical interface, not a VLAN interface
- It is not already part of an aggregated or redundant interface
- It is in the same VDOM as the redundant interface
- It has no defined IP address
- It is not configured for DHCP or PPPoE
- It has no DHCP server or relay configured on it
- It does not have any VLAN subinterfaces
- It is not referenced in any security policy, VIP, or multicast policy
- It is not monitored by HA
- It is not one of the FortiGate-5000 series backplane interfaces

When an interface is included in a redundant interface, it is not listed on the **Network > Interfaces** page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

## Dual Internet connections

Dual internet connections, also referred to as dual WAN or redundant Internet connections, refers to using two FortiGate interfaces to connect to the Internet. Dual Internet connections can be used in three ways:

- Redundant interfaces: if one interface goes down, the second interface automatically becomes the main Internet connection
- Load sharing: to ensure better throughput
- Combination of redundancy and load sharing

### Redundant interfaces

Redundant interfaces ensure that if your Internet access is no longer available through a certain port, the FortiGate unit will use an alternate port to connect to the Internet.

#### Configuring redundant interfaces

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you need to configure three settings:

- Configure a link health monitor to determine when the primary interface (WAN1) is down and when the connection returns
- Configure a default route for each interface
- Configure security policies to allow traffic through each interface to the internal network

### Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor will confirm the connectivity of the device's interface.

#### To add a link health monitor

```
config system link-monitor
edit "Example1"
 set srcint <Interface_sending_probe>
 set server <ISP_IP_address>
 set protocol <Ping or http>
 set gateway-ip <the_gateway_IP_to_reach_the_server_if_required>
 set failtime <failure_count>
 set interval <seconds>
 set update-cascade-interface enable
 set update-static-route enable
 set status enable
end
```

### Routing

You need to configure a default route for each interface and indicate which route is preferred by specifying the distance. The lower distance is declared active and placed higher in the routing table.

When you have dual WAN interfaces that are configured to provide failover, you might not be able to connect to the backup WAN interface because the FortiGate unit may not route traffic (even responses) out of the backup interface. The FortiGate unit performs a reverse path lookup to prevent spoofed traffic. If an entry cannot be found in the routing table that sends the return traffic out the same interface, the incoming traffic is dropped.

#### To configure the routing of the two interfaces - web-based manager

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

|                                |                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Destination IP/Mask</b>     | For an IPv4 route, enter a subnet of 0 . 0 . 0 . 0 / 0 . 0 . 0 . 0<br>For an IPv6 route, enter a subnet of : : / 0 |
| <b>Gateway</b>                 | Enter the gateway address                                                                                          |
| <b>Interface</b>               | Select the primary connection. For example, <b>WAN1</b> .                                                          |
| <b>Administrative Distance</b> | Leave as the default of 10.                                                                                        |

3. Repeat these steps to set **Interface** to **WAN2** and **Administrative Distance** to 20.

### To configure the IPv4 routing of the two interfaces - CLI

```
config router static
 edit 0
 set dst 0.0.0.0 0.0.0.0
 set device WAN1
 set gateway <gateway_address>
 set distance 10
 next
 edit 0
 set dst 0.0.0.0 0.0.0.0
 set device WAN2
 set gateway <gateway_address>
 set distance 20
 next
end
```

### To configure the IPv6 routing of the two interfaces - CLI

```
config router static6
 edit 0
 set dst ::/0
 set device WAN1
 set gateway <gateway_address>
 set distance 10
 next
 edit 0
 set dst ::/0
 set device WAN2
 set gateway <gateway_address>
 set distance 20
 next
end
```

## Security policies

When creating security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic will be allowed to pass through WAN2 as it did with WAN1. This ensures that failover will occur with minimal effect to users. For more information about creating security policies, see the Firewall Guide.

## Load sharing

Load sharing allows you to use both connections to the Internet at the same time, but does not provide failover support. When configuring load sharing, you need to make sure that routing is configured for both external ports (for example, WAN1 and WAN2) have static routes with the same distance and priority.

For more information about load sharing, see the Advanced Routing Guide.

## Link redundancy and load sharing

In this scenario, both links are available to distribute Internet traffic over both links. Should one of the interfaces fail, the FortiGate unit will continue to send traffic over the other active interface. Configuration is similar to the Redundant interfaces configuration, with the main difference being that the configured routes should have equal distance settings.

This means both routes will remain active in the routing table. To make one interface the preferred interface, use a default policy route to indicate the interface that is preferred for accessing the Internet. If traffic matches the security policy, the policy overrides all entries in the routing table, including connected routes. You may need to add specific policy routes that override these default policy routes.

To redirect traffic over the secondary interface, create policy routes to direct some traffic onto it rather than the primary interface. When adding the policy route, only define the outgoing interface and leave the gateway blank. This ensures that the policy route will not be active when the link is down.

### SSL VPN and WAN link load balancing

You can set virtual WAN link interfaces as destination interfaces in firewall policies for WAN link load balancing, when SSL VPN is the source interface. For example, you can log in to FortiGate using an SSL VPN for traffic inspection and then have outbound traffic load balanced by WAN link load balancing.

You can set a virtual WAN link interface as a destination interface in a firewall policy where SSL VPN is the source interface, using either the FortiGate GUI (FortiOS 5.6.1 and later) or CLI.

In the CLI, use the following CLI commands:

```
config firewall policy
 edit <policy_id>
 set dstintf virtual-wan-link
 end
```

### Secondary IP addresses to an interface

If an interface is configured with a manual or static IP address, you can also add secondary static IP addresses to the interface. Adding secondary IP addresses effectively adds multiple IP addresses to the interface. Secondary IP addresses cannot be assigned using DHCP or PPPoE.

All of the IP addresses added to an interface are associated with the single MAC address of the physical interface, and all secondary IP addresses are in the same VDOM as the interface that they are added to. You configure interface status detection for gateway load balancing separately for each secondary IP addresses. As with all other interface IP addresses, secondary IP addresses cannot be on the same subnet as any other primary or secondary IP address assigned to a FortiGate interface unless they are in separate VDOMs.

To configure a secondary IP address, go to **Network > Interfaces**, select **Edit** or **Create New** and select the **Secondary IP Address** check box.

### Software switch

A software switch, or soft switch, is a virtual switch that is implemented at the software, or firmware level, rather than the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, using a software switch, you can place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration such as additional security policies, on the FortiGate unit.

It can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2 and DMZ interfaces, and you need one more port, you can create a soft switch that can include the 4-port switch and the DMZ interface all on the same subnet. These types of applications also apply to wireless interfaces and virtual wireless interfaces and physical interfaces such as those with FortiWiFi and FortiAP unit.

Similar to a hardware switch, a software switch functions like a single interface. A software switch has one IP address; all of the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface are not regulated by security policies, and traffic passing in and out of the switch are affected by the same policy.

There are a few things to consider when setting up a software switch:

- Ensure you create a backup of the configuration.
- Ensure you have at least one port or connection such as the console port to connect to the FortiGate unit. If you accidentally combine too many ports, you will need a way to undo any errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit. For example, DHCP servers, security policies, and so on.
- For increased security, you can create a captive portal for the switch, allowing only specific user groups access to the resources connected to the switch.
- To add an interface to a software switch, the interface cannot be referenced by the existing configuration. It must also have its IP address set to 0.0.0.0/0.0.0.0.

### To create a software switch - CLI

```
config system switch-interface
 edit <switch-name>
 set type switch
 set member <interface_list>
 end
config system interface
 edit <switch_name>
 set ip <ip_address>
 set allowaccess https ssh ping
 end
```

## Soft switch example

For this example, the wireless interface (Wi-Fi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless syncing from an iPhone and a local computer. The syncing between two subnets is problematic. By putting both interfaces on the same subnet, the syncing will work. The software switch will accomplish this.

In this example, the soft switch includes a wireless interface. Remember to configure any wireless security before proceeding. If you leave this interface open without any password or other security, it leaves open access to not only the wireless interface but to any other interfaces and devices connected within the software switch.

## Clear the interfaces and back up the configuration

First, ensure that the interfaces are not being used with any other security policy or other use on the FortiGate unit. Check the Wi-Fi and DMZ1 ports to ensure that DHCP is not enabled on the interface and there are no other dependencies with these interfaces.

Next, save the current configuration, in the event something does not work, recovery can be quick.

## Merge the interfaces

The plan is to merge the Wi-Fi port and DMZ1 port. This will create a software switch with a name of “synchro” with an IP address of 10.10.21.12. The following steps will create the switch, add the IP address and set administrative access for HTTPS, SSH, and Ping.

### To merge the interfaces - CLI

```
config system switch-interface
 edit synchro
 set type switch
 set member dmz1 wifi
 end
config system interface
 edit synchro
 set ip 10.10.21.12
 set allowaccess https ssh ping
 end
```

## Final steps

With the switch set up, you can add security policies, DHCP servers, and any other configuration that you would normally do to configure interfaces on the FortiGate unit.

## Virtual switch

Virtual switch feature enables you create virtual switches on top of the physical switch(es) with designated interfaces/ports so that a virtual switch can build up its forwarding table through learning and forward traffic accordingly. When traffic is forwarded among interfaces belonging to the same virtual switch, the traffic does not need to go up to the software stack, but is forwarded directly by the switch. When traffic has to be relayed to interfaces not on the virtual switch, the traffic will go through the normal data path and be offloaded to NP4, when possible.

This feature is only available on mid- to high-end FortiGate units, including the 100D, 600C, 1000C, and 1240B.

### To enable and configure the virtual switch, enter the following CLI commands:

```
config system virtual-switch
 edit vs1
 set physical-switch sw0
 config port
 edit 1
 set port port1
 set speed xx
 set duplex xx
 set status [up|down]
 edit 2
 set port port2
 set ...
 end
 end
 end
```

## Support for 802.1x fallback and 802.1x dynamic VLANs

There are four modes when enabling 802.1x on a virtual switch interface:

| Mode         | Description                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default      | In this mode, it works as it did previously.                                                                                                                                                                                                                                                                                        |
| Fallback     | In fallback mode, the virtual switch will be treated as a master. Only one slave can refer to a fallback master. Those ports in the master virtual switch are always authorized. After passing 802.1x authentication, the ports will stay authorized and moved to its slave virtual switch.                                         |
| Dynamic-vlan | In dynamic-vlan mode, the virtual switch will also be treated as a master. However, many slaves can refer to a dynamic-vlan master. Those ports in the master virtual switch are always un-authorized. After passing 802.1x/MAB authentication, the ports will be set to authorized and moved to one of its slave virtual switches. |
| Slave        | In slave mode, a master must be set through security-8021x-master attribute. A slave virtual switch will use its master virtual switch's security-groups settings for authentication.                                                                                                                                               |

CLI example for fallback mode:

```

config system virtual-switch
 edit "fallsw"
 set physical-switch "sw0"
 config port
 end
 edit "trust"
 set physical-switch "sw0"
 end
config system interface
 edit "fallsw"
 set vdom "root"
 set ip 192.168.20.1 255.255.255.0
 set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
 probereponse capwap
 set type hard-switch
 set security-mode 802.1X
 set security-8021x-mode fallback(fallback mode master switch)
 set security-groups "rds-grp"(the usergroup for 802.1x)
 set snmp-index 10
 next
 edit "trust"
 set vdom "root"
 set ip 192.168.22.1 255.255.255.0
 set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
 probereponse
 set type hard-switch
 set security-mode 802.1X
 set security-8021x-mode slave(slave mode switch)
 set security-8021x-master "fallsw" (its master switch)
 set snmp-index 6
 next
end

```

**CLI example for dynamic-vlan mode:**

```
config system virtual-switch
edit "internal"
 set physical-switch "sw0"
edit "lan-trust"
 set physical-switch "sw0"
 next
edit "lan-vlan1000"
 set physical-switch "sw0"
 next
edit "lan-vlan2000"
 set physical-switch "sw0"
 config port
 edit "internal1" (normally we should not add port in slave switch. This is used if
user wants to manually add one port in slave)
 end
end
config system interface
edit "internal"
 set vdom "root"
 set ip 192.168.11.99 255.255.255.0
 set allowaccess ping https ssh http fgfm capwap
 set type hard-switch
 set security-mode 802.1X
 set security-8021x-mode dynamic-vlan<-----dynamic-vlan mode master switch
 set security-groups "rds-grp"<-----the usergroup for 802.1x
 set snmp-index 15
 next
edit "lan-trust"
 set vdom "root"
 set ip 192.168.111.99 255.255.255.0
 set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
 probereponse capwap
 set type hard-switch
 set security-mode 802.1X
 set security-8021x-mode slave<-----slave mode switch
 set security-8021x-master "internal"<-----its master switch
 set snmp-index 7
 next
edit "lan-vlan1000"
 set vdom "root"
 set ip 192.168.110.1 255.255.255.0
 set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
 probereponse capwap
 set type hard-switch
 set security-mode 802.1X
 set security-8021x-mode slave<-----slave mode switch
 set security-8021x-master "internal"<-----its master switch
 set security-8021x-dynamic-vlan-id 1000 <-----the matching vlan id for this virtual
switch
 set snmp-index 16
 next
edit "lan-vlan2000"
 set vdom "root"
 set ip 192.168.220.1 255.255.255.0
```

```

set allowaccess ping https ssh snmp http telnet fgfm auto-ipsec radius-acct
 proberesponse
capwap
set type hard-switch
set security-mode 802.1X
set security-8021x-mode slave
set security-8021x-master "internal"
set security-8021x-dynamic-vlan-id 2000
set snmp-index 17
end
config user group
 edit "rds-grp"
 set dynamic-vlan-id 4000 (default vlan id if there is no vlan attribute return
 from server)
 set member "190"
 end
end

```

## Zones

Zones are a group of one or more FortiGate interfaces, both physical and virtual, that you can apply security policies to control inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies the creation of security policies where a number of network segments can use the same policy settings and protection profiles. When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address and routing is still done between interfaces, that is, routing is not affected by zones. Security policies can also be created to control the flow of intra-zone traffic.

For example, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of port and VLANs, in each area, they can all use the same security policy and protection profiles to access the Internet. Rather than the administrator making nine separate security policies, the administrator can add the required interfaces to a zone and create three policies, making administration simpler.

You can configure policies for connections to and from a zone, but not between interfaces in a zone.

The following example shows how to set up a zone to include the internal interface and a VLAN.

### To create a zone - web-based manager

1. Go to **Network > Interfaces**.
2. Select the arrow on the **Create New** button and select **Zone**.
3. Enter a zone name of `Zone_1`.
4. Select the required **Interface Members**.
5. Select **OK**.

### To create a zone - CLI

```

config system zone
 edit Zone_1
 set interface internal VLAN_1
 end
end

```

## Virtual domains

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. A single FortiGate unit is then flexible enough to serve multiple departments of an organization, separate organizations, or to act as the basis for a service provider's managed security service.

VDOMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations. By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the FortiGate physical interfaces, modem, virtual LAN (VLAN) subinterfaces, zones, security policies, routing settings, and VPN settings.

When a packet enters a VDOM, it is confined to that VDOM. In a VDOM, you can create security policies for connections between VLAN subinterfaces or zones in the VDOM. Packets do not cross the virtual domain border internally. To travel between VDOMs, a packet must pass through a firewall on a physical interface. The packet then arrives at another VDOM on a different interface, but it must pass through another firewall before entering the VDOM. Both VDOMs are on the same FortiGate unit. Inter-VDOMs change this behavior because they are internal interfaces; however, their packets go through all the same security measures as on physical interfaces.

The following example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First, enable VDOMs on the FortiGate unit. When you enable VDOMs, the FortiGate unit will log you out.

For desktop and low-end FortiGate units, you use the CLI to enable VDOMs. Once you enable VDOMs, all further configuration can be done using the web-based manager or the CLI. On larger FortiGate units, you can use the web-based manager or the CLI to enable VDOMs.

### To enable VDOMs - web-based manager

1. Go to **Dashboard**.
2. In the **System Information** widget, select **Enable** for **Virtual Domain**.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all VDOMs:

### To enable VDOMs - CLI

```
config system global
 set vdom-admin enable
end
```

Next, add the VDOM called accounting.

### To add a VDOM - web-based manager

1. Go to **System > VDOM**, and select **Create New**.
2. Enter the VDOM name `accounting`.
3. Select **OK**.

### To add a VDOM - CLI

```
config vdom
 edit <new_vdom_name>
end
```

With the VDOM created, you can assign a physical interface to it, and assign it an IP address.

### To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to **Network > Interfaces**.
2. Select the DMZ2 port row and select **Edit**.
3. For the **Virtual Domain** drop-down list, select **accounting**.
4. Select the **Addressing Mode** of **Manual**.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the **Administrative Access** to **HTTPS** and **SSH**.
7. Select **OK**.

### To assign physical interface to the accounting Virtual Domain - CLI

```
config global
 config system interface
 edit dmz2
 set vdom accounting
 set ip 10.13.101.100/24
 set allowaccess https ssh
 next
 end
```

## VXLANs

Virtual Extensible LAN (VXLAN) is a network virtualization technology that's used in large cloud computing deployments. It encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets using the standard destination port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, and are known as VXLAN Tunnel Endpoints (VTEPs). For more information about VXLAN, see [RFC 7348](#).

### VTEP support

FortiOS supports native VXLAN. You can configure VXLANs in the FortiGate CLI.

```
config system vxlan
 edit <vxlan1> //VXLAN device name (Unique name in system.interface)
 set interface //Local outgoing interface
 set vni //VXLAN network ID
 set ip-version //IP version to use for VXLAN device
 set dstport //VXLAN destination port, default is 4789
 set multicast-ttl //VXLAN multicast TTL
 set remote-ip //Remote IP address of VXLAN
 next
end
```

This creates a VXLAN interface:

```
show system interface vxlan1
config system interface
 edit "vxlan1"
 set vdom "root"
 set type vxlan
 set snmp-index 36
 set macaddr 8a:ee:1d:5d:ae:53
 set interface "port9"
```

```
next
end
```

To verify the new VXLAN interface, go to **Network > Interfaces** in the FortiGate GUI.

| vxlan (1) |                 |                       |   |
|-----------|-----------------|-----------------------|---|
| vxlan1    | 0.0.0.0/0.0.0.0 | interface_type::vxlan | 0 |

To diagnose the VXLAN configuration, use the following command in the FortiGate CLI:

```
diagnose sys vxlan fdb list vxlan1
```

This command provides information about the VXLAN forwarding database (fdb) that's associated with the vxlan1 interface. The following is a sample output:

```
-----mac=00:00:00:00:00:00 state=0x0082 flags=0x00-----
-----remote_ip=2.2.2.2 remote_port=4789-----
-----remote_vni=1 remote_ifindex=19-----
total fdb num: 1
```

## VXLAN support for multiple remote IP addresses

VXLAN is supported for multiple remote IP addresses, which can be IPv4 unicast, IPv6 unicast, IPv4 multicast, or IPv6 multicast. This is useful in datacenter scenarios where you can configure the FortiGate with multiple tunnels to computer nodes.

### CLI changes

set ip-version option can be set to the following:

ipv4-unicast//Use IPv4 unicast addressing for VXLAN.

ipv6-unicast //Use IPv6 unicast addressing for VXLAN.

ipv4-multicast//Use IPv4 multicast addressing for VXLAN.

ipv6-multicast//Use IPv6 multicast addressing for VXLAN.

When ip-version is set to ipv4-multicast or ipv6-multicast, the ttl option is replaced by multicast-ttl.

## Wireless

A wireless interface is similar to a physical interface except it does not include a physical connection. The FortiWiFi units allow you to add multiple wireless interfaces that can be available at the same time. On FortiWiFi units, you can configure the device to be either an access point or a wireless client. As an access point, the FortiWiFi unit can have separate SSIDs, each on their own subnet for wireless access. In client mode, the FortiWiFi has only one SSID, and is used as a receiver to allow remote users to connect to the existing network using wireless protocols.

Wireless interfaces also require additional security measures to ensure the session does not get hijacked and data tampered or stolen.

For more information about configuring wireless interfaces see the *Deploying Wireless Networks Guide*.

## VLANs

Virtual Local Area Networks (VLANs) multiply the capabilities of your FortiGate unit, and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security. The IEEE 802.1Q standard defines VLANs. All layer-2 and layer-3 devices along a route must be 802.1Q-compliant to support VLANs along that route.

A Local Area Network (LAN) is a group of connected computers and devices that are arranged into network broadcast domains. A LAN broadcast domain includes all the computers that receive a packet broadcast from any computer in that broadcast domain. A switch will automatically forward the packets to all of its ports. In contrast, routers do not automatically forward network broadcast packets. This means routers separate broadcast domains. If a network has only switches and no routers, that network is considered one broadcast domain, no matter how large or small it is. Smaller broadcast domains are more efficient because fewer devices receive unnecessary packets. They are more secure as well because a hacker reading traffic on the network will have access to only a small portion of the network instead of the entire network's traffic.

VLANs reduce the size of the broadcast domains by only forwarding packets to interfaces that are part of that VLAN or part of a VLAN trunk link. Trunk links form switch-to-switch or switch-to-router connections, and forward traffic for all VLANs. This enables a VLAN to include devices that are part of the same broadcast domain, but physically distant from each other.

VLAN ID tags consist of a 4-byte frame extension that switches and routers apply to every packet sent and received in the VLAN. Workstations and desktop computers, which are commonly originators or destinations of network traffic, are not an active part of the VLAN process. All the VLAN tagging and tag removal is done after the packet has left the computer.

Any FortiGate unit without VDOMs enabled can have a maximum of 255 interfaces in transparent operating mode. The same is true for any single VDOM. In NAT mode, the number can range from 255 to 8192 interfaces per VDOM, depending on the FortiGate model. These numbers include VLANs, other virtual interfaces, and physical interfaces. To have more than 255 interfaces configured in transparent operating mode, you need to configure multiple VDOMs that enable you to divide the total number of interfaces over all the VDOMs.

One example of an application of VLANs is a company's accounting department. Accounting computers may be located at both main and branch offices. However, accounting computers need to communicate with each other frequently and require increased security. VLANs allow the accounting network traffic to be sent only to accounting computers and to connect accounting computers in different locations as if they were on the same physical subnet.

This guide uses the term "packet" to refer to both layer-2 frames and layer-3 packets.

On a layer-2 switch, you can have only one VLAN subinterface per physical interface, unless that interface is configured as a trunk link. Trunk links can transport traffic for multiple VLANs to other parts of the network.

On a FortiGate unit, you can add multiple VLANs to the same physical interface. However, VLAN subinterfaces added to the same physical interface cannot have the same VLAN ID or have IP addresses on the same subnet. You can add VLAN subinterfaces with the same VLAN ID to different physical interfaces.

Creating VLAN subinterfaces with the same VLAN ID does not create an internal connection between them. For example a VLAN ID of 300 on port1 and VLAN ID of 300 on port2 are allowed, but they are not connected. Their relationship is the same as between any two FortiGate network interfaces.

FortiGate unit interfaces cannot have overlapping IP addresses, the IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces such as VLAN

subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask. This rule helps prevent a broadcast storm or other similar network problems.

The following example shows how to add a VLAN, called `vlan_accounting`, on the FortiGate unit internal interface with an IP address of 10.13.101.101.

#### To add a VLAN - web-based manager

1. Go to **Network > Interfaces**.
2. Select **Create New** and click on **Interface**.  
The **Type** is set to VLAN, by default.
3. Enter a name for the **VLAN** to `vlan_accounting`.
4. Select the **Internal** interface.
5. Enter the **VLAN ID**.  
The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together.
6. Select the **Addressing Mode** of **Manual**.
7. Enter the IP address for the port of 10.13.101.101/24.
8. Set the **Administrative Access** to **HTTPS** and **SSH**.
9. Select **OK**.

#### To add a VLAN - CLI

```
config system interface
 edit VLAN_1
 set interface internal
 set type vlan
 set vlanid 100
 set ip 10.13.101.101/24
 set allowaccess https ssh
 next
end
```

### VLANs in NAT mode

In NAT mode the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs, but can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks, such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches, or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN sub-interfaces to the FortiGate unit physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to sub-interfaces with matching IDs.

You can define VLAN sub-interfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you will have access to only the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration the

FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

### Adding VLAN subinterfaces

A VLAN subinterface, also called a VLAN, is a virtual interface on a physical interface. The subinterface allows routing of VLAN tagged packets using that physical interface, but it is separate from any other traffic on the physical interface.

Adding a VLAN subinterface includes configuring:

- Physical interface
- IP address and netmask
- VLAN ID
- VDOM

### Physical interface

The term VLAN subinterface correctly implies the VLAN interface is not a complete interface by itself. You add a VLAN subinterface to the physical interface that receives VLAN-tagged packets. The physical interface can belong to a different VDOM than the VLAN, but it must be connected to a network router that is configured for this VLAN. Without that router, the VLAN will not be connected to the network, and VLAN traffic will not be able to access this interface. The traffic on the VLAN is separate from any other traffic on the physical interface.

When you are working with interfaces on your FortiGate unit, use the **Column Settings** on the Interface display to make sure the information you need is displayed. When working with VLANs, it is useful to position the **VLAN ID** column close to the IP address. If you are working with VDOMs, including the **Virtual Domain** column as well will help you troubleshoot problems more quickly.

To view the Interface display, go to **Network > Interfaces**.

### IP address and netmask

FortiGate unit interfaces cannot have overlapping IP addresses. The IP addresses of all interfaces must be on different subnets. This rule applies to both physical and virtual interfaces, such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask pair. This rule helps prevent a broadcast storm or other similar network problems.

If you are unable to change your existing configurations to prevent IP overlap, enter the CLI command `config system settings and set allow-subnet-overlap enable` to allow IP address overlap. If you enter this command, multiple VLAN interfaces can have an IP address that is part of a subnet used by another interface. This command is recommended for advanced users only.

### VLAN ID

The VLAN ID is part of the VLAN tag added to the packets by VLAN switches and routers. The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together. VLAN ID 0 is used only for high priority frames, and 4095 is reserved.

All devices along a route must support the VLAN ID of the traffic along that route. Otherwise, the traffic will be discarded before reaching its destination. For example, if your computer is part of VLAN\_100 and a co-worker on a different floor of your building is also on the same VLAN\_100, you can communicate with each other over VLAN\_100, only if all the switches and routers support VLANs and are configured to pass along VLAN\_100 traffic properly. Otherwise, any traffic you send to your co-worker will be blocked or will not be delivered.

## VDOM

If VDOMs are enabled, each VLAN subinterface must belong to a VDOM. This rule also applies for physical interfaces.

Interface-related CLI commands require a VDOM to be specified, regardless of whether the FortiGate unit has VDOMs enabled.

---

VLAN subinterfaces on separate VDOMs cannot communicate directly with each other. In this situation, the VLAN traffic must exit the FortiGate unit and re-enter the unit, passing through firewalls in both directions. This situation is the same for physical interfaces.

A VLAN subinterface can belong to a different VDOM than the physical interface it is part of. This is because the traffic on the VLAN is handled separately from the other traffic on that interface. This is one of the main strengths of VLANs.

The following procedure will add a VLAN subinterface called `VLAN_100` to the FortiGate internal interface with a VLAN ID of 100. It will have an IP address and netmask of `172.100.1.1/255.255.255.0`, and allow HTTPS and PING administrative access. Note that in the CLI, you must enter “`set type vlan`” before setting the `vlanid`, and that the `allowaccess` protocols are lower case.

### To add a VLAN subinterface in NAT mode - web-based manager

1. If **Current VDOM** appears at the bottom left of the screen, select **Global** from the list of VDOMs.
2. Go to **Network > Interfaces**.
3. Select **Create New** to add a VLAN subinterface.
4. Enter the following:

|                              |                           |
|------------------------------|---------------------------|
| <b>VLAN Name</b>             | VLAN_100                  |
| <b>Type</b>                  | VLAN                      |
| <b>Interface</b>             | internal                  |
| <b>VLAN ID</b>               | 100                       |
| <b>Addressing Mod</b>        | Manual                    |
| <b>IP/Netmask</b>            | 172.100.1.1/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS, PING, TELNET       |

5. Select **OK**.

To view the new VLAN subinterface, select the expand arrow next to the parent physical interface (the internal interface). This will expand the display to show all VLAN subinterfaces on this physical interface. If there is no expand arrow displayed, there are no subinterfaces configured on that physical interface.

For each VLAN, the list displays the name of the VLAN, and, depending on column settings, its IP address, the Administrative access you selected for it, the VLAN ID number, and which VDOM it belongs to if VDOMs are enabled.

### To add a VLAN subinterface in NAT mode - CLI

```
config system interface
edit VLAN_100
set interface internal
set type vlan
set vlanid 100
set ip 172.100.1.1 255.255.255.0
set allowaccess https ping
end
```

## Configuring security policies and routing

Once you have created a VLAN subinterface on the FortiGate unit, you need to configure security policies and routing for that VLAN. Without these, the FortiGate unit will not pass VLAN traffic to its intended destination. Security policies direct traffic through the FortiGate unit between interfaces. Routing directs traffic across the network.

### Configuring security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Interfaces that communicate with the VLAN interface need security policies to permit traffic to pass between them and the VLAN interface.

Each VLAN needs a security policy for each of the following connections the VLAN will be using:

- From this VLAN to an external network
- From an external network to this VLAN
- From this VLAN to another VLAN in the same virtual domain on the FortiGate unit
- From another VLAN to this VLAN in the same virtual domain on the FortiGate unit

The packets on each VLAN are subject to antivirus scans and other security profiles measures as they pass through the FortiGate unit.

### Configuring routing

As a minimum, you need to configure a default static route to a gateway with access to an external network for outbound packets. In more complex cases, you must configure different static or dynamic routes based on packet source and destination addresses.

As with firewalls, you must configure routes for VLAN traffic. VLANs need routing and a gateway configured to send and receive packets outside their local subnet just as physical interfaces do. The type of routing you configure, static or dynamic, will depend on the routing used by the subnet and interfaces you are connecting to. Dynamic routing can be routing information protocol (RIP), border gateway protocol (BGP), open shortest path first (OSPF), or multicast.

If you enable SSH, PING, HTTPS and HTTP on the VLAN, you can use those protocols to troubleshoot your routing and test that it is properly configured. Enabling logging on the interfaces and using CLI diagnose commands, such as `diagnose sniff packet <interface_name>`, can also help locate any possible configuration or hardware issues.

## VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering and intrusion protection to traffic. There are some limitations in transparent mode because you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

## VLANs and transparent mode

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, you create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features, such as spam filtering, web filtering, and anti-virus scanning, are applied through the Security Profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet at a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet, and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

## General configuration steps

There are two essential steps to configure your FortiGate unit to work with VLANs in transparent mode:

- [Add VLAN subinterfaces](#)
- [Create security policies](#)

You can also configure the Security Profiles that manage antivirus scanning, web filtering and spam filtering. For more information about Security Profiles, see the Security Profiles Guide.

## Add VLAN subinterfaces

The VLAN ID of each VLAN subinterface must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch. The VLAN ID can be any number between 1 and 4094, with 0 being used only for high priority frames and 4095 being reserved. You add VLAN subinterfaces to the physical interface that receives VLAN-tagged packets.

For this example, we are creating a VLAN called `internal_v225` on the internal interface, with a VLAN ID of 225. Administrative access is enabled for HTTPS and SSH. VDOMs are not enabled.

### To add VLAN subinterfaces in transparent mode - web-based manager

1. Go to **Network > Interfaces**.
2. Select **Create New** and click on **Interfaces**.
3. Enter the following information and select **OK**.

|                  |               |
|------------------|---------------|
| <b>Name</b>      | internal_v225 |
| <b>Type</b>      | VLAN          |
| <b>Interface</b> | internal      |
| <b>VLAN ID</b>   | 225           |

**Administrative Access** Enable HTTPS, and SSH. These are very secure access methods.

The FortiGate unit adds the new subinterface to the interface that you selected.

Repeat steps 2 and 3 to add additional VLANs. You will need to change the **VLAN ID**, **Name**, and possibly **Interface** when adding additional VLANs.

### To add VLAN subinterfaces in transparent mode - CLI

```
config system interface
 edit internal_v225
 set interface internal
 set vlanid 225
 set allowaccess HTTPS SSH
 set description "VLAN 225 on internal interface"
 set vdom root
 end
```

### Create security policies

In transparent mode, the FortiGate unit performs antivirus and antispam scanning on each VLAN's packets as they pass through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

### To add security policies for VLAN subinterfaces - web based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** to add firewall addresses that match the source and destination IP addresses of VLAN packets.
3. Go to **Policy & Objects > IPv4 Policy** or **Policy & Objects > IPv6Policy** and select **Create New**.
4. From the **Incoming Interface/Zone** list, select the VLAN interface where packets enter the unit.
5. From the **Outgoing Interface/Zone** list, select the VLAN interface where packets exit the unit.
6. Select the **Source** and **Destination** Address names that you added in step 2.
7. Select **OK**.

### To add security policies for VLAN subinterfaces - CLI

```
config firewall address
 edit incoming_VLAN_address
```

```
 set associated-interface <incoming_VLAN_interface>
 set type ipmask
 set subnet <IPv4_address_mask>
 next
 edit outgoing_VLAN_address
 set associated-interface <outgoing_VLAN_interface>
 set type ipmask
 set subnet <IPv4_address_mask>
 next
end
config firewall policy or config firewall policy6
 edit <unused_policy_number>
 set srcintf <incoming_VLAN_interface>
 set srcaddr incoming_VLAN_address
 set destintf <outgoing_VLAN_interface>
 set destaddr outgoing_VLAN_address
 set schedule always
 set service <protocol_to_allow_on_VLAN>
 set action ACCEPT
 next
end
```

## VLAN switching and routing

VLAN switching takes place on the Open Systems Interconnect (OSI) model layer-2, just like other network switching. VLAN routing takes place on the OSI model layer-3. The difference between them is that during VLAN switching, VLAN packets are simply forwarded to their destination. This is different from VLAN routing where devices can open the VLAN packets and change their VLAN ID tags to route the packets to a new destination.

### VLAN layer-2 switching

Ethernet switches are layer-2 devices, and generally are 802.1Q compliant. Layer 2 refers to the second layer of the seven layer OSI basic networking model, called the Data Link layer. FortiGate units act as layer-2 switches or bridges when they are in transparent mode. The units simply tag and forward the VLAN traffic or receive and remove the tags from the packets. A layer-2 device does not inspect incoming packets or change their contents; it only adds or removes tags and routes the packet.

A VLAN can have any number of physical interfaces assigned to it. Multiple VLANs can be assigned to the same physical interface. Typically two or more physical interfaces are assigned to a VLAN, one for incoming and one for outgoing traffic. Multiple VLANs can be configured on one FortiGate unit, including trunk links.

### VLAN layer-3 routing

Routers are layer-3 devices. Layer 3 refers to the third layer of the OSI networking model, the Network layer. FortiGate units in NAT mode act as layer-3 devices. As with layer 2, FortiGate units acting as layer-3 devices are 802.1Q-compliant.

The main difference between layer-2 and layer-3 devices is how they process VLAN tags. Layer-2 switches just add, read and remove the tags. They do not alter the tags or do any other high-level actions. Layer-3 routers not only add, read and remove tags but also analyze the data frame and its contents. This analysis allows layer-3 routers to change the VLAN tag if it is appropriate and send the data frame out on a different VLAN.

In a layer-3 environment, the 802.1Q-compliant router receives the data frame and assigns a VLAN ID. The router then forwards the data frame to other members of the same VLAN broadcast domain. The broadcast

domain can include local ports, layer-2 devices and layer-3 devices such as routers and firewalls. When a layer-3 device receives the data frame, the device removes the VLAN tag and examines its contents to decide what to do with the data frame. The layer-3 device considers:

- Source and destination addresses
- Protocol
- Port number

The data frame may be forwarded to another VLAN, sent to a regular non-VLAN-tagged network or just forwarded to the same VLAN as a layer-2 switch would do. Or, the data frame may be discarded if the proper security policy has been configured to do so.

## Layer-2 and ARP traffic

By default, FortiGate units do not pass layer-2 traffic. If there are layer-2 protocols such as IPX, PPTP or L2TP in use on your network, you need to configure your FortiGate unit interfaces to pass these protocols without blocking. Another type of layer-2 traffic is Address Resolution Protocol (ARP) traffic.

You can allow these layer-2 protocols using the CLI command:

```
config system interface
 edit <name_str>
 set l2forward enable
 end
```

where `<name_str>` is the name of an interface.

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as follows:

```
config vdom
 edit <vdom_name>
 config system interface
 edit <name_str>
 set l2forward enable
 end
 end
 end
```

If you enable layer-2 traffic, you may experience a problem if packets are allowed to repeatedly loop through the network. This repeated looping, very similar to a broadcast storm, occurs when you have more than one layer-2 path to a destination. Traffic may overflow and bring your network to a halt. You can break the loop by enabling Spanning Tree Protocol (STP) on your network's switches and routers.

## STP forwarding

The FortiGate unit does not participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, reducing available bandwidth to nothing.

If you use your FortiGate unit in a network topology that relies on STP for network loop protection, you need to make changes to your FortiGate configuration. Otherwise, STP recognizes your FortiGate unit as a blocked link and forwards the data to another path. By default, your FortiGate unit blocks STP as well as other non-IP protocol traffic.

Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the external interface:

```
config system interface
edit external
 set l2forward enable
 set stpforward enable
end
```

By substituting different commands for `stpforward enable`, you can also allow layer-2 protocols such as IPX, PPTP or L2TP to be used on the network.

## STP support for FortiGate models with hardware switches

STP (Spanning Tree Protocol) used to be available only on the old style switch mode for the internal ports. You can now activate STP on the hardware switches found in the newer FortiGate models. These models use a virtual switch to simulate the old switch Mode for the internal ports.

You can enable STP, using the following CLI commands:

```
config system interface
edit lan
 set stp [enable | disable]
end
```

## ARP traffic

Address Resolution Protocol (ARP) packets are vital to communication on a network and ARP support is enabled on FortiGate unit interfaces, by default. Normally you want ARP packets to pass through the FortiGate unit, especially if it is sitting between a client and a server or between a client and a router.

ARP traffic can cause problems, especially in transparent mode where ARP packets arriving on one interface are sent to all other interfaces including VLAN subinterfaces. Some layer-2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN. This instability can occur if the layer-2 switch does not maintain separate MAC address tables for each VLAN. Unstable switches may reset and cause network traffic to slow down considerably.

The default ARP timeout value is 5 minutes (300 seconds). So usually ARP entries are removed after 5 minutes. However, some conditions can cause ARP entries to remain on the list for a longer time. This is not a configurable value. To view the ARP list, enter the `get system arp` CLI command.

## Proxy ARP extensions

You can extend the proxy ARP configuration to an IP address range instead of a single IP address. When you configure `proxy-arp`, in addition to setting the IP address, you can also set the `end-ip` address. If you do not set this, the proxy ARP will be a single address, as before. The following is an example CLI configuration, using the new setting:

```
config system proxy-arp
edit 1
 set interface "internal"
 set ip 192.168.1.100
 set end-ip 192.168.1.102
end
```

## Multiple VDOMs solution

By default, physical interfaces are in the root domain. If you do not configure any of your VLANs in the root VDOM, it will not matter how many interfaces are in the root VDOM.

The multiple VDOMs solution is to configure multiple VDOMs on the FortiGate unit, one for each VLAN. In this solution, you configure one inbound and one outbound VLAN interface in each VDOM. ARP packets are not forwarded between VDOMs. This configuration limits the VLANs in a VDOM and correspondingly reduces the administration needed per VDOM.

As a result of this configuration, the switches do not receive multiple ARP packets with duplicate MACs. Instead, the switches receive ARP packets with different VLAN IDs and different MACs. Your switches are stable.

However, you should **not** use the multiple VDOMs solution under any of the following conditions:

- You have more VLANs than licensed VDOMs
- You do not have enough physical interfaces

Instead, use one of two possible solutions, both supported in transparent mode only:

- Use the `vlanforward` CLI command.
- Use the `forward-domain` CLI command. But you still need to be careful in some rare configurations.

## Vlanforward solution

By default, the `vlanforward` CLI command is enabled and will forward VLAN traffic to all VLANs on this interface. When disabled, each VLAN on this physical interface can send traffic only to the same VLAN. There is no cross-talk between VLANs, and ARP packets are forced to take one path along the network which prevents the multiple paths problem.

In the following example, `vlanforward` is disabled on port1. All VLANs configured on port1 will be separate and will not forward any traffic to each other.

```
config system interface
 edit port1
 set vlanforward disable
 end
```

## Forward-domain solution

If you are using transparent mode, the solution is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic. It is like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0. The many benefits of this solution include reduced administration, the need for fewer physical interfaces, and the availability of more flexible network solutions.

In the following example, forward-domain collision group 340 includes VLAN 340 traffic on port1 and untagged traffic on port 2. Forward-domain collision group 341 includes VLAN 341 traffic on port 1 and untagged traffic on port 3. All other interfaces are part of forward-domain collision group 0 by default. This configuration separates VLANs 340 and 341 from each other on port 1.

Use these CLI commands:

```
config system interface
 edit port2
 set forward_domain 340
```

```
next
edit port3
 set forward_domain 341
next
edit port1-340
 set forward_domain 340
 set interface port1
 set vlanid 340
next
edit port1-341
 set forward_domain 341
 set interface port1
 set vlanid 341
end
```

You may experience connection issues with layer-2 traffic, such as ping, if your network configuration has:

- Packets going through the FortiGate unit in transparent mode more than once
- More than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled

Now IPS and AV is applied the first time packets go through the FortiGate unit, but not on subsequent passes. Applying IPS and AV only to this first pass fixes the network layer-2 related connection issues.

### Asymmetric routing

You might discover unexpectedly that hosts on some networks are unable to reach certain other networks. This occurs when request and response packets follow different paths. If the FortiGate unit recognizes the response packets, but not the requests, it blocks the packets as invalid. Also, if the FortiGate unit recognizes the same packets repeated on multiple interfaces, it blocks the session as a potential attack.

This is asymmetric routing. By default, the FortiGate unit blocks packets or drops the session when this happens. You can configure the FortiGate unit to permit asymmetric routing by using the following CLI commands:

```
config system settings
 set asymroute enable
end
```

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem as follows:

```
config vdom
 edit <vdom_name>
 config system settings
 set asymroute enable
 end
 end
end
```

If this solves your blocked traffic issue, you know that asymmetric routing is the cause. But allowing asymmetric routing is not the best solution, because it reduces the security of your network.

For a long-term solution, it is better to change your routing configuration or change how your FortiGate unit connects to your network.

If you enable asymmetric routing, antivirus and intrusion prevention systems will not be effective. Your FortiGate unit will be unaware of connections and treat each packet individually. It will become a stateless firewall.

## Configuring IPv4 and IPv6 ICMP traffic inspection

In order for the inspection of asymmetric ICMP traffic not to affect TCP and UDP traffic, you can enable or disable ICMP traffic inspection for traffic being routed asymmetrically for both IPv4 and IPv6.

To configure ICMP traffic inspection, use the following CLI commands:

- IPv4:

```
config system settings
 set asymroute-icmp
end
```

- IPv6:

```
config system settings
 set asymroute6-icmp
end
```

## NetBIOS

Computers running Microsoft Windows operating systems that are connected through a network rely on a WINS server to resolve host names to IP addresses. The hosts communicate with the WINS server by using the NetBIOS protocol.

To support this type of network, you need to enable the forwarding of NetBIOS requests to a WINS server. The following example will forward NetBIOS requests on the internal interface for the WINS server located at an IP address of 192.168.111.222.

```
config system interface
 edit internal
 set netbios_forward enable
 set wins-ip 192.168.111.222
 end
```

These commands apply only in NAT mode. If VDOMs are enabled, these commands are per VDOM. You must set them for each VDOM that has the problem.

## Too many VLAN interfaces

Any virtual domain can have a maximum of 255 interfaces in transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. NAT mode supports from 255 to 8192 depending on the FortiGate model. This total number of interfaces includes VLANs, other virtual interfaces, and physical interfaces.

Your FortiGate unit may allow you to configure more interfaces than this. However, if you configure more than 255 interfaces, your system will become unstable and, over time, will not work properly. As all interfaces are used, they will overflow the routing table that stores the interface information, and connections will fail. When you try to add more interfaces, an error message will state that the maximum limit has already been reached.

If you see this error message, chances are you already have too many VLANs on your system and your routing has become unstable. To verify, delete a VLAN and try to add it back. If you have too many, you will not be able to add it back on to the system. In this case, you will need to remove enough interfaces (including VLANs) so that

the total number of interfaces drops to 255 or less. After doing this, you should also reboot your FortiGate unit to clean up its memory and buffers, or you will continue to experience unstable behavior.

To configure more than 255 interfaces on your FortiGate unit in transparent mode, you have to configure multiple VDOMs, each with many VLANs. However, if you want to create more than the default 10 VDOMs (or a maximum of 2550 interfaces), you must buy a license for additional VDOMs and your FortiGate must be able to be licensed for more than 10 VDOMs.

With these extra licenses, you can configure up to 500 VDOMs, with each VDOM containing up to 255 VLANs in transparent mode. This is a theoretical maximum of over 127 500 interfaces. However, system resources will quickly get used up before reaching that theoretical maximum. To achieve the maximum number of VDOMs, you need to have top-end hardware with the most resources possible.

In NAT mode, if you have a top-end model, the maximum interfaces per VDOM can be as high as 8192, which is enough for all the VLANs in your configuration.

Your FortiGate unit has limited resources, such as CPU load and memory, that are divided between all configured VDOMs. When running 250 or more VDOMs, you may need to monitor the system resources to ensure there is enough to support the configured traffic processing.

## Troubleshooting VLAN issues

Several problems can occur with your VLANs. Since VLANs are interfaces with IP addresses, they behave as interfaces and can have similar problems that you can diagnose with tools, such as ping, traceroute, packet sniffing, and diag debug.

## Botnet and command-and-control protection

You can configure botnet and command-and-control traffic protection, in the FortiGate GUI or CLI.

In the GUI, you can use select the **Scan Outgoing Connections to Botnet Sites** option on the **Interfaces** page. The options are **Disable**, **Block**, and **Monitor**.

In the CLI, you can configure the botnet scan on the interface, using the following commands:

```
config system interface
 edit <interface>
 set scan-botnet-connections [disable | block | monitor]
 end
```

You can also enable the scanning of botnet and command-and-control traffic in the following policies:

- Firewall policies:

```
config firewall policy
 edit <policyid>
 set scan-botnet-connections [disable | block | monitor]
 end
```

- Firewall explicit proxy policies:

```
config firewall explicit-proxy-policy
 edit <policyid>
 set scan-botnet-connections [disable | block | monitor]
```

```
end
```

- Firewall interface policy:

```
config firewall interface-policy
edit <policyid>
set scan-botnet-connections [disable | block | monitor]
end
```

- Firewall sniffer:

```
config firewall sniffer
edit <policyid>
set scan-botnet-connections [disable | block | monitor]
end
```

## DNS

A Domain Name System (DNS) server is a public service that converts symbolic node names to IP addresses. A DNS server implements the protocol. In simple terms, it acts as a phone book for the Internet. A DNS server matches domain names with their computer IP addresses. This allows you to use readable locations, such as `fortinet.com`, when you browse the Internet. FortiOS supports DNS configuration for both IPv4 and IPv6 addressing.

FortiGate includes default DNS server addresses. However, you should change these addresses to ones that your Internet Service Provider (ISP) provides. The defaults are DNS proxies and are not as reliable as those from your ISP.

Within FortiOS, there are two DNS configuration options. Each option provides a specific service and both options can work together to provide a complete DNS solution.

### DNS settings

You configure basic DNS queries on interfaces that connect to the Internet. When a user requests a website, FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

You configure DNS server addresses by selecting **Network > DNS**, and then specifying the DNS server addresses. These addresses are typically supplied by your ISP. If you have local Microsoft domains on the network, you can enter a domain name in the **Local Domain Name** field.

In a situation where all three fields are configured, FortiGate first looks to the local domain. If no match is found, FortiGate sends a request to the external DNS servers.

If virtual domains (VDOM) are enabled, you create a DNS database in each VDOM. All of the interfaces in a VDOM share the DNS database in that VDOM.

### Additional DNS CLI configuration

Additional DNS configuration options are available in the CLI, using the `config system dns` command. Within this command, you can also set the following commands:

| Command                               | Description                                                                                                                                                                           |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dns-cache-limit</code>          | Set how many DNS entries are stored in the cache. Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information. |
| <code>dns-cache-ttl</code>            | Set how long entries remain in the cache, in seconds. Possible values are 60 to 86400 (default is 24 hours).                                                                          |
| <code>cache-notfound-responses</code> | When you enable this, any DNS requests that are returned with NOT FOUND can be stored in the cache.                                                                                   |
| <code>source-ip</code>                | Define a dedicated IP address for communications with the DNS server.                                                                                                                 |

## DDNS

If your ISP changes your external IP address on a regular basis, and you have a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. If you have a FortiGuard subscription, you can use FortiGuard as the DDNS server.

You can configure FortiGuard as the DDNS server, in the FortiGate GUI or CLI.

To configure FortiGuard as the DDNS server in the FortiGate GUI, select **Network > DNS** and enable **FortiGuard DDNS**. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

To configure FortiGuard as the DDNS server in the FortiGate CLI, use the following CLI commands:

```
config system fortiguard
 set ddns-server-ip
 set ddns-server-port
end
```

If you do not have a FortiGuard subscription or want to use a different DDNS server, you can configure DDNS in the CLI. You can configure a DDNS for each interface. Only the first configured port appears in the FortiGate GUI. Additional commands vary depending on the DDNS server you select. Use the following CLI commands:

```
config system ddns
 edit <DDNS_ID>
 set monitor-interface <external_interface>
 set ddns-server <ddns_server_selection>
end
```

## Configuring FortiGate to refresh DDNS IP addresses

You can configure FortiGate to refresh DDNS IP addresses. FortiGate periodically checks the DDNS server that is configured. Use the following CLI commands:

```
config system ddns
 edit <1>
 set ddns-server FortiGuardDDNS
 set use-public-ip enable
```

```
 set update-interval seconds
end
```

The possible values for update-interval are 60 to 2592000 seconds, and the default is 300 seconds.

## TLS support for DDNS updates

When cleartext is disabled, FortiGate uses the SSL connection to send and receive Dynamic DNS services (DDNS) updates.

To disable cleartext, use the following CLI commands:

```
config system ddns
 set clear-text disable
end
```

The ssl-certificate name can also be set in the same location using the command:

```
set ssl-certificate <cert_name>
```

## DDNS update override for DHCP

DHCP server has an override command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the AA field every time, even if the DHCP client does not request it. This allows the support of the allow/ignore/deny client-updates options.

You can enable DDNS update override, using the following CLI commands:

```
config system dhcp server
 edit <0>
 set ddns-update_override enable
 end
```

## FortiDDNS registration to a public IP address

Fortinet's Dynamic DNS services (FortiDDNS) can be registered to a public IP address even if the FortiGate model does not have any physical interfaces on the Internet. This applies to when FortiGate is behind other networking devices that are employing NAT. You can configure this in the GUI and the CLI.

## DNS servers

You can also create local DNS servers for your network. Depending on your requirements, you can manually maintain your entries (master DNS server) or use it as a jumping point, where the server refers to an outside source (slave DNS server). A local master DNS server works similarly to the DNS server addresses configured in **Network > DNS**, but you must manually add all entries. This allows you to add a local DNS server to include specific URL and IP address combinations.

The DNS server options are not visible in the FortiGate GUI, by default. To enable the server, select **System > Feature Visibility**, select **DNS Database**, and select **Apply**.

While a master DNS server is an easy method to include regularly used addresses to save on going to an outside DNS server, it is not recommended to make it the authoritative DNS server. IP addresses may change and maintaining any type of list can become labor-intensive.

It is best to use a FortiGate master DNS server for local services. For example, a company has a web server in their DMZ that internal users (employees) and external users (customers or remote employees) access. When internal users access a website, a request for the website is sent out to the DNS server on the Internet, which

then returns an IP address or virtual IP address. After the company configures an internal DNS server, the same website request is resolved internally to the internal web server IP address. This minimizes inbound and outbound traffic, and access time.

As a slave DNS server, FortiGate refers to an external or alternate source as a way to obtain the URL and IP address combination. This is useful if there is a master DNS server for a large company, where a list is maintained. Satellite offices can then connect to the master DNS server to obtain the correct addressing.

The DNS server entries do not allow CNAME entries, as per [RFC 1912](#), section 2.4.

### Configure a master DNS server - web-based manager

1. Select **Network > DNS Servers**, and select **Create New** for **DNS Database**.
2. Select the **Type** of **Master**.
3. Select the **View** as **Shadow**.
4. The view is the accessibility of the DNS server. Selecting **Public**, external users can access, or use, the DNS server. Selecting **Shadow**, only internal users can use it.
5. Enter the DNS **Zone**, for example, `WebServer`.
6. Enter the domain name for the zone, for example `example.com`.
7. Enter the hostname of the DNS server, for example, `Corporate`.
8. Enter the contact address for the administrator, for example, `admin@example.com`.
9. Set **Authoritative** to **Disable**.
10. Select **OK**.
11. Enter the DNS entries for the server by selecting **Create New**.
12. Select the **Type**, for example, **Address (A)**.
13. Enter the **Hostname**, for example `web.example.com`.
14. Enter the remaining information, which varies depending on the **Type** selected.
15. Select **OK**.

### Configure a master DNS server - CLI

```
config system dns-database
 edit WebServer
 set domain example.com
 set type master
 set view shadow
 set ttl 86400
 set primary-name corporate
 set contact admin@example.com
 set authoritative disable
 config dns-entry
 edit 1
 set hostname web.example.com
 set type A
 set ip 192.168.21.12
 set status enable
 end
 end
 end
```

## Configuring a recursive DNS

You can set an option to ensure this type of DNS server is not the authoritative server. When configured, the FortiGate unit will check its internal DNS server (master or slave). If the request cannot be fulfilled, it will look to the external DNS servers. This is known as a split DNS configuration.

You can also have FortiGate look to an internal server if the master or slave does not fulfill the request, using the following CLI commands:

```
config system dns-database
 edit example.com
 ...
 set view shadow
 end
```

For this behavior to work completely, you must set the DNS query for the external interface to be recursive.

### Configure a recursive DNS - web-based manager

1. Go to **Network > DNS Servers**, and select **Create New** for **DNS Service on Interface**.
2. Select the **Interface**.
3. Select the **Mode** to **Recursive**.
4. Select **OK**.

### Configure a recursive DNS - CLI

```
config system dns-server
 edit wan1
 set mode recursive
 end
```

## Configuring IPv6 Router Advertisement options for DNS configuration

FortiGate supports the following RFC 6106 IPv6 Router Advertisement options:

- Obtaining DNS search list options from upstream DHCPv6 servers
- Sending the DNS search list through Router Advertisement
- Sending the DNS search list through the FortiGate DHCP server
- Sending DNS search list option to downstream clients with Router Advertisements that use a static prefix (FortiOS version 5.6.1 and later)
- Sending recursive DNS server option to downstream clients with Router Advertisements that use a static prefix (FortiOS version 5.6.1 and later)

### Obtain the DNS search list options from upstream DHCPv6 servers - CLI

```
config system interface
 edit wan1
 config ipv6
 set dhcp6-prefix-delegation enable
 next
 next
end
```

**Send DNS search lists through Router Advertisement - CLI**

```
config system interface
edit port 1
config IPv6
set ip6-address 2001:10::/64
set ip6-mode static
set ip6-send-adv enable
config ip6-delegated-prefix-list
edit 1
set upstream-interface WAN
set subnet 0:0:0:11::/64
set autonomous-flag enable
set onlink-flag enable
next
next
end
end
```

**Send the DNS search lists through the FortiGate DHCP server - CLI**

You can use the `dns-search-list delegated` command to send DNS search list option to downstream clients with Router Advertisements that use a static prefix, using the following CLI commands:

```
config system dhcp6 server
edit 1
set interface port2
set upstream-interface WAN
set ip-mode delegated
set dns-service delegated
set dns-search-list delegated
set subnet 0:0:0:12::/64
next
end
```

**Send DNS search list option to downstream clients with Router Advertisements that use a static prefix - CLI**

In FortiOS 5.6.1 and later, you can use the `set dnssl <DNS search list option>` command to send DNS search list option to downstream clients with Router Advertisements that use a static prefix, using the following CLI commands:

```
config system interface
edit port1
config ipv6
config ip6-prefix-list
edit <2001:db8::/64>
set autonomous-flag enable
set onlink-flag enable
set rdns 2001:1470:8000::66 2001:1470:8000::72
set dnssl <DNS search list option>
end
```

## Send recursive DNS server option to downstream clients with Router Advertisements that use a static prefix - CLI

In FortiOS 5.6.1 and later, you can use the `set rdNSS <recursive DNS search option>` command to send Recursive DNS server option to downstream clients with Router Advertisements that use a static prefix, using the following CLI commands:

```
config system interface
 edit port1
 config ipv6
 config ip6-prefix-list
 edit <2001:db8::/64>
 set autonomous-flag enable
 set onlink-flag enable
 set rdNSS 2001:1470:8000::66 2001:1470:8000::72
 set dnSSL <DNS search list option>
 end
 end
 end
 end
```

## Viewing the Internet Service Database

The Internet Service Database in the FortiGate GUI contains detailed information about services that are available on the Internet, such as DNS servers that Adobe, Google, Fortinet, and Apple provide. For each service, the database shows the IP addresses of the servers that host the service, and the port and protocol number that each IP address uses. To view the Internet Service Database, select **Policy & Objects > Internet Service Database** in the FortiGate GUI.

## Advanced static routing

Advanced static routing includes features and concepts that are used in more complex networks.

### Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

#### Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled, you will need to perform the following steps in addition to the procedure's steps.

#### To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

#### To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
 edit root
```

Following these commands, you can enter any routing CLI commands, as normal.

### Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

### Adding a static route

1. To add or edit a static route, go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

|                                |                                                                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Destination IP/Mask</b>     | Enter the destination IP address and netmask.<br>A value of 0 . 0 . 0 . 0 / 0 . 0 . 0 . 0 is universal.                                                                                                                                                    |
| <b>Gateway</b>                 | Enter the gateway IP address.                                                                                                                                                                                                                              |
| <b>Interface</b>               | Select the name of the interface that the static route will connect through.                                                                                                                                                                               |
| <b>Administrative Distance</b> | Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.                                                                                              |
| <b>Advanced Options</b>        | Optionally, expand <b>Advanced Options</b> and enter a <b>Priority</b> , which will artificially weight the route during route selection. The higher the priority number, the less likely the route is to be selected over other routes. The default is 0. |

## Enabling or disabling individual static routes

You can enable or disable individual static routes.

To configure IPv4 static routes, use the following CLI commands:

```
config route static
edit 0
set status [enable|disable]
end
```

To configure IPv6 static routes, use the following CLI commands:

```
config route static6
edit 0
set status [enable|disable]
end
```

## Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the **Static Route Configuration** option. Then, when configuring the static route, set **Destination** to **Named Address**.

In the CLI, use the following CLI commands:

First, configure the firewall FQDN address:

```
config firewall address
edit 'Fortinet-Documentation-Website'
set type fqdn
set fqdn docs.fortinet.com
set allow-routing enable
end
```

Next, add the FQDN address to a static route.

```
config router static
edit 0
```

```

set dstaddr Fortinet-Documentation-Website
...
end

```

## Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address, where you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people, where the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers lose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes, such as these, happen along a static route, traffic can no longer reach the destination and the route goes down. Dynamic routing can address these changes to ensure that traffic still reaches its destination. The process of realizing there is a problem, backtracking, and finding a route that is operational, is called convergence. If there is fast convergence in a network, users will not even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that are not used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes, which are the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information but it also looks up the source information to ensure that it exists. If there is no source to be found, that packet is dropped because the router assumes it is an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that are not used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes, which are the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

## Viewing the routing table

You can view the routing table in the FortiGate GUI. By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to **Monitor > Routing Monitor**. Select **Static & Dynamic** to view the routes.

You can also monitor policy routes. Select **Policy** to list the active policy routes on the FortiGate and see information about them. The active policy routes include policy routes that you create, SD-WAN rules, and Internet service static routes. It also supports downstream devices in the Security Fabric.

The following figure show an example of the static and dynamic routes in the Routing Monitor list.

| Refresh    | Route Lookup | Edit Route      | Create Address | Static & Dynamic Policy |          |
|------------|--------------|-----------------|----------------|-------------------------|----------|
| IP Version | Type         | Network         | Gateway IP     | Interfaces              | Distance |
| 4          | Static       | 0.0.0.0/0       | 172.25.176.1   | port1                   | 10       |
| 4          | Connected    | 172.25.176.0/24 | 0.0.0.0        | port1                   | 0        |
| 6          | Connected    | ::1/128         | ::             | root                    | 0        |
| 6          | System       | ff00::/8        | ::             | port3                   | 0        |

The following figure show an example of the policy routes in the Routing Monitor list.

| Refresh    | Edit Route | Static & Dynamic Policy  |     |                 |              |          |        |
|------------|------------|--------------------------|-----|-----------------|--------------|----------|--------|
| IP Version | From       | Source                   | To  | Destination     | Gateway IP   | Protocol | Action |
| 4          | mgmt1      | 10.10.10.0/255.255.255.0 | Any | 0.0.0.0/0.0.0.0 | 172.20.121.2 | Any      | Route  |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IP Version</b> | Shows whether the route is IPv4 or IPv6.<br><br>IPv6 routes are displayed only if IPv6 is enabled in the FortiGate GUI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Type</b>       | <p>The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP).</p> <ul style="list-style-type: none"> <li><b>All:</b> all routes recorded in the routing table</li> <li><b>Connected:</b> all routes associated with direct connections to FortiGate unit interfaces</li> <li><b>Static:</b> the static routes that have been added to the routing table manually</li> <li><b>RIP:</b> all routes learned through RIP. For more information, see <a href="#">RIP on page 2519</a></li> <li><b>RIPNG:</b> all routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks)</li> <li><b>BGP:</b> all routes learned through BGP. For more information, see <a href="#">BGP on page 2598</a>.</li> <li><b>OSPF:</b> all routes learned through OSPF. For more information, see <a href="#">OSPF on page 2557</a>.</li> <li><b>OSPF6:</b> all routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks)</li> <li><b>IS-IS:</b> all routes learned through IS-IS. For more information, see <a href="#">IS-IS on page 2637</a>.</li> <li><b>HA:</b> RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster.</li> </ul> <p>For more information about HA routing synchronization, see the <a href="#">FortiGate HA User Guide</a>.</p> |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Subtype</b>    | <p>If applicable, the subtype classification assigned to OSPF routes.</p> <p>An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected.</p> <ul style="list-style-type: none"> <li>• <b>OSPF inter area:</b> the destination is in the OSPF AS, but FortiGate is not connected to that area.</li> <li>• <b>External 1:</b> the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.</li> <li>• <b>External 2:</b> the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost.</li> <li>• <b>OSPF NSSA 1:</b> same as External 1, but the route was received through a not-so-stubby area (NSSA)</li> <li>• <b>OSPF NSSA 2:</b> same as External 2, but the route was received through a not-so-stubby area</li> </ul> <p>For more information about OSPF subtypes, see <a href="#">OSPF on page 2557</a>.</p> |
| <b>Network</b>    | The IP addresses and network masks of destination networks that FortiGate can reach.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Gateway IP</b> | The IP addresses of gateways to the destination networks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Interfaces</b> | The interface through which packets are forwarded to the gateway of the destination network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Up Time</b>    | The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Distance</b>   | <p>The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate unit may routinely use the route to communicate with neighboring routers and access servers.</p> <p>Modifying this distance for dynamic routes is route distribution. See <a href="#">BGP on page 2598</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b> | <p>The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to.</p> <p><b>Hop count:</b> routes learned through RIP</p> <p><b>Relative cost:</b> routes learned through OSPF</p> <p><b>Multi-Exit Discriminator (MED):</b> routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see <a href="#">BGP on page 2598</a>. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column will display a non-zero value.</p> <p>Not displayed when IP version 6 is selected.</p> |

### Copying DSCP value in GRE tunnels

You can enable an option to allow copying of the DSCP (Differentiated services code point) value in GRE tunnels. This feature enables the keeping of the DSCP marking in the packets after encapsulation for going through GRE tunnels.

To enable DSCP copying, use the following CLI commands:

```
config sys gre-tunnel
 set dscp-copying enable
```

### Configuring the maximum number of IP route cache entries

You can configure the maximum number of route cache entries, using the following CLI commands:

```
config system global
 set max-route-cache-size <integer between 0 - 2147483647>
end
```

Unsetting the field causes the value to be set to the kernel calculated default:

```
config system global
 unset max-route-cache-size
end
```

### Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get router static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed, including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

### To view the routing table

```
get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2

C 192.168.182.0/23 is directly connected, port2
```

### Examining an entry:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

| Value                | Description                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>B</b>             | BGP. The routing protocol used.                                                                                                                 |
| <b>10.160.0.0/23</b> | The destination of this route, including netmask.                                                                                               |
| <b>[20/0]</b>        | 20 indicates administrative distance of 20 out of a range of 0 to 255.<br>0 is an additional metric associated with this route, such as in OSPF |
| <b>10.142.0.74</b>   | The gateway, or next hop.                                                                                                                       |
| <b>port3</b>         | The interface used by this route.                                                                                                               |
| <b>2d18h02m</b>      | How old this route is. In this case, it is almost three days old.                                                                               |

### To view the kernel routing table

```
get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->10.11.201.0/24
 pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0->172.20.120.0/24
 pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

| Value                                                    | Description                                                                                                                                                                                                                              |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tab</b>                                               | Table number. This will be either 254 (unicast) or 255 (multicast).                                                                                                                                                                      |
| <b>vf</b>                                                | Virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.                                                                                                                          |
| <b>type</b>                                              | Type of routing connection. Valid values include:<br><br>0 - unspecified<br>1 - unicast<br>2 - local<br>3 - broadcast<br>4 - anycast<br>5 - multicast<br>6 - blackhole<br>7 - unreachable<br>8 - prohibited                              |
| <b>proto</b>                                             | Type of installation. This indicates where the route came from. Valid values include:<br><br>0 - unspecified<br>2 - kernel<br>11 - ZebOS routing module<br>14 - FortiOS<br>15 - HA<br>16 - authentication based<br>17 - HA1              |
| <b>prio</b>                                              | Priority of the route. Lower priorities are preferred.                                                                                                                                                                                   |
| <b>-&gt;10.11.201.0/24</b><br><b>(-&gt;x.x.x.x/mask)</b> | The IP address and subnet mask of the destination                                                                                                                                                                                        |
| <b>pref</b>                                              | Preferred next hop along this route                                                                                                                                                                                                      |
| <b>gwy</b>                                               | Gateway - the address of the gateway this route will use                                                                                                                                                                                 |
| <b>dev</b>                                               | Outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface, it will also be displayed here. |

## Searching the routing table

You can apply a filter to search the routing table and display only certain routes. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed. An implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select **Connected** from the **Type** list, type 172.16.14.0/24 in the **Network** field, and then select **Apply Filter** to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its **Type** field and the specified value in the **Gateway** field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24.

### To search the FortiGate unit routing table - web-based manager

1. Go to **Monitor > Routing Monitor**.
2. From the **Type** list, select the type of route to display. In our example, select **Static**.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the **Networks** field. In our example, enter 10.10.10.10/24.
4. If you want to display routes to a specific gateway, type the IP address of the gateway in the **Gateway** field.
5. Select **Apply Filter**.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

### To search the FortiGate unit routing table - CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
 Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed and the best match will be at the top of the list and indicated by the word best.

## Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination—the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the

closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit's forwarding table, which is a subset of the unit's routing table. Packets are forwarded according to the information in the forwarding table.

## Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers can steal not only your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

## Network Address Translation

Network address translation (NAT) is a method of changing the address from which traffic appears to originate. This practice is used to hide the IP address on a company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network, as would be the case without NAT. Securing the network is much cheaper and easier to maintain.

Configuring NAT on your FortiGate unit includes the following steps:

1. Configure your internal network. For example, use the `10.11.101.0` subnet.
2. Connect your internal subnet to an interface on your FortiGate unit. For example, use `port1`.
3. Connect your external connection (for example, an ISP gateway of `172.20.120.2`) to another interface on your FortiGate unit (for example, `port2`).

Configure security policies to allow traffic between `port1` and `port2` on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the `10.11.101.0` subnet and pass on to the `172.20.120.0` network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet and it does not appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the FortiGate unit, but they will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However, other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider can access

only the FortiGate unit's external interface, unless the security policy allows the traffic through to the internal network. If allowed in, the correct internal user would respond to the chat. However, if it is not allowed, the request to chat will be refused or it will time out. This is accomplished in the security policy by allowing or denying different protocols.

### Access control list

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router checks the ACL to see if that traffic is allowed over that port. If it is allowed on that incoming interface, the next step is to check the ACL for the destination interface. If the traffic also passes that check, the buffered traffic is delivered to its destination. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective, the ACL must be kept up to date. When employees or computers are removed from the internal network, their IP addresses must also be removed from the ACL. For more information about the ACL, see the router chapter of the [FortiGate CLI Reference](#).

### Blackhole routes

A blackhole route is a route that drops all traffic sent to it. It is very much like `/dev/null` in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses, which may be valid or malicious, can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, which is a virtual interface that does not forward traffic, was added to allow easier configuration of blackhole routing. Similar to a regular interface, the loopback interface has fewer parameters to configure and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the [FortiGate CLI Reference](#).

### Configuring IPv6 blackhole routes

You can configure IPv6 blackhole routes. In the FortiGate GUI, select **Network > Static Routes** and select **Create New**. In the **Interface** field, choose **Blackhole**.

New Static Route

Destination IP/Mask:

Interface:

Administrative Distance:

Comments:  0/255

Status: ☒ Enabled ☐ Disabled

### Adding a blackhole route with a priority

You can add a priority to a blackhole route to change its position relative to kernel routes in the routing table.

To add a blackhole route with a priority, use the following CLI commands:

```
config router static
 edit 23
 set blackhole enable
 set priority 200
 end
```

### IPv6 blackhole static routing

System administrators use blackhole routing to divert unwanted traffic, such as packets from a Denial of Service (DoS) attack or communications from an illegal source. The traffic is routed to a dead interface, or a host designed to collect information for investigation. This mitigates the impact of the attack on the network.

You can enable the use of blackhole routing, using the following CLI commands:

```
config router static6
 edit <ID #>
 set blackhole enable
 end
```

### Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address, and the local configuration permits delivery, the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the FortiGate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

### Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance

can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works. If there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available), the traffic will use the route with an administrative distance of 5. If for some reason the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. The default administrative distances for any of these routing protocols are configurable.

### Default administrative distances for routing protocols and connections

| Routing protocol           | Default administrative distance |
|----------------------------|---------------------------------|
| Direct physical connection | 1                               |
| Static                     | 10                              |
| EBGP                       | 20                              |
| OSPF                       | 110                             |
| IS-IS                      | 115                             |
| RIP                        | 120                             |
| IBGP                       | 200                             |

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route can be set in the CLI, or when editing a specific static route, as described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes that have the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols, such as RIP, can use metrics that are similar to administrative distance.

### Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

**To change the priority of a route - web-based manager**

1. Go to **Network > Static Routes**.
2. Select the route entry, and select **Edit**.
3. Select **Advanced Options**.
4. Enter the **Priority** value.
5. Select **OK**.

**To change the priority of a route - CLI**

The following command changes the priority to 5 for a route to the address 10.10.10.1 on the port1 interface.

```
config router static
edit 1
 set device port1
 set gateway 10.10.10.10
 set dst 10.10.10.1
 set priority 5
end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal-cost multi-path (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, different sessions will resolve this problem by using different routes to the same address.

**Use of firewall addresses for static route destinations**

To help prevent false positive when scanning for duplicate static routes, the `dst_addr` field is also checked.

**Removing RPF checks from the state evaluation process**

You can remove RPF (reverse path forwarding) state checks without needing to enable asymmetric routing. You can disable state checks for traffic received on specific interfaces.

Disabling state checks makes a FortiGate unit less secure and should only be done with caution.

---

To remove RPF checks from the state evaluation process, use the following CLI commands:

```
config system interface
edit <interface_name>
 set src-check disable
end
```

## Troubleshooting static routing

When there are problems with your network that you believe to be related to static routing, there are a few basic tools available to locate the problem.

These tools include:

- [Ping](#)
- [Traceroute](#)
- [Examine routing table contents](#)

### Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- Possible ECMP, split horizon, network loops
- Cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- Hardware: ensure cabling is correct, and all equipment between the two locations is accounted for
- Addresses and routes: ensure all IP addresses and routing information along the route is configured as expected
- Firewalls: ensure all firewalls are set to allow PING to pass through

### To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

### To ping from an Apple computer

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

### To ping from a Linux PC

1. Go to a command line prompt.
2. Enter `"/bin/etc/ping 10.11.101.101"`.

### Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

### To use traceroute on a Windows PC

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter “cmd” and select **OK**.
2. Enter “tracert fortinet.com” to trace the route from the PC to the Fortinet website.

### To use traceroute from an Apple computer

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

### To use traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter “`/bin/etc/traceroute fortinet.com`”.

The Linux traceroute output is very similar to the MS Windows traceroute output.

### Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route is not used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you will not be able to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor. Go to **Monitor > Routing Monitor**. In the CLI, use the command `get router info routing-table all`.

## Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

### Always configure a default route

The first thing you configure on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there is an outage on the network it will either be very localized or network-wide. Either outage is easy to troubleshoot.

### Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially, it puts all your resources on the network and shows how the parts of your network are connected. Keeping your plan updated will also help you

troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks and helping troubleshoot any routing problems that come up. Also, you can use it to plan for the future and act on any changes to your needs or resources more quickly.

### Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example, allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing and to troubleshoot any problems.

### Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step
- Implement black hole routing to hide which IP addresses are in use or not on your local network
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network

All three features limit access to the people who should be using your network and obscure your network information from the outside world and potential hackers.

## Policy routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional, and a matching policy alone might not provide enough information for forwarding the packet. In fact, the FortiGate almost always requires a matching route in the routing table in order to use a policy route. The FortiGate unit will refer to the routing table in an attempt to match the information in the packet header with a route in the routing table.

---

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to **Network > Policy Routes**.

| Field              | Description                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Create New</b>  | Add a policy route. See <a href="#">Adding a policy route on page 2490</a> .                                                                                    |
| <b>Edit</b>        | Edit the selected policy route.                                                                                                                                 |
| <b>Delete</b>      | Delete the selected policy route.                                                                                                                               |
| <b>Move To</b>     | Move the selected policy route. Enter the new position and select <b>OK</b> .<br>For more information, see <a href="#">Moving a policy route on page 2493</a> . |
| <b>#</b>           | The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.                                     |
| <b>Incoming</b>    | The interfaces on which packets subjected to route policies are received.                                                                                       |
| <b>Outgoing</b>    | The interfaces through which policy routed packets are routed.                                                                                                  |
| <b>Source</b>      | The IP source addresses and network masks that cause policy routing to occur.                                                                                   |
| <b>Destination</b> | The IP destination addresses and network masks that cause policy routing to occur.                                                                              |

### Adding a policy route

To add a policy route, go to **Network > Policy Routes** and select **Create New**.

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Protocol</b>              | Select from existing or specify the protocol number to match. The Internet Protocol Number is found in the IP packet header. <a href="#">RFC 5237</a> describes protocol numbers and you can find a list of the assigned protocol numbers <a href="#">here</a> . The range is from 0 to 255. A value of 0 disables the feature.<br><br>Commonly used <b>Protocol</b> settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions. |
| <b>Incoming Interface</b>    | Select the name of the interface through which incoming packets subjected to the policy are received.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Source Address / Mask</b> | To perform policy routing based on IP source address, type the source address and network mask to match. A value of 0.0.0.0/0.0.0.0 disables the feature.                                                                                                                                                                                                                                                                                                                                               |

| Field                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Destination Address / Mask</b> | To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of 0.0.0.0/0.0.0.0 disables the feature.                                                                                                                                                                                                                                                                  |
| <b>Destination Ports</b>          | <p>To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature.</p> <p>The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.</p> |
| <b>Type of Service</b>            | Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see <a href="#">Type of Service on page 2492</a> .                                                                                                                                                                                                                                                            |
| <b>Outgoing Interface</b>         | Select the name of the interface through which packets affected by the policy will be routed.                                                                                                                                                                                                                                                                                                                                                          |
| <b>Gateway Address</b>            | Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.                                                                                                                                                                                                                                                                                                                                         |

### Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic, set protocol to 6 (for TCP) and set both of the destination ports to 21 (the FTP port).

| Field                             | Value                                    |
|-----------------------------------|------------------------------------------|
| <b>Protocol</b>                   | 6                                        |
| <b>Incoming interface</b>         | port1                                    |
| <b>Source address / mask</b>      | 0.0.0.0/0.0.0.0                          |
| <b>Destination address / mask</b> | 0.0.0.0/0.0.0.0                          |
| <b>Destination Ports</b>          | From 21 to 21                            |
| <b>Type of Service</b>            | bit pattern: 00 (hex) bit mask: 00 (hex) |
| <b>Outgoing interface</b>         | port10                                   |
| <b>Gateway Address</b>            | 172.20.120.23                            |

### Enabling or disabling individual policy routes

You can enable or disable individual policy routes.

To configure IPv4 policy routes, use the following CLI commands:

```
config router policy
edit 0
set status [enable|disable]
end
```

To configure IPv6 policy routes, use the following CLI commands:

```
config router policy6
edit 0
set status [enable|disable]
end
```

## Type of Service

Type of service (TOS) is an 8-bit field in the IP header that allows you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see [RFC 791](#) and [RFC 1349](#).

### The role of each bit in the IP header TOS 8-bit field

| Bit          | Quality                        | Description                                                                                                                                                                                                      |
|--------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bits 0, 1, 2 | <b>Precedence</b>              | Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits. |
| bit 3        | <b>Delay</b>                   | When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.                                                               |
| bit 4        | <b>Throughput</b>              | When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth, such as video conferencing.                                                         |
| bit 5        | <b>Reliability</b>             | When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available, such as with DNS servers.                                                              |
| bit 6        | <b>Cost</b>                    | When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3, 4, or 5, and bit 6 indicates to use the lowest cost route.                  |
| bit 7        | <b>Reserved for future use</b> | Not used at this time.                                                                                                                                                                                           |

For example, if you want to assign low delay and high reliability for a VoIP application, where delays are unacceptable, you would use a bit pattern of xxx1x1xx where 'x' indicates that bit can be any value. Since all bits

are not set, this is a good use for the bit mask. If the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

## Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example 172.20.0.0/255.255.0.0 and 172.20.120.0/255.255.255.0. If both of these routes are in the policy table, both can match a route to 172.20.120.112 but you would consider the second one a better match. In that case, the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to **Network > Policy Routes** and select **Move To** for the policy route you want to move.

| Field                  | Description                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Before/After</b>    | Select Before to place the selected policy route before the indicated route. Select After to place it following the indicated route. |
| <b>Policy route ID</b> | Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.                         |

## Use of firewall addresses for policy route destinations

When you configure a policy route, you can use firewall addresses and address groups. The only exception for address types that can be used is the URL type of address object.

## Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT operating mode is the standard mode, where all interfaces are accessed individually and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge. Traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to **Network > Routing Table**.

When viewing or creating a static route entry in transparent mode, there are only three fields available.

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Destination IP / Mask</b> | <p>The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed.</p> <p>Use 0.0.0.0 to match all traffic destinations. This is the default route.</p>                                                                                                                                                                         |
| <b>Gateway</b>               | <p>Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.</p>                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Priority</b>              | <p>The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable, the other routes can be used instead.</p> <p>Valid range of priority can be from 0 to 4 294 967 295.</p> <p>If more than one route matches and they have the same priority, it becomes an ECMP situation and traffic is shared among those routes. See <a href="#">Transparent mode static routing on page 2493</a>.</p> |

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet, all static routing on the FortiGate unit will use that gateway. For this reason, static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT mode.

## Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dental office that includes a number of dentists, assistants, and office staff. The size of the office is not expected to grow significantly in the near future, and the network usage is very stable (there are no new applications being added to the network).

The users on the network are:

- Administrative staff: access to local patient records, and perform online billing
- Dentists: access and update local patient records, research online from desk
- Assistants: access and update local patient records in exam rooms

The distinction here is mainly that only the administrative staff and dental office need access to the Internet. All the other traffic is local and does not need to leave the local network. Routing is only required for the outbound traffic, and the computers that have valid outbound traffic.

Configuring routing only on computers that need it, acts as an additional layer of security by helping prevent malicious traffic from leaving the network.

## Network layout and assumptions

The computers on the network are administrative staff computers, dental office computers, and dental exam room computers. While there are other devices on the local network, such as printers, they do not need Internet access or any routing.

This networked office equipment includes 1 administrative staff PC, 3 dentist's PCs, and 5 exam room PCs. There is also a network printer and a router on the network.

Assumptions about these computers and network include:

- The FortiGate unit is a model with interfaces labeled port1 and port2.
- The FortiGate unit has been installed and is configured in NAT mode.
- VDOMs are not enabled.
- The computers on the network are running MS Windows software.
- Any hubs required in the network are not shown in the network diagram.
- The network administrator has access to the ISP IP addresses and is the super\_admin administrator on the FortiGate unit.

### Static routing example device names, IP addresses, and level of access

| Device name | IP address       | Need external access? |
|-------------|------------------|-----------------------|
| Router      | 192.168.10.1     | YES                   |
| Admin       | 192.168.10.11    | YES                   |
| Dentist1-3  | 192.168.10.21-23 | YES                   |
| Exam1-5     | 192.168.10.31-35 | NO                    |
| Printer     | 192.168.10.41    | NO                    |

## General configuration steps

The steps to configuring routing on this network are:

1. [Get your ISP information such as DNS, gateway, etc.](#)
2. [Configure FortiGate unit](#)
3. [Configure administrator PC and dentists' PCs](#)
4. [Testing network configuration](#)

### Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses needed for routing are your assigned IP address, DNS servers, and the gateway.

## Configure FortiGate unit

The FortiGate unit will have two interfaces in use: one connected to the internal network, and one connected to the external network. Port1 will be the internal interface and port2 will be the external interface.

To configure the FortiGate unit:

1. [Configure the internal interface \(port1\)](#)
2. [Configure the external interface \(port2\)](#)
3. [Configure networking information](#)
4. [Configure basic security policies](#)
5. [Configure static routing](#)

### Configure the internal interface (port1)

#### To configure the internal interface (port1) - web based manager

1. Go to **Network > Interfaces**. Highlight **port1** and select **Edit**.
2. Enter the following:

|                              |                           |
|------------------------------|---------------------------|
| <b>Addressing Mode</b>       | Manual                    |
| <b>IP/Netmask</b>            | 172.100.1.1/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS, PING, TELNET       |
| <b>Description</b>           | Internal network          |

#### To configure the internal interface (port1) - CLI

```
config system interface
 edit port1
 set IP 192.168.10.1 255.255.255.0
 set allowaccess https ping telnet
 set description "internal network"
 end
end
```

### Configure the external interface (port2)

The external interface connects to your ISP's network. You need to know the IP addresses in their network that you should connect to. In this example, the address that the ISP gave you is 172.100.20.20, which will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

#### To configure the internal interface (port2) - web based manager

1. Go to **Network > Interfaces**. Highlight **port2** and select **Edit**.
2. Enter the following:

|                        |        |
|------------------------|--------|
| <b>Addressing Mode</b> | Manual |
|------------------------|--------|

|                              |                             |
|------------------------------|-----------------------------|
| <b>IP/Netmask</b>            | 172.100.20.20/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS, PING, TELNET         |
| <b>Description</b>           | Internal network            |

### To configure the internal interface (port2) - CLI

```
configure system interface
edit port2
set IP 172.100.20.20 255.255.255.0
set allowaccess https ping telnet
set description "internal network"
end
end
```

### Configure networking information

Networking information includes the gateway and DNS servers. Your FortiGate unit requires a connection to the Internet for antivirus and other periodic updates.

### To configure networking information - web-based manager

1. Go to **Network > DNS**.
2. Enter the primary and secondary DNS addresses.
3. Select **Apply**.

### To configure networking information - CLI

```
config system global
set dns_1 172.11.22.33
set dns_2 172.11.22.34
end
```

### Configure basic security policies

For traffic to flow between the internal and external ports in both directions, as a minimum, two security policies are required. More can be used to further limit or direct traffic, as needed, but will not be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents a PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- Only the basic networking services have been listed as allowed, for added security. Others can easily be added as the users require them.
- In this example, to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users to update their software. The FortiGate unit can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

**To configure security policies - web-based manager**

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create a new Firewall Address entry for each of:

| PC Name  | IP Address    | Interface |
|----------|---------------|-----------|
| Admin    | 192.168.10.11 | port1     |
| Dentist1 | 192.168.10.21 | port1     |
| Dentist2 | 192.168.10.22 | port1     |
| Dentist3 | 192.168.10.23 | port1     |

3. Go to **Policy & Objects > Objects > Addresses**.
4. Select the dropdown arrow next to **Create New** and select **Address Group**.
5. Name the group Internet\_PCs.
6. Add Admin, Dentist1, Dentist2, and Dentist3 as members of the group.
7. Select **OK**.
8. Go to **Policy & Objects > Policy > IPv4**.
9. Select **Create New**.
10. Enter the following: DH - port2(external) -> port1(internal)

|                            |                                                                               |
|----------------------------|-------------------------------------------------------------------------------|
| <b>Incoming Interface</b>  | port2                                                                         |
| <b>Source Address</b>      | all                                                                           |
| <b>Outgoing Interface</b>  | port1                                                                         |
| <b>Destination Address</b> | Internet_PCs                                                                  |
| <b>Schedule</b>            | always                                                                        |
| <b>Service</b>             | Multiple.<br>Select <b>DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH</b> . |
| <b>Action</b>              | ACCEPT                                                                        |
| <b>Log Allowed Traffic</b> | Enabled                                                                       |

11. Select **OK**.
12. Select **Create New**.
13. Enter the following:

|                           |              |
|---------------------------|--------------|
| <b>Incoming Interface</b> | port1        |
| <b>Source Address</b>     | Internet_PCs |

|                            |                                                                              |
|----------------------------|------------------------------------------------------------------------------|
| <b>Outgoing Interface</b>  | port2                                                                        |
| <b>Destination Address</b> | all                                                                          |
| <b>Schedule</b>            | always                                                                       |
| <b>Service</b>             | Multiple.<br>Select <b>DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.</b> |
| <b>Action</b>              | ACCEPT                                                                       |
| <b>Log Allowed Traffic</b> | Enabled                                                                      |

14. Select **OK**.

### To configure security policies - CLI

```

config firewall address
 edit "Admin"
 set associated-interface "port1"
 set subnet 192.168.10.11 255.255.255.255
 next
 edit "Dentist1"
 set associated-interface "port1"
 set subnet 192.168.10.21 255.255.255.255
 next
 edit "Dentist2"
 set associated-interface "port1"
 set subnet 192.168.10.22 255.255.255.255
 next
 edit "Dentist3"
 set associated-interface "port1"
 set subnet 192.168.10.23 255.255.255.255
 end
config firewall addrgrp
 edit Internet_PCs
 set member Admin Dentist1 Dentist2 Dentist3
 end
config firewall policy
 edit 1
 set srcintf port1
 set dstintf port2
 set srcaddr Internet_PCs
 set dstaddr all
 set action accept
 set schedule always
 set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
 set logtraffic enable
 set label "Section2"
 set endpoint-restrict-check no-av db-outdated
 next
 edit 2
 set srcintf port2
 set dstintf port1

```

```
set srcaddr all
set dstaddr Internet_PCs
set action accept
set schedule always
set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
set logtraffic enable
set label "Section2"
set endpoint-restrict-check no-av db-outdated
end
end
```

## Adding FortiClient enforcement to interfaces

You can enforce the use of FortiClient on individual interfaces.

In the FortiGate GUI, select **Network > Interfaces** and choose an interface. Under the **Admission Control** heading, you can enable the **Allow FortiClient Connections** setting. Once you enable this setting, two more options become visible: **Discover Clients (Broadcast)** and **FortiClient Enforcement**. When you enable FortiClient enforcement, you enforce that in order for incoming traffic to pass through that interface, it must be initiated by a device running FortiClient.

Once you enforce the use of FortiClient on the interface, you should also configure FortiClient profiles for the incoming connections. You can also set up any exemptions that are needed. Just below the **FortiClient Enforcement** option are fields for **Exempt Sources** and **Exempt Destinations/Services**. These can be selected from address or services objects already configured on the FortiGate.

In the CLI, use the following commands:

```
config system interface
edit port1
set listen-forticlient-connection [enable|disable]
set endpoint-compliance [enable|disable]
end
```

## Configure static routing

With the rest of the FortiGate unit configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

### To configure Fortinet unit static routing - web-based manager

1. Go to **Network > Static Routes**.
2. Select the top route on the page and then select **Edit**.
3. Enter the following information:

|                                |              |
|--------------------------------|--------------|
| <b>Destination IP/Mask</b>     | 172.100.20.5 |
| <b>Gateway</b>                 | 172.100.20.5 |
| <b>Interface</b>               | port2        |
| <b>Administrative Distance</b> | 10           |

4. Select **OK**.

### To configure Fortinet unit static routing - CLI

```
configure routing static
edit 1
set gateway 172.100.20.5
set distance 10
set device port2
set dst 0.0.0.0
end
end
```

### Configure administrator PC and dentists' PCs

After the router is configured, we need to configure the computers that require Internet access. These computers need routing to be configured on them. As the other computers do not require routing, they are not included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure does not configure the DNS entries. It just adds the static routes.

### To configure routing and DNS on administrator and dentists' PCs - Windows GUI

1. On the PC, select **Start > Control Panel > Network Connections**.
2. Right click on the network connection to your local network that has a status of Connected, and select **Properties**.
3. Under the **General** tab, from the list select **TCP/IP**, and **Properties**.
4. Under **Gateway**, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select **OK**.

### To configure routing on administrator and dentists' PCs - Windows CLI

1. On the PC, select **Start > Run**, enter "cmd", and select **OK**.
2. At the command prompt, type:

```
route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
```

3. Confirm these routes have been added. Type:

```
route PRINT
```

If you do not see the two routes you added, try adding them again, while paying attention to avoid spelling mistakes.

4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate unit.

### Configure other PCs on the local network

The PCs on the local network without Internet access (for example, the exam room PCs) can be configured now.

As this step does not require any routing, details have not been included.

## Testing network configuration

There are three tests to run on the network to ensure proper connectivity:

- To test that PCs on the local network can communicate
- Test that Internet\_PCs on the local network can access the Internet
- Test that non-Internet\_PCs cannot access the Internet

### Test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt, enter `ping 192.168.10.23`.

The output from this command should appear similar to the following:

```
Pinging 192.168.10.23 with 32 bytes of data:
```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt, enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt, enter `ping 192.168.10.34`.

The output from this command should appear similar to the following:

```
Pinging 192.168.10.34 with 32 bytes of data:
```

```
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

```
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

```
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt, enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.

If the output does not appear similar to above, there is a problem with the network configuration between these two PCs.

### To test that Internet\_PCs on the local network can access the Internet

The easiest way to access the Internet is with an Internet browser. However, if that does not work, it is best to do a traceroute to see at what point the problem is. This can help determine if it is a networking problem such as cabling, or if it is an access problem, such as this PC not having Internet access.

1. Select any PC on the local network that is supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet, such as <http://www.fortinet.com>.

If this is successful, this PC has Internet access.

3. If step2 was not successful, at the command prompt on the PC, enter `tracert 22.11.22.33`.

The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:
```

```
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

```
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

```
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

## Dynamic routing overview

This section provides an overview of dynamic routing and how it compares to static routing.

### What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. Instead of having to manually enter static routes in the routing table, dynamic routing automatically receives routing updates and dynamically decides which routes are best to go into the routing table. It is this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information about these administrative distances, see [Advanced static routing on page 2473](#).

### Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages, for the routing to come together despite obstacles. For example, if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table. If a network administrator does not fix a routing problem manually, it may never be fixed and may result in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making process about the optimal route, and using the routing tables of these routers to find potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits includes more complexity and some overhead. For example, the routing protocol uses some bandwidth for its own administration.

### Comparing static and dynamic routing

| Feature                       | Static routing                    | Dynamic routing                                                |
|-------------------------------|-----------------------------------|----------------------------------------------------------------|
| <b>Hardware support</b>       | Supported by all routing hardware | May require special, more expensive routers                    |
| <b>Router memory required</b> | Minimal                           | Can require considerable memory for larger tables              |
| <b>Complexity</b>             | Simple                            | Complex                                                        |
| <b>Overhead</b>               | None                              | Varying amounts of bandwidth used for routing protocol updates |
| <b>Scalability</b>            | Limited to small networks         | Very scalable, better for larger networks                      |

| Feature            | Static routing                                      | Dynamic routing                                      |
|--------------------|-----------------------------------------------------|------------------------------------------------------|
| <b>Robustness</b>  | None: if a route fails, it has to be fixed manually | Robust: traffic routed around failures automatically |
| <b>Convergence</b> | None                                                | Varies from good to excellent                        |

## Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route), support. Typically, the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example, RIP and BGP use distance vector algorithms and OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses. One protocol may have fast convergence, while another may be very reliable, and a third may be very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- [Classful versus classless routing protocols](#)
- [Interior versus exterior routing protocols](#)
- [Distance vector versus link-state protocols](#)

## Classful versus classless routing protocols

Classful and classless routing refers to how the routing protocol handles the IP addresses. In classful addresses, there is the specific address and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with [RFC 1519](#) and most recently with [RFC 4632](#)) to keep routing tables from getting too large. With classful routing, each IP address requires its own entry in the routing table. With classless routing, a series of addresses can be combined into one entry, potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing, out of necessity, include RIPv2, BGP, IS-IS, and OSPF. Older protocols, such as RIPv1, do not support CIDR addresses.

## Interior versus exterior routing protocols

The names interior and exterior are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol. This prevents them from connecting outside the network without passing through the border. Exterior routers in such a configuration must have both exterior and interior protocols to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to exterior routing protocols.

## Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route: distance vector and link-state.

### Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination and, in more advanced routing protocols, these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, [RFC 1058](#), which defines RIP v1, states the following:

*Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information; in other words, it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed forever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops, however, so this weakness is not as serious as it may first appear.

### Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along information only about the networks and devices that are directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

## Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on the FortiGate unit, and one other router configured as well. Some protocols require larger networks to function as designed.

**Minimum configuration based on dynamic protocol**

|                  | BGP                | RIP          | OSPF / IS-IS |
|------------------|--------------------|--------------|--------------|
| <b>Interface</b> | Yes                | Yes          | Yes          |
| <b>Network</b>   | Yes                | Yes          | Yes          |
| <b>AS</b>        | Local and neighbor | No           | Yes          |
| <b>Neighbors</b> | At least one       | At least one | At least one |
| <b>Version</b>   | No                 | Yes          | No           |
| <b>Router ID</b> | No                 | No           | Yes          |

**Comparison of dynamic routing protocols**

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

**Features of dynamic routing protocols**

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information about these dynamic routing protocols, see [RIP on page 2519](#), [BGP on page 2598](#), [OSPF on page 2557](#), and [IS-IS on page 2637](#).

**Comparing RIP, BGP, and OSPF dynamic routing protocols**

| Protocol                 | RIP                         | BGP                                                   | OSPF / IS-IS                                 |
|--------------------------|-----------------------------|-------------------------------------------------------|----------------------------------------------|
| <b>Routing algorithm</b> | Distance vector, basic      | Distance vector, advanced                             | Link-state                                   |
| <b>Common uses</b>       | Small, non-complex networks | Network backbone, ties multinational offices together | Common in large, complex enterprise networks |

| Protocol              | RIP                                                                                              | BGP                                                   | OSPF / IS-IS                                  |
|-----------------------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------|-----------------------------------------------|
| <b>Strengths</b>      | Fast and simple to implement                                                                     | Graceful restart                                      | Fast convergence                              |
|                       | Near universal support                                                                           | BFD support                                           | Robust                                        |
|                       | Good when no redundant paths                                                                     | Only needed on border routers                         | Little management overhead                    |
|                       |                                                                                                  | Summarize routes                                      | No hop count limitation                       |
|                       |                                                                                                  |                                                       | Scalable                                      |
| <b>Weakness</b>       | Frequent updates can flood network                                                               | Required full mesh in large networks can cause floods | Complex                                       |
|                       | Slow convergence                                                                                 | Route flap                                            | No support for unequal cost multipath routing |
|                       | Maximum 15 hops may limit network configuration                                                  | Load-balance multi-homed networks                     | Route summary can require network changes     |
|                       |                                                                                                  | Not available on low-end routers                      |                                               |
| <b>Authentication</b> | Optional authentication using text string or MD5 password.<br><br>(RIP v1 has no authentication) |                                                       |                                               |
| <b>IPv6 support</b>   | Only in RIPng                                                                                    | Only in BGP4+                                         | Only in OSPF6 / Integrated IS-IS              |

## Routing protocols

- **Routing Information Protocol (RIP)** uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.
- **Border Gateway Protocol (BGP)** has been the core Internet backbone routing protocol since the mid-1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.
- **Open Shortest Path First (OSPF)** is commonly used in large enterprise networks. It is the protocol of choice, mainly due to its fast convergence. However, it can be complicated to setup properly.
- **Intermediate System to Intermediate System (IS-IS) Protocol** allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware.
- **Multicast** addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

## Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the “intelligent” part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information about the routing algorithm used, see [Comparison of dynamic routing protocols on page 2506](#).

## Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of these types of threats. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers because all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When you configure authentication on your network, ensure that you configure it the same way on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of 123 on an OSPF interface called `ospf_test`, enter the following CLI commands:

```
config router ospf
 config ospf-interface
 edit ospf_test
 set authentication md5
 set md5-key 123
 end
 end
end
```

## Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems, such as network loops, which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways, they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem, short of a total network failure.

## IPv6 support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols supported IPv6 originally, but they all have additions, expansions, or new versions that now support IPv6. For more information, see [RIP on page 2519](#), [BGP on page 2598](#), [OSPF on page 2557](#), or [IS-IS on page 2637](#).

## When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- [Budget](#)
- [Current network size and topology](#)
- [Expected network growth](#)
- [Available resources for ongoing maintenance](#)

### Budget

When making any business decision, you must always consider your budget. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, will need to support the routing protocols that you choose. Network management software and routing protocol drivers may also be necessary to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, you must budget either a training course or some hands-on learning time so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

### Current network size and topology

As stated earlier, static routing works well on small networks. As those networks get larger, routing takes longer, routing tables get very large, and general performance is not what it could be.

Topology is a concern as well. If all your computers are in one building, it is much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and do not worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be slower, more complex, and there will not be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size and topology.

### Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before the new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when the new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, the labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, the new routers can help share the load in most dynamic routing configurations. For example, if you have 4 OSPF routers and 20,000 external routes, those few routers will be overwhelmed. But a network with 15 OSPF routers will be better able to handle that number of routes. However, be aware that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

### Available resources for ongoing maintenance

As explained in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator (if needed), extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time
- Routing hardware updates will require time
- Office reorganizations or significant personnel movement will require time from a networking point of view
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem

If resources to accomplish these tasks are not budgeted, the tasks will either not happen at the required level to continue operation or not happen at all. This will result in both the network administration staff and the network users being very frustrated.

A lack of a maintenance budget will also result in an increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

## Choosing a routing protocol

One of the hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols, including their strongest and weakest points. The steps to choosing your routing protocol are:

1. [Answer questions about your network](#)
2. [Evaluate your chosen protocol](#)
3. [Implement your dynamic routing protocol](#)

### Answer questions about your network

Before you can decide what is best for your situation, you need to examine the details of your situation, such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

#### How many computers or devices are on your network?

The number of computers or devices that you have on your network, and whether the devices are all in one location or distributed, matters. All routing protocols can be run on networks of any size, but it can be inefficient to run some routing protocols on very small networks. Also, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

#### What applications typically run over the network?

Finding out what applications your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

#### What level of service do the users expect from the network?

Different users have different expectations of the network. It's not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

#### Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you do not have to change technologies again down the road.

#### What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

#### Is security a major concern?

Some routing protocols have levels of authentication and other security features built in, and others do not. If security is important to you, be aware of this.

## What is your budget?

You need to know what both your initial and maintenance budget is. More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also, more secure configurations require still more resources. This includes both set up costs and ongoing maintenance costs. If you ignore these costs, you risk having to drop the adoption of the new routing protocol mid-change.

## Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test installation of that protocol.

The test installation is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test installation is to prove that it will work on a larger scale on your network. You must ensure that the test installation mirrors your larger network well enough for you to discover any problems. If the test installation is too simple, these problems may not appear.

If your chosen protocol does not meet your goals, choose a different protocol and repeat the evaluation process until a protocol meets your needs or you change your criteria.

## Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide, as needed, during your implementation to help ensure a smooth transition. Examples for each protocol are included to show proper configurations for different types of networks.

## Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It is more complicated by the fact that each routing protocol has different names for similar features, as well as many features that you can configure for each protocol.

To better understand dynamic routing, the following sections provide explanations on common dynamic routing terms

For more details about a term, as it applies to a dynamic routing protocol, see [BGP on page 2598](#), [RIP on page 2519](#), or [OSPF on page 2557](#).

### Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one route. This reduces the amount of space those routes require in the routing tables of the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating, you need to decide if it is better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information about aggregated routes in BGP, see [BGP on page 2598](#).

## To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

### 1. Convert the addresses to binary:

```
192.168.1.100 = 11000000 10101000 00000001 01100100
192.168.1.101 = 11000000 10101000 00000001 01100101
192.168.1.102 = 11000000 10101000 00000001 01100110
192.168.1.103 = 11000000 10101000 00000001 01100111
```

### 2. Determine the maximum number of matching bits common to the addresses.

There are 30-bits in common, with only the last 2-bits being different.

### 3. Record the common part of the address:

```
11000000 10101000 00000001 0110010X = 192.168.1.100
```

### 4. For the netmask, assume all the bits in the netmask are 1, except those that are different (which are 0):

```
11111111 11111111 11111111 11111100 = 255.255.255.252
```

### 5. Combine the common address bits and the netmask:

```
192.168.1.100/255.255.255.252
```

Alternately, the IP mask may be written as a single number:

```
192.168.1.100/2
```

### 6. As required, set variables and attributes to declare that the routes have been aggregated, and which router did the aggregating.

## Autonomous system

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example, an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP, it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of ASs, which are defined by how they are connected to other ASs. A multihomed AS is connected to at least two other ASs and has the benefit of redundancy: if one of those ASs goes down, your AS can still reach the Internet through its other connection. A stub AS has only one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS), you need to have an officially registered ASN from the Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

NAs of January 2010, AS numbers are 4 bytes long, instead of the former 2 bytes. [RFC 4893](#) introduced 32-bit ASNs, which FortiGate units support for BGP and OSPF.

## Do you need your own AS?

The main factors in deciding if you need your own AS, or if you should be part of someone else's are:

- Exchanging external routing information
- Many prefixes should exist in one AS as long as they use the same routing policy
- When you use a different routing protocol than your border gateway peers. For example, your ISP uses BGP and you use OSPF.
- Connected to many other ASs (multi-homed)

You should not create an AS for each prefix on your network. You also should not be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

### What AS number should you use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers range from 1 to 64,511. The ASNs 0, 54272 to 64511, and 65535 are reserved by the IANA and should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIR), who then assign ASNs to companies within the geographic area of the RIR. These companies are usually ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The following table shows the names and regions of the RIRs:

|                 |                                                                       |
|-----------------|-----------------------------------------------------------------------|
| <b>AFRINIC</b>  | Serves the African continent                                          |
| <b>APNIC</b>    | Asia-Pacific, including China, India, and Japan                       |
| <b>ARIN</b>     | American registry, including Canada and United States                 |
| <b>LACNIC</b>   | Latin America, including Mexico, Caribbean, Central and South America |
| <b>RIPE NCC</b> | Europe, the Middle East, the former USSR, and parts of Central Asia   |

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet, such as test networks, classroom labs, and other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts could happen. It would be like your local 192.168.0.0 network being made public and the resulting problems would be widespread.

In 1996, when [RFC 1930](#) was written, only 5,100 ASs had been allocated and a little under 600 ASs were actively routed in the global Internet. Since that time, many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. [RFC 4893](#) defines 32-bit ASNs, and FortiGate units support these larger ASNs.

### Area border router

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and routers external to their AS, which are often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. ABRs often run multiple routing protocols in order to redistribute traffic between different ASs that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains an LSA database for each area that it is connected to. The concept of the edge router is present, but it is the edge of the backbone instead of the edge of the OSPF supported ASs.

## Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality that other routers lack. Neighbor routers are sometimes called peers.

Generally, neighbor routers must be configured and discovered by the rest of the network before they can be integrated into the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

## Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates and sent route updates. This can include the redistribution of routes learned from other types of routing. For example, if you do not want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. During your configuration, you can use these route-maps to speed up configuration. The meaningful names also ensure that fewer mistakes are made during configuration.

The default rule in the route map, which the FortiGate unit applies last, denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
 edit <route_map_name>
 set comments
 config rule
 edit <route_map_rule_id>
 set action
 set match-*
 set set-*
 ...
 end
 end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see [BGP on page 2598](#).

### Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or match the prefix and a more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 cannot be exactly matched with an access-list. A prefix-list must be used for this purpose.

---

The FortiGate unit attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found, the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
 edit <access_list_name>
 set comments
 config rule
 edit <access_list_id>
 set action
 set exact-match
 set prefix
 set prefix6
 set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see [BGP on page 2598](#).

### Bi-directional forwarding detection

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared to be down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF, or BFP routers establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
 config neighbor
 set bfd
end
config router ospf
 set bfd
```

```
end
```

Per-VDOM configuration:

```
config system settings
 set bfd
 set bfd-desired-min-tx
 set bfd-required-min-rx
 set bfd-detect-mult
 set bfd-dont-enforce-src-port
end
```

Per-interface (override) configuration:

```
config system interface
 edit <interface_name>
 set bfd enable
 set bfd-desired-min-tx
 set bfd-detect-mult
 set bfd-required-min-rx
 end
```

For more information about BFD in BGP, see [BGP on page 2598](#).

## Controlling how routing changes affect active sessions

Dynamic routing changes can occur while the FortiGate unit is processing traffic. Routing changes that affect the routes being used for current sessions, may affect how the FortiGate continues to process the session. In FortiOS 5.6.1 and later, you can control how active sessions are affected when dynamic routing changes occur that affects the routes the active sessions are using.

You can configure whether the FortiGate maintains the original routing for the sessions that are using the affected routes, or applies the routing table changes to the active sessions, which may cause destinations to change.

### Configure how dynamic routing changes affect active sessions

To configure how dynamic routing changes affect active sessions, use the following CLI commands:

```
config system interface
 edit <port#>
 set preserve-session-route {enable | disable}
 end
```

| CLI option        | Description                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <port#1>          | The name of the interface where you want to configure how dynamic routing changes affect active sessions running through it.                                                                   |
| enable            | All sessions passing through the interface when the routing changes occur, are allowed to finish and are not affected by the routing changes.                                                  |
| disable (default) | When a routing change occurs, the new routing table is applied to the active sessions passing through the interface. The routing changes may cause the destinations of the sessions to change. |

## IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — [RFC 2080](#) - Routing Information Protocol next generation (RIPng). See RIP and IPv6.
- **BGP4+** — [RFC 2545](#), and [RFC 2858](#) Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See BGP and IPv6.
- **OSPFv3** — [RFC 2740](#) Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See OSPFv3 and IPv6.
- **Integrated IS-IS** — [RFC 5308](#) for IPv6 support. See Integrated IS-IS.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Admin > Settings**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

## RIP

This section describes the Routing Information Protocol (RIP).

### RIP background and concepts

#### Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The Bellman–Ford algorithm, which is the routing algorithm used by RIP, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP has many benefits. It is well suited to smaller networks, has near universal support on routing hardware, is quick to configure, works well if there are no redundant paths, and is in widespread use. However, because RIP updates are sent out node-by-node, it can be slow to find a path around network outages. RIP also lacks good authentication, cannot choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see [RFC 1058](#)), RIP version 2 (see [RFC 2453](#)), and the IPv6 version RIPvng (see [RFC 2080](#)).

#### RIPv1

In 1988, RIP version 1 (RIPv1) was released. It is defined in [RFC 1058](#). It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing. It does not support CIDR addressing and subnets must all be the same size. Also, route summarization is not possible. RIPv1 has no router authentication method, so it is vulnerable to attacks through packet sniffing and spoofing.

#### RIPv2

In 1993, RIP version 2 (RIPv2) was developed to deal with the limitations of RIPv1. It was not standardized until 1998. This new version supports classless routing and subnets of various sizes. Router authentication was added, which supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all. In RIPv2, the hop count limit remained at 15, in order to be backwards compatible with RIPv1. It also uses multicasting to send the entire routing table to router neighbors, which reduces the traffic for devices that are not participating in RIP routing. Routing tags were also added, which allow internal routes or redistributed routes to be identified as such.

#### RIPvng

RIPvng, defined in [RFC 2080](#), is an extension of RIPv2 and is designed to support IPv6. However, RIPvng varies from RIPv2 in that it is not fully backwards compatible with RIPv1. RIPvng does not support RIPv1 update authentication and relies on IPsec instead. It does not allow the attaching of tags to routes, as in RIPv2. RIPvng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

## RIP terminology and parts

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

### RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP and includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also, if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ipv6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in transparent mode.

For example, if you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01::, where it will need access to an IPv4 network again, use the following commands:

```
config system ipv6-tunnel
 edit test_tunnel
 set destination 2002:A0A:A01::
 set interface port1
 set source 2002:C0A8:3201::
 end
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

### Default information originate option

The default information originate option is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
 set default-information-originate
```

end

## Update, timeout, and garbage timers

RIP uses various timers to regulate its performance including an update timer, a timeout timer, and a garbage timer. The FortiGate unit's default timer settings (30, 180, and 120 seconds) are effective in most configurations. If you change these settings, ensure that the new settings are compatible with local routers and access servers.

The timeout period should be at least three times longer than the update period. If the update timer is smaller than the timeout or garbage timers, you will experience an error.

You can set the three RIP timers in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
 set timeout-timer
 set update-timer
 set garbage-timer
end
```

### Update timer

The update timer determines the interval between routing updates. This value is usually set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers attempting to update their neighbors simultaneously. The update timer should be at least three times smaller than the timeout timer or you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

### Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period or you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods. It may be a considerable amount of time before the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

### Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove older ones faster. This will result in a smaller routing table, which is useful if you have a very large network, or if your network changes frequently.

## Authentication and key chain

RIP version 2 (RIPv2) uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 (RIPv1) has no authentication. For authentication to work, both the sending and

receiving routers must be set to use authentication and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys, including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

The key-chain command is a CLI router command. You use this command to manage RIPv2 authentication keys. You can add, edit, or delete keys identified by the specified key number.

This example shows how to configure a key chain with two keys that are valid sequentially in time. This example creates a key chain called "rip\_key" that has a password of "fortinet". The accepted and send lifetimes are both set to the same values: a start time of 9:00 am on February 23, 2010 and an end time of 9:00 am on March 17, 2010. A second key is configured with a password of "my\_fortigate" that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This "rip\_key" key chain is then used on the port1 interface in RIP.

```
config router key-chain
 edit "rip_key"
 config key
 edit 1
 set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
 set key-string "fortinet"
 set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
 next
 edit 2
 set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
 set key-string "my_fortigate"
 set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
 next
 end
 end
end
config router rip
 config interface
 edit port1
 set auth-keychain "rip_key"
 end
 end
end
```

The CLI commands associated with authentication keys include:

```
config router key-chain

config router rip
 config interface
 edit <interface>
 set auth-keychain
 set auth-mode
 set auth-string
 end
 end
end
```

## Access lists

Access lists are filters used by the FortiGate unit's RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them. Essentially, an access list makes it easy to group addresses that will be treated the same way into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include and specify the action to take for it. For example, if you want all traffic from one department to be routed a particular way, even in different buildings, you can add all of the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found, the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also, it is easier to troubleshoot because if all addresses on one list have problems, many possible causes can be eliminated right away.

If you are using the RIPng or OSPF+ IPv6 protocols, you will need to use access-list6, which is the IPv6 version of the access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of 10.10.10.10 and 11.11.11.11, enter the command:

```
config router access-list
 edit test_list
 config rule
 edit 1
 set prefix 10.10.10.10 255.255.255.255
 set action allow
 set exact-match enable
 next
 edit 2
 set prefix 11.11.11.11 255.255.255.255
 set action allow
 set exact-match enable
 end
 end
 end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the access-list6 command, as follows:

```
config router access-list6
 edit test_list_ip6
 config rule
 edit 1
 set prefix6 2002:A0A:A0A:0:0:0:0:0/48
 set action deny
 next
 edit 2
 set prefix6 2002:B0B:B0B:0:0:0:0:0/48
 set action deny
 end
 end
 end
```

To use an access list, you must call it from a routing protocol, such as RIP. The following example uses the access list from the previous example, called `test_list`, to match routes coming in on the `port1` interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase. Enter the following command:

```
config router rip
 config offset-list
 edit 5
 set access-list test_list
 set direction in
 set interface port1
 set offset 3
 set status enable
 end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 cannot be exactly matched with an access list. A prefix list must be used for this purpose

## How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm is not complex and there are some options that allow fine tuning. It is relatively simple to configure RIP on FortiGate units.

From [RFC 1058](#):

*Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.*

This section includes:

- [RIP versus static routing](#)
- [RIP hop count](#)
- [The Bellman–Ford routing algorithm](#)
- [Passive versus active RIP interfaces](#)
- [RIP packet structure](#)

## RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence; static routing has zero convergence. Both RIP and static routing have the limited hop count, so it is not a strength or a weakness. Count to infinity can be a problem, but can typically be fixed as it happens, or is the result of a network outage that would cause even worse problems on a static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate unit can send it only to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so your FortiGate unit can send the packet further towards its destination before it has to be routed again toward its destination. RIP uses a smaller amount of table lookups,

and therefore fewer network resources, than static routing. Also, since RIP is updated on neighboring routes, it is aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

## RIP hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in [RIP packet structure on page 2529](#), the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly, you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it is very easy to reach the upper limit. This higher weighting will effectively limit the size of your network, depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the `offset` command to artificially increase the hop count of a route. Doing this will make this route less preferred and, in turn, it will get less traffic. Offsetting routes is useful when you have network connections that have different bandwidths, levels of reliability, or costs. In each of these situations you still want the redundancy of multiple route access, but you do not want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see [Access lists on page 2523](#).

## The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let us look at a network with 4 routers: routers 1 through 4. The distance from Router1 to Router2 is 2 hops, Router1 to Router3 is 3 hops, and Router2 to Router3 is 4 hops. Router4 is only connected to Router2 and Router3, each distance being 2 hops.

1. Router1 finds all of the distances to the other three routers: Router 2 is 2, Router 3 is 3. Router1 does not have a route to Router4.
2. Router2, Router3, and Router4 perform the same calculations from their point of views.
3. Once Router1 gets an update from Router 2 or Router3, it will get their route to Router4. At that point, it now has a route to Router4 and installs that in its local table.

4. If Router1 gets an update from Router3 first, it has a hop count of 5 to reach Router4, but when Router2 sends its update, Router1 will go with Router2's shorter 4 hops to reach Router4. Future updates do not change this unless they are shorter than 4 hops or the routing table route goes down.

### RIP algorithm example in four steps

#### Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops

#### Step 2

All routers do the same as Router1 and send out updates containing their routing table.

Note that Router1 and Router4 do not update each other, but rely on Router2 and Router3 to pass along accurate updates.

### Step 3

Each router looks at the updates it has received and adds any new or shorter routes to its table.

Router1's updated table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops
- Distance to Router4 = 4 or 5 hops

### Step 4

Router1 installs the shortest route to Router4 and the other routes to it are removed from the routing table.

Router1's complete table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops

- Distance to Router4 = 4 hops

The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, and therefore less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see [RIP packet structure on page 2529](#).

The main disadvantage of the Bellman-Ford algorithm in RIP is that it does not take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size by reducing the hop count limit. Also, other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest routes but also the fastest or more reliable routes.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down and that wastes time and network resources.

### Passive versus active RIP interfaces

Normally, the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

A standard interface that supports RIP is active, by default. It sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates. It only listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that will send out essentially the same updates all the time.

The following example shows how to create a passive RIPv2 interface on port1 using MD5 authentication and a key chain called `passiveRIPv2`, which has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

### To create a passive RIP interface - web-based manager

1. Go to **Router > Dynamic > RIP**.
2. Next to **Interfaces**, select **Create**.
3. Select port1 as the **Interface**.
4. Select 2 as both the **Send Version** and **Receive Version**.
5. Select MD5 for **Authentication**.
6. Select the `passiveRIPv2` **Key-chain**.
7. Select **Passive Interface**.
8. Select **OK** to accept this configuration and return to the main RIP display page.

### To create a passive RIP v2 interface on port1 using MD5 authentication - CLI

```
config router rip
 config interface
 edit port1
 set send-version2-broadcast disable
 set auth-keychain "passiveRIPv2"
 set auth-mode md5
 set receive-version 2
 set send-version 2
 end
 end
end
```

### RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how it is exchanged will help you to better understand the RIP protocol and better configure your network for it.

This section provides information about the contents of RIPv1 and RIPv2 packets.

#### RIP version 1

RIP version 1 (RIPv1), or RIP IP, packets are 24 bytes in length with some empty areas left for future expansion.

#### RIP IP packets

|                   |                   |                   |               |                   |
|-------------------|-------------------|-------------------|---------------|-------------------|
| 1-byte command    | 1-byte version    | 2-byte zero field | 2-byte AFI    | 2-byte zero field |
| 4-byte IP address | 4-byte zero field | 4-byte zero field | 4-byte metric |                   |

A RIPv1 packet contains the following fields:

- **Command:** Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.
- **Version:** Specifies the RIP version used. This field can signal different, potentially incompatible versions.
- **Zero field:** This field defaults to zero and is not used by [RFC 1058](#) RIP.
- **Address-family identifier (AFI):** Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.

- **IP Address:** Specifies the IP address for the entry.
- **Metric:** This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable, the metric is 16.

## RIP version 2

RIP version 2 (RIPv2) has more features than RIPv1, which is reflected in its packets that carry more information. All but one of the empty zero fields in RIPv1 packets are used in RIPv2.

### RIPv2 packets

|                   |                |                 |               |                  |
|-------------------|----------------|-----------------|---------------|------------------|
| 1-byte command    | 1-byte version | 2-byte unused   | 2-byte AFI    | 2-byte route tag |
| 4-byte IP address | 4-byte subnet  | 4-byte next hop | 4-byte metric |                  |

A RIPv2 packet contains the fields described above for RIPv1, as well as the following:

- **Unused:** Has a value set to zero and is intended for future use
- **Route tag:** Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.
- **Subnet mask:** Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.
- **Next hop:** Indicates the IP address of the next hop to which packets for the entry should be forwarded.

## Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the FortiOS Handbook Troubleshooting chapter.

### Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself, creating a loop. When there are loops, the network has problems getting information to its destination. Loops also prevent the network from returning to the source to report the inaccessible destination.

A routing loop occurs when a normally functioning network has an outage and one or more routers are offline. When packets encounter this, they attempt an alternate route maneuver around the outage. During this phase, it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is also blocked by the outage, a hop back, and possibly the original hop forward, may be selected. If this continues, it can consume not only network bandwidth but also many resources on the affected routers. The worst part is this situation will continue until the network administrator changes the router settings or the downed routers come back online.

### Effect of routing loops on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes, that router sends an update out to all of the RIP routers connected to it. In a network loop, it is possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

## How to spot a routing loop

Anytime network traffic slows down, you will ask yourself if it is a network loop. Slowdowns are often normal, are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown that does not return to normal quickly, you need to do serious troubleshooting quickly.

If you are not running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic and are covered in [Advanced static routing on page 2473](#).

## Check your logs

If your routers log events to a central location, it can be easy to check your network logs for any outages.

On your FortiGate unit, go to **Log & Report**. You should look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

## Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and its location as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

## To use SNMP to detect potential routing loops

1. Go to **System > Config > SNMP**.
2. Enable **SMTP Agent** and select **Apply**.  
Optionally, enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
3. Under **SNMP v1/v2** or **SNMP v3** as appropriate, select **Create New**.  
**SNMP v3**

|                          |                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>User Name</b>         | Enter the SNMP user ID.                                                                                                               |
| <b>Security Level</b>    | Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords. |
| <b>Notification Host</b> | Enter the IP addresses of up to 16 hosts to notify.                                                                                   |

**Enable Query**

Select. The **Port** should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

**SNMP v1/v2****Hosts**

Enter the IP addresses of up to 8 hosts to notify.

**Queries**

Enable **v1** and/or **v2** as needed. The **Port** should be 161. Ensure that your security policies allow port 161 to pass.

**Traps**

Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include **CPU usage is high**, **Memory is low**, and possibly **Log disk space is low**. If there are problems the log will fill up quickly and the FortiGate unit's resources will be overused.
5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

**Use Link Health Monitor and email alerts**

Another tool available to you on FortiGate units is the Link Health Monitor, which is useful for dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

**To detect possible routing loops with Link Health Monitor and email alerts**

Use the following command to configure dead gateway detection:

```
config system link-monitor
edit "test"
set srcintf "internal4"
set server "8.8.8.8"
set interval 5
set failtime 1
end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

**To configure notification of failed gateways**

1. Go to **Log & Report > Report > Local** and enable **Email Generated Reports**.
2. Enter your email details.
3. Select **Apply**.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

### Look at the packet flow

If you want to see what is happening on your network, look at the packets traveling on the network. This is the same idea as police pulling over a car and asking the driver where they have been and what the conditions were like.

The method used in the troubleshooting sections [Debugging IPv6 on RIPng on page 2534](#) and on debugging the packet flow also apply here. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally, if you debug the flow of the packets and record the routes that are unreachable, you can create an accurate picture of the network outage.

### Action to take on discovering a routing loop

Once you have mapped the problem on your network and determined that it is a routing loop, there are a number of steps you can take to correct it:

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often, this first step will restore your network to its normal operation, once the routing tables are updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

### Holddowns and triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there is a change to the routing table. If your network has many RIP routers, these updates can start to slow your network down. Also, if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out and help prevent a potential flood.

### Holddown timers

The holddown timer activates when a route is marked down. Until the timer expires, the router does not accept any new information about that route. This is very useful if you have a flapping route because it will prevent your router from sending out updates and being part of the problem in flooding the network. The potential downside is if the route comes back up before the timer expires, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

## Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table will only be updated when a specific request is sent to update, instead of every time the routing table changes. Updates are also triggered when a unit is 'powered on', which can include the addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

## Split horizon and poison reverse updates

Split horizon is best explained with an example. If there are three routers linked serially, called routerA, routerB, and routerC. RouterA is only linked to routerB, RouterC is only linked to routerB, and routerB is linked to both routerA and routerC. To get to routerC, routerA must go through routerB. If the link to routerC goes down, it is possible that routerB will try to use routerA's route to get to routerC. This route is A-B-C, so it will loop endlessly between routerA and routerB.

This situation is called a split horizon because from routerB's point of view the horizon stretches out in each direction but in reality it is only on one side. Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This poisoned route is marked as unreachable for routers that cannot use it. In RIP, this means that the route is marked with a distance of 16.

## Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit, including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging, in general
- set the debug level to information, which is a verbose reporting level
- turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable, since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a reply received in response.

For more information, see [Troubleshooting RIP on page 2530](#).

## Simple RIP example

This is an example of a typical medium-sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route for redundancy. There are two central routers that are both connected to the Internet and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running, those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

## Network layout and assumptions

### Basic network layout

Your company has 3 departments each with their own network: Sales, R&D, and Accounting. Each network has routers that are not running RIP and FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

Where possible in this example, the default values will be used (or the most general settings). This is intended to provide an easier configuration that will require less troubleshooting.

In this example, the routers, networks, interfaces used, and IP addresses are as follows. Note that the interfaces that connect Router2 and Router3 also connect to the R&D network.

### RIP example network topology

| Network | Router  | Interface & alias | IP address    |
|---------|---------|-------------------|---------------|
| Sales   | Router1 | port1 (internal)  | 10.11.101.101 |
|         |         | port2 (router2)   | 10.11.201.101 |
|         |         | port3 (router3)   | 10.11.202.101 |

| Network    | Router  | Interface & alias | IP address     |
|------------|---------|-------------------|----------------|
| R&D        | Router2 | port1 (internal)  | 10.12.101.102  |
|            |         | port2 (router1)   | 10.11.201.102  |
|            |         | port3 (router4)   | 10.14.201.102  |
|            |         | port4 (ISP)       | 172.20.120.102 |
|            | Router3 | port1 (internal)  | 10.12.101.103  |
|            |         | port2 (router1)   | 10.11.201.103  |
|            |         | port3 (router4)   | 10.14.202.103  |
|            |         | port4 (ISP)       | 172.20.120.103 |
| Accounting | Router4 | port1 (internal)  | 10.14.101.104  |
|            |         | port2 (router2)   | 10.14.201.104  |
|            |         | port3 (router3)   | 10.14.202.104  |

Network topology for the simple RIP example

## Assumptions

The following assumptions have been made concerning this example:

- All FortiGate units have 5.0 firmware and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labeled port1 through port4, as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in the diagram above.

## General configuration steps

This example is very straightforward. The only steps involved are:

- [Configuring FortiGate system information](#)
- [Configuring FortiGate unit RIP router information](#)
- [Configuring other networking devices](#)
- [Testing network configuration](#)

## Configuring FortiGate system information

You must configure the hostname and interfaces for each FortiGate.

For IP numbering, Router2 and Router3 use the numbering for the other routers, where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

## Configure the hostname, interfaces, and default route

### To configure Router1 system information - web-based manager

1. Go to **System > Settings**.
2. In the **Host name** field, enter `Router1`.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

|                                |                            |
|--------------------------------|----------------------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0            |
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port2 (router2)            |
| <b>Administrative Distance</b> | 40                         |

5. Enter a second default route and enter the following information:

|                            |                 |
|----------------------------|-----------------|
| <b>Destination IP/Mask</b> | 0.0.0.0/0.0.0.0 |
|----------------------------|-----------------|

|                                |                            |
|--------------------------------|----------------------------|
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port3 (router3)            |
| <b>Administrative Distance</b> | 40                         |

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

|                              |                             |
|------------------------------|-----------------------------|
| <b>Alias</b>                 | internal                    |
| <b>IP/Network Mask</b>       | 10.11.101.101/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING              |
| <b>Comments</b>              | Internal sales network      |
| <b>Interface State</b>       | Enabled                     |

9. Edit port2 (router2) interface.
10. Set the following information, and select **OK**.

|                              |                                                |
|------------------------------|------------------------------------------------|
| <b>Alias</b>                 | router2                                        |
| <b>IP/Network Mask</b>       | 10.11.201.101/255.255.255.0                    |
| <b>Administrative Access</b> | HTTPS SSH PING                                 |
| <b>Comments</b>              | Link to R&D network & Internet through Router2 |
| <b>Interface State</b>       | Enabled                                        |

11. Edit port3 (router3) interface.
12. Set the following information, and select **OK**.

|                              |                                                  |
|------------------------------|--------------------------------------------------|
| <b>Alias</b>                 | router3                                          |
| <b>IP/Network Mask</b>       | 10.11.202.101/255.255.255.0                      |
| <b>Administrative Access</b> | HTTPS SSH PING                                   |
| <b>Comments</b>              | Link to R&D network and Internet through Router3 |
| <b>Interface State</b>       | Enabled                                          |

#### To configure Router1 system information - CLI

```
config system global
set hostname Router1
```

```

end

config router static
 edit 1
 set device "port2"
 set distance 45
 set gateway 10.11.201.102
 next
 edit 2
 set device "port3"
 set distance 45
 set gateway 10.11.202.103
 end
end

config system interface
 edit port1
 set alias internal
 set ip 10.11.101.101/255.255.255.0
 set allowaccess https ssh ping
 set description "Internal sales network"
 next
 edit port2
 set alias ISP
 set allowaccess https ssh ping
 set ip 10.11.201.101/255.255.255.0
 set description "Link to R&D network & Internet through Router2"
 next
 edit port3
 set alias router3
 set ip 10.11.202.101/255.255.255.0
 set allowaccess https ssh ping
 set description "Link to R&D network & Internet through Router2"
 end
end

```

### To configure Router2 system information - web-based manager

1. Go to **System > Settings**.
2. In the **Host name** field, enter `Router2`.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

|                                |                            |
|--------------------------------|----------------------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0            |
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port4 (ISP)                |
| <b>Administrative Distance</b> | 5                          |

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information and select **OK**.

|                              |                                  |
|------------------------------|----------------------------------|
| <b>Alias</b>                 | internal                         |
| <b>IP/Network Mask</b>       | 10.12.101.102/255.255.255.0      |
| <b>Administrative Access</b> | HTTPS SSH PING                   |
| <b>Comments</b>              | R&D internal network and Router3 |
| <b>Interface State</b>       | Enabled                          |

8. Edit port2 (router1) interface.

9. Set the following information and select **OK**.

|                              |                                       |
|------------------------------|---------------------------------------|
| <b>Alias</b>                 | router1                               |
| <b>IP/Network Mask</b>       | 10.12.201.102/255.255.255.0           |
| <b>Administrative Access</b> | HTTPS SSH PING                        |
| <b>Comments</b>              | Link to Router1 and the Sales network |
| <b>Interface State</b>       | Enabled                               |

10. Edit port3 (router4) interface.

11. Set the following information and select **OK**.

|                              |                                            |
|------------------------------|--------------------------------------------|
| <b>Alias</b>                 | router4                                    |
| <b>IP/Network Mask</b>       | 10.12.301.102/255.255.255.0                |
| <b>Administrative Access</b> | HTTPS SSH PING                             |
| <b>Comments</b>              | Link to Router4 and the accounting network |
| <b>Interface State</b>       | Enabled                                    |

12. Edit port4 (ISP) interface.

13. Set the following information and select **OK**.

|                                    |                              |
|------------------------------------|------------------------------|
| <b>Alias</b>                       | ISP                          |
| <b>IP/Network Mask</b>             | 172.20.120.102/255.255.255.0 |
| <b>Administrative Access</b>       | HTTPS SSH PING               |
| <b>Detect and Identify Devices</b> | enable                       |
| <b>Comments</b>                    | Internet through ISP         |
| <b>Interface State</b>             | Enabled                      |

### To configure Router2 system information - CLI

```

config system global
 set hostname Router2
end
config router static
 edit 1
 set device "port4"
 set distance 5
 set gateway 172.20.130.5
 end
end
config system interface
 edit port1
 set alias internal
 set ip 10.11.101.102/255.255.255.0
 set allowaccess https ssh ping
 set description "Internal RnD network and Router3"
 next
 edit port2
 set alias router1
 set allowaccess https ssh ping
 set ip 10.11.201.102/255.255.255.0
 set description "Link to Router1"
 next
 edit port3
 set alias router3
 set ip 10.14.202.102/255.255.255.0
 set allowaccess https ssh ping
 set description "Link to Router4"
 next
 edit port4
 set alias ISP
 set ip 172.20.120.102/255.255.255.0
 set allowaccess https ssh ping
 set description "ISP and Internet"
 end
end

```

### To configure Router3 system information - web-based manager

1. Go to **System > Settings**.
2. In the **Host name** field, enter `Router3`.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

|                                |                            |
|--------------------------------|----------------------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0            |
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port4 (ISP)                |
| <b>Administrative Distance</b> | 5                          |

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information and select **OK**.

|                              |                                  |
|------------------------------|----------------------------------|
| <b>Alias</b>                 | internal                         |
| <b>IP/Network Mask</b>       | 10.12.101.103/255.255.255.0      |
| <b>Administrative Access</b> | HTTPS SSH PING                   |
| <b>Comments</b>              | R&D internal network and Router2 |
| <b>Interface State</b>       | Enabled                          |

8. Edit port2 (router1) interface.
9. Set the following information and select **OK**.

|                              |                                   |
|------------------------------|-----------------------------------|
| <b>Alias</b>                 | router1                           |
| <b>IP/Network Mask</b>       | 10.13.201.103/255.255.255.0       |
| <b>Administrative Access</b> | HTTPS SSH PING                    |
| <b>Comments</b>              | Link to Router1 and Sales network |
| <b>Interface State</b>       | Enabled                           |

10. Edit port3 (router4) interface.
11. Set the following information and select **OK**.

|                              |                                        |
|------------------------------|----------------------------------------|
| <b>Alias</b>                 | router4                                |
| <b>IP/Network Mask</b>       | 10.13.301.103/255.255.255.0            |
| <b>Administrative Access</b> | HTTPS SSH PING                         |
| <b>Comments</b>              | Link to Router4 and accounting network |
| <b>Interface State</b>       | Enabled                                |

12. Edit port4 (ISP) interface.
13. Set the following information and select **OK**.

|                              |                              |
|------------------------------|------------------------------|
| <b>Alias</b>                 | ISP                          |
| <b>IP/Network Mask</b>       | 172.20.120.103/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING               |

|                                    |                  |
|------------------------------------|------------------|
| <b>Detect and Identify Devices</b> | enable           |
| <b>Comments</b>                    | Internet and ISP |
| <b>Interface State</b>             | Enabled          |

### To configure Router3 system information - CLI

```

config system global
 set hostname Router3
end
config router static
 edit 1
 set device "port4"
 set distance 5
 set gateway 172.20.130.5
 end
end
config system interface
 edit port1
 set alias internal
 set ip 10.12.101.103/255.255.255.0
 set allowaccess https ssh ping
 set description "Internal RnD network and Router2"
 next
 edit port2
 set alias ISP
 set allowaccess https ssh ping
 set ip 10.11.201.103/255.255.255.0
 set description "Link to Router1"
 next
 edit port3
 set alias router3
 set ip 10.14.202.103/255.255.255.0
 set allowaccess https ssh ping
 set description "Link to Router4"
 next
 edit port4
 set alias ISP
 set ip 172.20.120.103/255.255.255.0
 set allowaccess https ssh ping
 set description "ISP and Internet"
 end
end
end

```

### To configure Router4 system information - web-based manager

1. Go to **System > Settings**.
2. In the **Host name** field, enter Router4.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

|                                |                            |
|--------------------------------|----------------------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0            |
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port2 (router2)            |
| <b>Administrative Distance</b> | 40                         |

5. Enter a second default route and enter the following information:

|                                |                            |
|--------------------------------|----------------------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0            |
| <b>Gateway</b>                 | 172.20.120.5/255.255.255.0 |
| <b>Interface</b>               | port3 (router3)            |
| <b>Administrative Distance</b> | 40                         |

6. Go to **Network > Interfaces**.  
7. Edit port 1 (internal) interface.  
8. Set the following information and select **OK**.

|                              |                             |
|------------------------------|-----------------------------|
| <b>Alias</b>                 | internal                    |
| <b>IP/Network Mask</b>       | 10.14.101.104/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING              |
| <b>Comments</b>              | Internal accounting network |
| <b>Interface State</b>       | Enabled                     |

9. Edit port 2 (router2) interface.  
10. Set the following information and select **OK**.

|                              |                                                |
|------------------------------|------------------------------------------------|
| <b>Alias</b>                 | router2                                        |
| <b>IP/Network Mask</b>       | 10.14.201.104/255.255.255.0                    |
| <b>Administrative Access</b> | HTTPS SSH PING                                 |
| <b>Comments</b>              | Link to R&D network & Internet through Router2 |
| <b>Interface State</b>       | Enabled                                        |

11. Edit port 3 (router3) interface.  
12. Set the following information and select **OK**.

|                              |                                                  |
|------------------------------|--------------------------------------------------|
| <b>Alias</b>                 | router3                                          |
| <b>IP/Network Mask</b>       | 10.14.301.104/255.255.255.0                      |
| <b>Administrative Access</b> | HTTPS SSH PING                                   |
| <b>Comments</b>              | Link to R&D network and Internet through Router3 |
| <b>Interface State</b>       | Enabled                                          |

### To configure Router4 system information - CLI

```

config system global
 set hostname Router4
end
config router static
 edit 1
 set device "port2"
 set distance 45
 set gateway 10.14.201.102
 next
 edit 2
 set device "port3"
 set distance 45
 set gateway 10.14.202.103
 end
end
config system interface
 edit port1
 set alias internal
 set ip 10.14.101.104/255.255.255.0
 set allowaccess https ssh ping
 set description "Internal sales network"
 next
 edit port2
 set alias router2
 set allowaccess https ssh ping
 set ip 10.14.201.104/255.255.255.0
 set description "Link to R&D network & Internet through Router2"
 next
 edit port3
 set alias router3
 set ip 10.14.202.104/255.255.255.0
 set allowaccess https ssh ping
 set description "Link to R&D network & Internet through Router2"
 end
end
end

```

### Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

For each FortiGate unit, the following steps will be taken:

- Configure RIP version used
- Redistribute static networks
- Add networks serviced by RIP
- Add interfaces that support RIP on the FortiGate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures. Repeat the procedures once for each FortiGate unit.

### Configure RIP settings on Router1 and Router4 - web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**. Leave the other advanced options at their default values.
4. Under **Networks**, add the following networks:
  - 10.11.0.0/255.255.0.0
  - 10.12.0.0/255.255.0.0
  - 10.14.0.0/255.255.0.0
  - 172.20.120.0/255.255.255.0
6. Under **Interfaces**, select **Create New** and set the following information:

|                        |                  |
|------------------------|------------------|
| <b>Interface</b>       | port1 (internal) |
| <b>Passive</b>         | disabled         |
| <b>Authentication</b>  | None             |
| <b>Send Version</b>    | Both             |
| <b>Receive Version</b> | Both             |

7. Under **Interfaces** select **Create New** and set the following information:

|                        |                 |
|------------------------|-----------------|
| <b>Interface</b>       | port2 (router2) |
| <b>Passive</b>         | disabled        |
| <b>Authentication</b>  | None            |
| <b>Send Version</b>    | Both            |
| <b>Receive Version</b> | Both            |

8. Under **Interfaces**, select **Create New** and set the following information:

|                  |                 |
|------------------|-----------------|
| <b>Interface</b> | port3 (router3) |
| <b>Passive</b>   | disabled        |

|                        |      |
|------------------------|------|
| <b>Authentication</b>  | None |
| <b>Send Version</b>    | Both |
| <b>Receive Version</b> | Both |

### Configure RIP settings on Router1 and Router4 - CLI

```

config router rip
 set version 2
 config interface
 edit "port1"
 set receive-version 1 2
 set send-version 1 2
 next
 edit "port2"
 set receive-version 1 2
 set send-version 1 2
 next
 edit "port3"
 set receive-version 1 2
 set send-version 1 2
 end
 config network
 edit 1
 set prefix 10.11.0.0 255.255.0.0
 next
 edit 2
 set prefix 10.12.0.0 255.255.0.0
 next
 edit 3
 set prefix 10.14.0.0 255.255.0.0
 next
 edit 4
 set prefix 172.20.120.0 255.255.255.0
 end
 config redistribute "static"
 set status enable
 end
end

```

### Configure RIP settings on Router2 and Router3 - web-based manager

1. Go to **Network > RIP**.
2. Select **2** for **RIP**.
3. In **Advanced Options**, under **Redistribute** enable **Static**. Leave the other advanced options at their default values.
4. Under **Networks**, add the following networks:
  - 10.11.0.0/255.255.0.0
  - 10.12.0.0/255.255.0.0
  - 10.14.0.0/255.255.0.0
  - 172.20.120.0/255.255.255.0

6. Under **Interfaces**, select **Create New** and set the following information:

|                        |                  |
|------------------------|------------------|
| <b>Interface</b>       | port1 (internal) |
| <b>Passive</b>         | disabled         |
| <b>Authentication</b>  | None             |
| <b>Send Version</b>    | Both             |
| <b>Receive Version</b> | Both             |

7. Under **Interfaces**, select **Create New** and set the following information:

|                        |                 |
|------------------------|-----------------|
| <b>Interface</b>       | port2 (router1) |
| <b>Passive</b>         | disabled        |
| <b>Authentication</b>  | None            |
| <b>Send Version</b>    | Both            |
| <b>Receive Version</b> | Both            |

8. Under **Interfaces**, select **Create New** and set the following information:

|                        |                 |
|------------------------|-----------------|
| <b>Interface</b>       | port3 (router4) |
| <b>Passive</b>         | disabled        |
| <b>Authentication</b>  | None            |
| <b>Send Version</b>    | Both            |
| <b>Receive Version</b> | Both            |

9. Under **Interfaces**, select **Create New** and set the following information:

|                        |             |
|------------------------|-------------|
| <b>Interface</b>       | port4 (ISP) |
| <b>Passive</b>         | disabled    |
| <b>Authentication</b>  | None        |
| <b>Send Version</b>    | Both        |
| <b>Receive Version</b> | Both        |

### Configure RIP settings on Router2 and Router3 - web-based manager

```
config router rip
set version 2
```

```

config interface
 edit "port1"
 set receive-version 1 2
 set send-version 1 2
 next
 edit "port2"
 set receive-version 1 2
 set send-version 1 2
 next
 edit "port3"
 set receive-version 1 2
 set send-version 1 2
 end
 edit "port4"
 set receive-version 1 2
 set send-version 1 2
 end
config network
 edit 1
 set prefix 10.11.0.0 255.255.0.0
 next
 edit 2
 set prefix 10.12.0.0 255.255.0.0
 next
 edit 3
 set prefix 10.14.0.0 255.255.0.0
 next
 edit 4
 set prefix 172.20.120.0 255.255.255.0
 end
config redistribute "static"
 set status enable
end
end

```

## Configuring other networking devices

In this example, there are two groups of other devices on the the network: internal devices and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers, and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise, there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate Router2 and Router3 connect to. You need to contact your ISP and ensure they have your information for your network, such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

## Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the Internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult [Simple RIP example on page 2534](#).

### IPsec auto discovery support

The following routing settings are available in the CLI to support IPsec auto discovery. They are designed for:

- Supporting the RIPng (RIP next generation) network command
- Limiting the maximum metric allowed to output for RIPng
- Fix NSM missing kernel address update information

The actual new settings are:

```
config router rip
 set max-out-metric <integer value 1 - 15>
end

config router ripng
 set max-out-metric <integer value 1 - 15>
end

config router ripng
 config network
 edit <ID # of network>
 set prefix <IPv6 prefix>
 end
 end
```

## RIPng: RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network, allowing it to reach the Internet at all times.

### Network layout and assumptions

#### Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network, allowing it to reach the Internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

Where possible in this example, the default values will be used (or the most general settings). This is intended to provide an easier configuration that will require less troubleshooting.

In this example, the routers, networks, interfaces used, and IP addresses are as follows.

**RIP example network topology**

| Network | Router  | Interface & alias | IPv6 address           |
|---------|---------|-------------------|------------------------|
| R&D     | Router1 | port1 (internal)  | 2002:A0B:6565:0:0:0:0  |
|         |         | port2 (ISP)       | 2002:AC14:7865:0:0:0:0 |
|         | Router2 | port1 (internal)  | 2002:A0B:6566:0:0:0:0  |
|         |         | port2 (ISP)       | 2002:AC14:7866:0:0:0:0 |

**Network topology for the IPV6 RIPng example**

**Assumptions**

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT operating mode, with VDOMs disabled.

- All FortiGate units have interfaces labeled port1 and port2, as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices support IPv6 and are running RIPng.

## Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

### To configure system information on Router1 - web-based manager

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter "Router1".
4. Go to **System > Config > Features**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information and select **OK**.

|                              |                      |
|------------------------------|----------------------|
| <b>Alias</b>                 | internal             |
| <b>IP/Network Mask</b>       | 2002:A0B:6565::/0    |
| <b>Administrative Access</b> | HTTPS SSH PING       |
| <b>Description</b>           | Internal RnD network |
| <b>Administrative Status</b> | Up                   |

9. Edit port2 (ISP) interface.
10. Set the following information and select **OK**.

|                              |                    |
|------------------------------|--------------------|
| <b>Alias</b>                 | ISP                |
| <b>IP/Network Mask</b>       | 2002:AC14:7865::/0 |
| <b>Administrative Access</b> | HTTPS SSH PING     |
| <b>Description</b>           | ISP and Internet   |
| <b>Administrative Status</b> | Up                 |

### To configure system information on Router1 - CLI

```
config system global
 set hostname Router1
 set gui-ipv6 enable
end
config system interface
 edit port1
 set alias internal
```

```

 set allowaccess https ping ssh
 set description "Internal RnD network"
 config ipv6
 set ip6-address 2002:a0b:6565::/0
 end
 next
 edit port2
 set alias ISP
 set allowaccess https ping ssh
 set description "ISP and Internet"
 config ipv6
 set ip6-address 2002:AC14:7865::
 end
 end
end

```

### To configure system information on Router2 - web-based manager

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Config > Features**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information and select **OK**.

|                              |                      |
|------------------------------|----------------------|
| <b>Alias</b>                 | internal             |
| <b>IP/Network Mask</b>       | 2002:A0B:6566::/0    |
| <b>Administrative Access</b> | HTTPS SSH PING       |
| <b>Description</b>           | Internal RnD network |
| <b>Administrative Status</b> | Up                   |

9. Edit port2 (ISP) interface.
10. Set the following information and select **OK**.

|                              |                    |
|------------------------------|--------------------|
| <b>Alias</b>                 | ISP                |
| <b>IP/Network Mask</b>       | 2002:AC14:7866::/0 |
| <b>Administrative Access</b> | HTTPS SSH PING     |
| <b>Description</b>           | ISP and Internet   |
| <b>Administrative Status</b> | Up                 |

### To configure system information on Router2 - CLI

```
config system global
```

```
set hostname Router2
set gui-ipv6 enable
end
config system interface
edit port1
set alias internal
set allowaccess https ping ssh
set description "Internal RnD network"
config ipv6
set ip6-address 2002:a0b:6566::/0
end
next
edit port2
set alias ISP
set allowaccess https ping ssh
set description "ISP and Internet"
config ipv6
set ip6-address 2002:AC14:7866::
end
end
```

## Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include: the internal network and the ISP network. There is no redistribution and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

### To configure RIPng on Router1 - CLI

```
config router ripng
config interface
edit port1
next
edit port2
end
config neighbor
edit 1
set interface port1
set ipv6 2002:a0b:6566::/0
next
edit 2
set interface port2
set ipv6 2002:AC14:7805::/0
end
```

### To configure RIPng on Router2 - CLI

```
config router ripng
config interface
```

```

edit port1
next
edit port2
end
config neighbor
edit 1
set interface port1
set ipv6 2002:a0b:6565::/0
next
edit 2
set interface port2
set ipv6 2002:AC14:7805::/0
end

```

## Configuring other network devices

The other devices on the internal network all support IPv6 and are running RIPng, where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information, such as IPv6 addresses.

## Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

For troubleshooting problems with RIP, see [RIPng: RIP and IPv6 on page 2550](#).

## Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems:

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit:

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table:

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous `diagnose ipv6 route list` command, but it is presented in a format that is easier to read.

```
get router info6 rip interface external
```

View the brief output on the RIP information for the interface listed. This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

## OSPF

This section describes Open Shortest Path First (OSPF) routing.

### OSPF background and concepts

Open Shortest Path First (OSPF) is a link-state interior routing protocol that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP, because BGP can communicate between ASs

#### Background

OSPF version 2 (OSPFv2) was defined in 1998 in [RFC 2328](#). OSPF was designed to support classless IP addressing and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPFv2 are included in OSPF version 3 (OSPFv3), defined in 2008 in [RFC 5340](#). OSPFv3 includes support for IPv6 addressing, where OSPFv2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds, has converged network traffic successfully without any networking loops. Also, OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

#### The parts and terminology of OSPF

The parts and terminology of OSPF include the following sections.

#### OSPFv3 and IPv6

OSPF version 3 (OSPFv3) includes support for IPv6, configurable from the CLI only. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in [RFC 2740](#). Likewise, the router ID and area ID are in the same format as OSPFv2.

For IPv6, the main difference in OSPFv3 is that rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to the interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
 config area
 edit 0.0.0.0
 next
end
config ospf6-interface
 edit "tunnel"
 set interface "to_FGT300A-7"
next
 edit "internal_lan"
 set interface "port1"
next
 set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, and neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

## Router ID

In OSPF, each router has a unique 32-bit number that is called its router ID. Often, this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However, some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea not to use an IP address for the router ID that is already in use on the router. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused about which number you are looking at. It is a good idea to use as many of the area's numbers as possible. For example, if you have 15 routers in area 0.0.0.0, they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10.

You can manually set the router ID on your FortiGate unit:

### To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. For **Router ID**, enter 0.0.1.1.
3. Select **Apply**.

### To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
 set router-id 0.0.1.1
end
```

## Adjacency

In an OSPF routing network, an OSPF router sends out OSPF hello packets when it boots up, to try to find any neighbours (routers that have access to the same network as the router booting up). Once neighbors are discovered and Hello packets are exchanged, updates are sent and the link state databases of both neighbors are synchronized. At this point, these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met:

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The hello interval and the dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

### Adjacency and neighbors

Neighbor routers can be in a two-way state, and not be adjacent. Adjacent routers normally have a neighbor state of FULL. Neighbors only exchange hello packets and do not exchange routing updates. Adjacent routers

exchange LSAs (LSDB information) as well as hello packets. A good example of an adjacent pair of routers is the designated router (DR) and backup designated router (BDR).

You can check on the state of an OSPF neighbor using the CLI `get router info ospf neighbor all` command. For more information, see [OSPF background and concepts on page 2557](#).

### Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes.

If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates, it would flood the network.

Also, it is better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays, while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent.

The backup designated router (BDR) also has this information in case the DR goes offline.

### Designated router and backup router

In OSPF, a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all of the initial contact and other routing administration traffic. Having only one router do all of this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process does not have many rules, but the exceptions can become complex.

### Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may have only a couple of routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic, but to a lesser extent than on a large network. Also, your network topology will be ready whenever you choose to expand your network.

### DR and BDR election

An election chooses DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers, where the highest priority becomes the DR and the second highest becomes the BDR. To

resolve any ties, the router with the highest router ID wins. For example, a router with a router ID of 192.168.0.1 would win over a router with a router ID of 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes online after the election, it must wait until the DR and BDR go offline before it becomes the DR.

If the original DR goes offline, but is then available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF DR or BDR called `ospf_DR` on the network, you need to raise the priority of the router to a very high number, such as 250 out of 255. This will ensure the interface has a chance to be a DR, but will not guarantee that it will be one. To help ensure it becomes a DR, you should give the interface a low numbered IP address, such as 10.1.1.1 instead of 192.168.1.1 (but that is not part of this example). Enter the following command:

```
config router ospf
 config ospf-interface
 edit "ospf_DR"
 set priority 250
 end
 end
```

## Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

If there are two or more routers that are viable within an area, there will always be a designated router (DR) and a backup designated router (BDR). For more information about these router roles, see [Designated router and backup router on page 2559](#).

Defining a private OSPF area involves the following:

- Assigning a 32-bit number to the area that is unique on your network
- Defining the characteristics of one or more OSPF areas
- Creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- Adjusting the settings of OSPF-enabled interfaces, if required

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF areas:

- [Backbone area](#)
- [Stub area](#)
- [NSSA](#)
- [Regular area](#)

## Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, and possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason, the backbone not only has to connect to all other areas in the network, but also has to be uninterrupted in order to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

## Stub area

A stub area is an OSPF area that receives no outside routes advertised into it. All routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment cannot handle routing large amounts of traffic passing through, or if there are other reasons to prevent outside traffic, such as security. For example, most organizations do not want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally does not make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

## NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to using only the default route for internal routing.

## Regular area

A regular area is what all the other ASs are, all the non-backbone, non-stub, and non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

## Authentication

In the OSPF packet header, there are two authentication-related fields: AuType and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

## Null authentication

Null authentication indicates there is no authentication being used. In this case, the 16-byte authentication field is not checked, and can be any value. However, checksumming is still used to locate errors. On your FortiGate, this is the `none` option for authentication.

## Simple password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use for this type of authentication is to prevent routers from accidentally

joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

### Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear. A packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic, the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example, to create an OSPF interface called `Accounting` on the `port1` interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of `"ospf_test"`, enter the command:

```
config router ospf
 config ospf-interface
 edit Accounting
 set interface port1
 set network-type broadcast
 set hello-interval 10
 set dead-interval 40
 set authentication text
 set authentication-key "ospf_test"
 end
 end
```

### Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered, the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time other routers will wait before declaring a neighbor dead (offline). It is very important to set a reasonable dead interval. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic.

FortiOS also supports OSPF fast-hello, which provides a way to send multiple hello packets per second. This is achieved by setting a dead-interval to one second. The hello-multiplier, which can be any number between 4 and 10, determines the number of hello packets that will be sent every second. The CLI syntax for OSPF fast-hello is as follows:

```
config ospf-interface
 edit ospf1
 set interface port1
 set network-type broadcast
```

```

 set dead-interval 1
 set hello-multiplier 4
 end

```

## Access lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them. An access list essentially makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example, if you want all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found, the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. It also eases troubleshooting because if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols, you will need to use `access-list6`, the IPv6 version of access list. The only difference is that `access-list6` uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of 10.10.10.10 and 11.11.11.11, enter the command:

```

config router access-list
 edit test_list
 config rule
 edit 1
 set prefix 10.10.10.10 255.255.255.255
 set action allow
 set exact-match enable
 next
 edit 2
 set prefix 11.11.11.11 255.255.255.255
 set action allow
 set exact-match enable
 end
 end
 end
end

```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the `access-list6` command as follows:

```

config router access-list6
 edit test_list_ip6
 config rule
 edit 1
 set prefix6 2002:A0A:A0A:0:0:0:0:0/48
 set action deny
 next
 edit 2
 set prefix6 2002:B0B:B0B:0:0:0:0:0/48
 end
 end
 end
end

```

```
 set action deny
 end
```

To use an `access_list`, you must call it from a routing protocol such as RIP. The following example uses the `access_list` from the earlier example called `test_list` to match routes coming in on the `port1` interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following command:

```
config router ospf
 config distribute-list
 edit 5
 set access-list test_list
 set protocol connected
 end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 cannot be exactly matched with an access-list. A prefix-list must be used for this purpose.

## How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers (ABR). A group of contiguous networks form an area. An ABR links one or more areas to the OSPF network backbone (area ID 0). For more information, see [Dynamic routing overview on page 2503](#).

OSPF is an interior routing protocol. It includes a backbone AS and possibly additional ASs. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that it uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP and BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works include:

- [OSPF router discovery](#)
- [How OSPF works on FortiGate units](#)
- [External routes](#)
- [Link state database and route updates](#)
- [OSPF packets](#)

## OSPF router discovery

OSPF-enabled routers generate link state advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the following steps occur:

1. When OSPF routers come online, they send out hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, they generally become adjacent. Adjacent routers can exchange routing updates. For more information, see [Adjacency on page 2558](#).
3. A DR and BDR are elected from the available routers using priority settings and router ID. See [Designated router and backup router on page 2559](#), and [OSPF background and concepts on page 2557](#).
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

### How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

### External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination is using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, which are used for OSPF external1 (E1) and OSPF external2 (E2).

#### OSPF E1

In OSPF E1, the destination is outside the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

#### OSPF E2

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, for example, on border routers that have no OSPF portion or where the OSPF routing cost is negligible compared to the external routing cost.

### Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost, essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

## Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through the CLI.

### To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes, including the OSPF external routes. For a shorter list, you can use the `get router info routing-table ospf` command. The letter at the left will be either E1 or E2 for external OSPF routes. The output will look similar to the following, depending on what routes are in your routing table:

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2 0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O 10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

## Link state database and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with link state database (LSDB) updates. External links allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link state updates passed along the network. When there are no more changes required and the network is stable, the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path, which is how fast traffic will get from one point to another.

The path cost, similar to "distance" for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas ([RFC 3509](#)).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- The addresses of networks in the local OSPF area (to which packets are sent directly)
- Routes to OSPF area border routers (to which packets destined for another area are sent)
- Routes to area boundary routers, if the network contains OSPF areas and non-OSPF domains, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

## OSPF route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

Our router gets a new route and needs to decide if it should go in the routing table.

The router has an up-to-date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.

Our router turns the LSDB into an SPF tree using Dijkstra's algorithm. It does not matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

Once the SPF tree has been created and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.

If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can also update their LSDBs. This is vital since all routers on the OSPF area must have the same LSDB.

If there was no change between the LSDB and the SPF tree, no action is taken.

## OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

### OSPF packet

|                             |                       |                      |                        |
|-----------------------------|-----------------------|----------------------|------------------------|
| 1-byte Version field        | 1-byte Type field     | 2-byte Packet length | 3-byte Router ID       |
| 4-byte Area ID              | 2-byte Checksum       | 2-byte Auth Type     | 8-byte Authentication  |
| 4-byte Network Mask         | 2-byte Hello interval | 1-byte Options field | 1-byte Router Priority |
| 4-byte Dead Router interval | 4-byte DR field       | 4-byte BDR field     | 4-byte Neighbor ID     |

The following descriptions summarize the OSPF packet header fields:

**Version field:** The OSPF version number. This specification documents version 2 of the protocol.

**Type field:** There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

**Packet length:** The length of the OSPF protocol packet, in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

**Router ID:** The Router ID of the packet's source.

**Area ID:** A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

**Checksum:** The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure. For some authentication types, the checksum calculation is omitted.

**Auth Type:** Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

**Authentication:** A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the authentication field is not checked and can be any value. When AuType is set to 2 (cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The Authentication data length field indicates how many bytes long the message digest is. The Cryptographic sequence field is a non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

**Network Mask:** The subnet where this packet is valid.

**Hello interval:** The period of time between sending out hello packets. For more information, see [Hello and dead intervals on page 2562](#).

**Options field:** The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF hello packets, database description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single AS.

**Router priority:** The priority, between 0 and 255, that determines which routers become the DR and BDR. For more information, see [Designated router and backup router on page 2559](#).

**Dead router interval:** The period of time when there is no response from a router before it is declared dead. For more information, see [Hello and dead intervals on page 2562](#).

**DR and BDR fields:** The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. For more information, see [Designated router and backup router on page 2559](#).

**Neighbor ID:** The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

## Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the FortiOS Handbook Troubleshooting chapter.

## Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` command. The `exec router clear` command is much more limiting for OSPF than it is for BGP. For more information, see [BGP on page 2598](#).

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

```
execute router clear ospf process
```

## Checking the state of OSPF neighbors

In OSPF, each router sends out link state advertisements to find other routers on its network segment and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI `get router info ospf neighbor all` command to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.0.0.2 1 Full/ - 00:00:39 10.1.1.2 tunnel_wan1
10.0.0.2 1 Full/ - 00:00:34 10.1.1.4 tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

## Passive interface problems

A passive OSPF interface does not send out any updates. This means it cannot be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link state table.

Passive interfaces can cause problems when they are not receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out-of-date link state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however, this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device, and allow it to repopulate the table.

If you cannot make the interface active for some reason, you will have to change your network to fix the “hole” by adding more routers, or changing the relationship between the passive router’s neighbors to provide better coverage.

## Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example, if one router declares a router dead after 45 seconds and another waits for 4 minutes, that difference in time will result in those

two routers being out of synch for that period of time. One will still see the offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval and dead interval periods, so you can compare them easily enough.

## **BFD**

Bidirectional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

## **Authentication issues**

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing and they will not acknowledge a router. This can be a problem if that router connects areas to the backbone, as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. It is possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems since it may be only one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is related to authentication, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

## **DR and BDR election issues**

You can force a particular router to become the DR and BDR by setting its priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all of that traffic.

However, if you set all the other routers so they do not have a chance at being elected (give them a priority of 0), you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. However, if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or perform the other tasks that the DR performs.

The solution to this is to always allow routers to have a chance to be promoted, even if you set their priority to 1. In that case, they will be the last choice but if there are no other candidates, you want that router to become the DR. Most networks will have already alerted you to the equipment problems, so this will be a temporary measure to keep the network traffic moving until you can find and fix the problem and get the real DR back online.

## Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPFv2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and Router2 will be the backup designated router (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections. Instead, Router3 is the Autonomous System Border Router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow and is charged by the amount of traffic. For these reasons, OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. However, the ISP network does have to be added to that router's configuration.

### Network layout and assumptions

There are three FortiGate units acting as OSPFv2 routers on the network: Router1, Router2, and Router3. Router1 will be the DR, and Router 2 the BDR. Router3 is the ASBR that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The head office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

#### Routers, interfaces, and IP addresses for the basic OSPF example network

| Router name           | Interface         | IP address   | Interface is connected to:      |
|-----------------------|-------------------|--------------|---------------------------------|
| <b>Router1 (DR)</b>   | Internal (port1)  | 10.11.101.1  | Head office network and Router2 |
|                       | External (port2)  | 10.11.102.1  | Router3                         |
| <b>Router2 (BDR)</b>  | Internal (port1)  | 10.11.101.2  | Head office network and Router1 |
|                       | External (port2)  | 10.11.103.2  | Router3                         |
|                       | DSL (port3)       | 10.12.101.2  | PPPoE DSL access                |
|                       | Internal1 (port1) | 10.11.102.3  | Router1                         |
| <b>Router3 (ASBR)</b> | Internal2 (port2) | 10.11.103.3  | Router2                         |
|                       | External (port3)  | 172.20.120.3 | ISP's BGP network               |

### Basic OSPF network topology

Note that other subnets can be added to the internal interfaces without changing the configuration.

### Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed and are in NAT operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

### Configuring the FortiGate units

Each FortiGate unit needs the interfaces and basic system information, such as hostname, configured.

This section includes:

- [Configuring Router1](#)
- [Configuring Router2](#)

- [Configuring Router3](#)

## Configuring Router1

Router1 has two interfaces connected to the network: internal (port1) and external (port2). Its host name must be changed to Router1.

### To configure Router1 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router1` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.101.1/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Head office and Router2   |
| <b>Administrative Status</b> | Up                        |

5. Edit port2, set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | External                  |
| <b>IP/Network Mask</b>       | 10.11.102.1/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router3                   |
| <b>Administrative Status</b> | Up                        |

## Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf\_example”. The default gateway will be retrieved from the ISP and the defaults will be used for the rest of the PPPoE settings.

### To configure Router2 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router2` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.101.2/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Head office and Router1   |
| <b>Administrative Status</b> | Up                        |

5. Edit port2, set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | External                  |
| <b>IP/Network Mask</b>       | 10.11.103.2/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router3                   |
| <b>Administrative Status</b> | Up                        |

6. Edit DSL (port3), set the following information and select **OK**.

|                                             |                           |
|---------------------------------------------|---------------------------|
| <b>Alias</b>                                | DSL                       |
| <b>Addressing Mode</b>                      | PPPoE                     |
| <b>Username</b>                             | user1                     |
| <b>Password</b>                             | ospf_example              |
| <b>Unnumbered IP</b>                        | 10.12.101.2/255.255.255.0 |
| <b>Retrieve default gateway from server</b> | Enable                    |
| <b>Administrative Access</b>                | HTTPS SSH PING            |
| <b>Description</b>                          | DSL                       |
| <b>Administrative Status</b>                | Up                        |

### Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network, which has no administration access enabled for security reasons.

#### To configure Router3 interfaces - web-based manager

1. Go to **System > Status > Dashboard**.
2. Next to hostname, select **Change**.

3. Enter a hostname of `Router3` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.102.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router1                   |
| <b>Administrative Status</b> | Up                        |

5. Edit port2, set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | Internal2                 |
| <b>IP/Network Mask</b>       | 10.11.103.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router2                   |
| <b>Administrative Status</b> | Up                        |

6. Edit port3, set the following information and select **OK**.

|                              |                            |
|------------------------------|----------------------------|
| <b>Alias</b>                 | External                   |
| <b>IP/Network Mask</b>       | 172.20.120.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING             |
| <b>Description</b>           | ISP BGP                    |
| <b>Administrative Status</b> | Up                         |

## Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration, there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also, the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- Router ID
- Area
- Network
- Two or three interfaces depending on the router
- Priority for DR (Router1) and BDR (Router2)
- Redistribute for ASBR (Router3)

This section includes:

- [Configuring OSPF on Router1](#)
- [Configuring OSPF on Router2](#)
- [Configuring OSPF on Router3](#)

### Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point. Otherwise, it is a standard OSPF configuration. Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

#### To configure OSPF on Router1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.1` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

|                       |         |
|-----------------------|---------|
| <b>Area</b>           | 0.0.0.0 |
| <b>Type</b>           | Regular |
| <b>Authentication</b> | none    |

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                       |
|-------------------|-----------------------|
| <b>IP/Netmask</b> | 10.11.0.0/255.255.0.0 |
| <b>Area</b>       | 0.0.0.0               |

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |                     |
|-----------------------|---------------------|
| <b>Name</b>           | Router1-Internal-DR |
| <b>Interface</b>      | port1 (Internal)    |
| <b>IP</b>             | 0.0.0.0             |
| <b>Authentication</b> | none                |

| Timers (seconds) |    |
|------------------|----|
| Hello Interval   | 10 |
| Dead Interval    | 40 |

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

| <b>Name</b>           | Router1-External |
|-----------------------|------------------|
| <b>Interface</b>      | port2 (External) |
| <b>IP</b>             | 0.0.0.0          |
| <b>Authentication</b> | none             |
| Timers (seconds)      |                  |
| <b>Hello Interval</b> | 10               |
| <b>Dead Interval</b>  | 40               |

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
 config ospf-interface
 edit Router1-Internal-DR
 set priority 255
 end
```

### To configure OSPF on Router1 - CLI

```
config router ospf
 set router-id 10.11.101.1
 config area
 edit 0.0.0.0
 next
 end
 config network
 edit 1
 set prefix 10.11.0.0/255.255.255.0
 next
 end
 config ospf-interface
 edit "Router1-Internal"
 set interface "port1"
 set priority 255
 next
 edit "Router1-External"
 set interface "port2"
 next
 end
end
```

## Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area and configures the DSL interface slightly differently. Assume this will be a slower connection resulting in the need for longer timers and a higher cost for this route.

Otherwise, it is a standard OSPF configuration.

### To configure OSPF on Router2 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

|                       |         |
|-----------------------|---------|
| <b>Area</b>           | 0.0.0.0 |
| <b>Type</b>           | Regular |
| <b>Authentication</b> | none    |

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                       |
|-------------------|-----------------------|
| <b>IP/Netmask</b> | 10.11.0.0/255.255.0.0 |
| <b>Area</b>       | 0.0.0.0               |

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                         |                  |
|-------------------------|------------------|
| <b>Name</b>             | Router2-Internal |
| <b>Interface</b>        | port1 (Internal) |
| <b>IP</b>               | 0.0.0.0          |
| <b>Authentication</b>   | none             |
| <b>Timers (seconds)</b> |                  |
| <b>Hello Interval</b>   | 10               |
| <b>Dead Interval</b>    |                  |

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                  |                  |
|------------------|------------------|
| <b>Name</b>      | Router2-External |
| <b>Interface</b> | port2 (External) |
| <b>IP</b>        | 0.0.0.0          |

|                       |      |
|-----------------------|------|
| <b>Authentication</b> | none |
|-----------------------|------|

|                         |
|-------------------------|
| <b>Timers (seconds)</b> |
|-------------------------|

|                       |    |
|-----------------------|----|
| <b>Hello Interval</b> | 10 |
|-----------------------|----|

|                      |    |
|----------------------|----|
| <b>Dead Interval</b> | 40 |
|----------------------|----|

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|             |             |
|-------------|-------------|
| <b>Name</b> | Router2-DSL |
|-------------|-------------|

|                  |             |
|------------------|-------------|
| <b>Interface</b> | port3 (DSL) |
|------------------|-------------|

|           |         |
|-----------|---------|
| <b>IP</b> | 0.0.0.0 |
|-----------|---------|

|                       |      |
|-----------------------|------|
| <b>Authentication</b> | none |
|-----------------------|------|

|             |    |
|-------------|----|
| <b>Cost</b> | 50 |
|-------------|----|

|                         |
|-------------------------|
| <b>Timers (seconds)</b> |
|-------------------------|

|                       |    |
|-----------------------|----|
| <b>Hello Interval</b> | 20 |
|-----------------------|----|

|                      |    |
|----------------------|----|
| <b>Dead Interval</b> | 80 |
|----------------------|----|

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
 config ospf-interface
 edit Router2-Internal
 set priority 250
 next
 end
```

### To configure OSPF on Router2 - CLI

```
config router ospf
 set router-id 10.11.101.2
 config area
 edit 0.0.0.0
 next
 end
 config network
 edit 1
 set prefix 10.11.0.0/255.255.0.0
 next
 end
 config ospf-interface
 edit "Router2-Internal"
 set interface "port1"
 set priority 255
 next
```

```

edit "Router2-External"
 set interface "port2"
next
edit "Router2-DSL"
 set interface "port3"
 set cost 50
next
end
end

```

### Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 an ASBR. Also, Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

#### To configure OSPF on Router3 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. Expand **Advanced Options**.
4. In **Redistribute**, set the following information, and select **OK**.

| Route type       | Redistribute | Metric |
|------------------|--------------|--------|
| <b>Connected</b> | Enable       | 15     |
| <b>Static</b>    | Enable       | 15     |
| <b>RIP</b>       | Disable      | n/a    |
| <b>BGP</b>       | Enable       | 5      |

5. In **Areas**, select **Create New**, set the following information, and select **OK**.

|                       |         |
|-----------------------|---------|
| <b>Area</b>           | 0.0.0.0 |
| <b>Type</b>           | Regular |
| <b>Authentication</b> | none    |

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                       |
|-------------------|-----------------------|
| <b>IP/Netmask</b> | 10.11.0.0/255.255.0.0 |
| <b>Area</b>       | 0.0.0.0               |

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                         |                  |
|-------------------------|------------------|
| <b>Name</b>             | Router3-Internal |
| <b>Interface</b>        | port1 (Internal) |
| <b>IP</b>               | 0.0.0.0          |
| <b>Authentication</b>   | none             |
| <b>Timers (seconds)</b> |                  |
| <b>Hello Interval</b>   | 10               |
| <b>Dead Interval</b>    | 40               |

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                         |                   |
|-------------------------|-------------------|
| <b>Name</b>             | Router3-Internal2 |
| <b>Interface</b>        | port2 (Internal2) |
| <b>IP</b>               | 0.0.0.0           |
| <b>Authentication</b>   | none              |
| <b>Timers (seconds)</b> |                   |
| <b>Hello Interval</b>   | 10                |
| <b>Dead Interval</b>    | 40                |

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                         |                 |
|-------------------------|-----------------|
| <b>Name</b>             | Router3-ISP-BGP |
| <b>Interface</b>        | port3 (ISP-BGP) |
| <b>IP</b>               | 0.0.0.0         |
| <b>Authentication</b>   | none            |
| <b>Cost</b>             | 2               |
| <b>Timers (seconds)</b> |                 |
| <b>Hello Interval</b>   | 20              |
| <b>Dead Interval</b>    | 80              |

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
```

```
 config ospf-interface
 edit Router3-Internal
 set priority 250
 next
end
```

### To configure OSPF on Router3 - CLI

```
config router ospf
 set router-id 10.11.102.3
 config area
 edit 0.0.0.0
 next
 end
 config network
 edit 1
 set prefix 10.11.0.0/255.255.255.0
 next
 edit 2
 set prefix 172.20.120.0/255.255.255.0
 next
 end
 config ospf-interface
 edit "Router3-Internal"
 set interface "port1"
 set priority 255
 next
 edit "Router3-External"
 set interface "port2"
 next
 edit "Router3-ISP-BGP"
 set interface "port3"
 set cost 2
 next
 end
end
```

## Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified about the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

## Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity and testing the OSPF routing.

To test the network connectivity, use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in [Basic OSPF example on page 2571](#).

## Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas would not be this small, and if they were, the areas would be combined into one larger area. However, the stub area services the accounting department whose members are very sensitive about their network and do not want their network information broadcasted through the rest of the company. The backbone area contains the bulk of the company's network devices. The regular area was established for various reasons, such as hosting the company servers in a separate area with extra security.

One area is a small stub area that has no independent Internet connection, and has only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

### Network layout and assumptions

There are four FortiGate units in this network topology, which are acting as OSPF routers:

## Advanced inter-area OSPF network topology

Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also, in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected but they are not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

### Routers, areas, interfaces, and IP addresses for advanced OSPF network

| Router name          | Area number and type                      | Interface         | IP address   |
|----------------------|-------------------------------------------|-------------------|--------------|
| <b>Router1 (DR)</b>  | 1.1.1.1 - stub area<br>(Accounting)       | port1 (internal)  | 10.11.101.1  |
|                      |                                           | port2 (external1) | 10.11.110.1  |
| <b>Router2 (BDR)</b> | 0.0.0.0 - backbone area<br>( R&D Network) | port1 (internal)  | 10.11.102.2  |
|                      |                                           | port2 (external1) | 10.11.110.2  |
|                      |                                           | port3 (external2) | 10.11.111.2  |
| <b>Router3 (DR)</b>  | 0.0.0.0 - backbone area<br>(R&D Network)  | port1 (internal)  | 10.11.103.3  |
|                      |                                           | port2 (external1) | 10.11.110.3  |
|                      |                                           | port3 (external2) | 10.11.111.3  |
| <b>Router4 (DR)</b>  | 2.2.2.2 - regular area<br>(Network Admin) | port1 (internal)  | 10.11.104.4  |
|                      |                                           | port2 (external2) | 10.11.111.4  |
|                      |                                           | port3 (ISP)       | 172.20.120.4 |

Note that other subnets can be added to the internal interfaces without changing the configuration.

### Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed and are in NAT operation mode.
- During configuration, if settings are not directly referred to, they will be left at the default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network but do not affect this configuration.

### Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers. These configurations include multiple interface settings and the hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only the Router3 (the DR) configuration will be given, with notes indicating Router2's (the BDR) IP addresses.

Configuring the FortiGate units include:

- [Configuring Router1](#)
- [Configuring Router2](#)
- [Configuring Router3](#)
- [Configuring Router4](#)

## Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

### To configure Router1 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router1` and select **OK**.
4. Go to **Network > Interfaces** edit port1, set the following information, and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.101.1/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Accounting network        |
| <b>Administrative Status</b> | Up                        |

5. Edit port2, set the following information and select **OK**.

|                              |                               |
|------------------------------|-------------------------------|
| <b>Alias</b>                 | External1                     |
| <b>IP/Network Mask</b>       | 10.11.110.1/255.255.255.0     |
| <b>Administrative Access</b> | HTTPS SSH PING                |
| <b>Description</b>           | Backbone network and Internet |
| <b>Administrative Status</b> | Up                            |

## Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured: one to the internal network and two to Router3 for redundancy.

### To configure Router2 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router2` and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.102.2/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Internal RnD network      |
| <b>Administrative Status</b> | Up                        |

5. Edit port2 (external1), set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | external1                 |
| <b>IP/Network Mask</b>       | 10.11.110.2/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router3 first connection  |
| <b>Administrative Status</b> | Up                        |

6. Edit port3 (external2), set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | external2                 |
| <b>IP/Network Mask</b>       | 10.11.111.2/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router3 second connection |
| <b>Administrative Status</b> | Up                        |

### Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

#### To configure Router3 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3` and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

|              |          |
|--------------|----------|
| <b>Alias</b> | internal |
|--------------|----------|

|                              |                           |
|------------------------------|---------------------------|
| <b>IP/Network Mask</b>       | 10.11.103.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Internal RnD network      |
| <b>Administrative Status</b> | Up                        |

5. Edit port2 (external1), set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | external1                 |
| <b>IP/Network Mask</b>       | 10.11.110.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router2 first connection  |
| <b>Administrative Status</b> | Up                        |

6. Edit port3 (external2), set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | external2                 |
| <b>IP/Network Mask</b>       | 10.11.111.3/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Router2 second connection |
| <b>Administrative Status</b> | Up                        |

## Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides Internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

### To configure Router4 interfaces - web-based manager

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router4` and select **OK**.
4. Go to **Network > Interfaces**.
5. Edit port1 (internal).
6. Set the following information and select **OK**.

|                              |                           |
|------------------------------|---------------------------|
| <b>Alias</b>                 | internal                  |
| <b>IP/Network Mask</b>       | 10.11.101.4/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING            |
| <b>Description</b>           | Accounting network        |
| <b>Administrative Status</b> | Up                        |

7. Edit port2 (external2).
8. Set the following information and select **OK**.

|                              |                                 |
|------------------------------|---------------------------------|
| <b>Alias</b>                 | external2                       |
| <b>IP/Network Mask</b>       | 10.11.110.4/255.255.255.0       |
| <b>Administrative Access</b> | HTTPS SSH PING                  |
| <b>Description</b>           | Backbone and Accounting network |
| <b>Administrative Status</b> | Up                              |

9. Edit port3 (ISP).
10. Set the following information and select **OK**.

|                              |                            |
|------------------------------|----------------------------|
| <b>Alias</b>                 | ISP                        |
| <b>IP/Network Mask</b>       | 172.20.120.4/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING             |
| <b>Description</b>           | ISP and Internet           |
| <b>Administrative Status</b> | Up                         |

## Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also, each area needs to be configured as each respective type of area: stub, backbone, or regular. This affects how routes are advertised into the area.

### To configure OSPF on Router1 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.101.1 for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

|                |         |
|----------------|---------|
| Area           | 1.1.1.1 |
| Type           | Stub    |
| Authentication | None    |

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

|            |                           |
|------------|---------------------------|
| IP/Netmask | 10.11.101.0/255.255.255.0 |
| Area       | 1.1.1.1                   |

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                |                  |
|----------------|------------------|
| Name           | Accounting       |
| Interface      | port1 (internal) |
| IP             | 10.11.101.1      |
| Authentication | None             |

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                |                   |
|----------------|-------------------|
| Name           | Backbone1         |
| Interface      | port2 (external1) |
| IP             | 10.11.110.1       |
| Authentication | None              |

### To configure OSPF on Router2 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.102.2 for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

|                |         |
|----------------|---------|
| Area           | 0.0.0.0 |
| Type           | Regular |
| Authentication | None    |

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

|            |                           |
|------------|---------------------------|
| IP/Netmask | 10.11.102.2/255.255.255.0 |
| Area       | 0.0.0.0                   |

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                           |
|-------------------|---------------------------|
| <b>IP/Netmask</b> | 10.11.110.2/255.255.255.0 |
| <b>Area</b>       | 0.0.0.0                   |

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                           |
|-------------------|---------------------------|
| <b>IP/Netmask</b> | 10.11.111.2/255.255.255.0 |
| <b>Area</b>       | 0.0.0.0                   |

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |                  |
|-----------------------|------------------|
| <b>Name</b>           | RnD network      |
| <b>Interface</b>      | port1 (internal) |
| <b>IP</b>             | 10.11.102.2      |
| <b>Authentication</b> | None             |

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |                   |
|-----------------------|-------------------|
| <b>Name</b>           | Backbone1         |
| <b>Interface</b>      | port2 (external1) |
| <b>IP</b>             | 10.11.110.2       |
| <b>Authentication</b> | None              |

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |                   |
|-----------------------|-------------------|
| <b>Name</b>           | Backbone2         |
| <b>Interface</b>      | port3 (external2) |
| <b>IP</b>             | 10.11.111.2       |
| <b>Authentication</b> | None              |

#### To configure OSPF on Router3 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.103.3 for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

|             |         |
|-------------|---------|
| <b>Area</b> | 0.0.0.0 |
|-------------|---------|

|                |         |
|----------------|---------|
| Type           | Regular |
| Authentication | None    |

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

|            |                           |
|------------|---------------------------|
| IP/Netmask | 10.11.102.3/255.255.255.0 |
| Area       | 0.0.0.0                   |

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

|            |                           |
|------------|---------------------------|
| IP/Netmask | 10.11.110.3/255.255.255.0 |
| Area       | 0.0.0.0                   |

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

|            |                           |
|------------|---------------------------|
| IP/Netmask | 10.11.111.3/255.255.255.0 |
| Area       | 0.0.0.0                   |

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                |                  |
|----------------|------------------|
| Name           | RnD network      |
| Interface      | port1 (internal) |
| IP             | 10.11.103.3      |
| Authentication | None             |

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                |                   |
|----------------|-------------------|
| Name           | Backbone1         |
| Interface      | port2 (external1) |
| IP             | 10.11.110.3       |
| Authentication | None              |

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|           |                   |
|-----------|-------------------|
| Name      | Backbone2         |
| Interface | port3 (external2) |

|                       |             |
|-----------------------|-------------|
| <b>IP</b>             | 10.11.111.3 |
| <b>Authentication</b> | None        |

#### To configure OSPF on Router4 - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.104.4 for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New**.
4. Set the following information and select **OK**.

|                       |         |
|-----------------------|---------|
| <b>Area</b>           | 2.2.2.2 |
| <b>Type</b>           | Regular |
| <b>Authentication</b> | None    |

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                           |
|-------------------|---------------------------|
| <b>IP/Netmask</b> | 10.11.104.0/255.255.255.0 |
| <b>Area</b>       | 0.0.0.0                   |

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                           |
|-------------------|---------------------------|
| <b>IP/Netmask</b> | 10.11.111.0/255.255.255.0 |
| <b>Area</b>       | 0.0.0.0                   |

7. In **Networks**, select **Create New**, set the following information, and select **OK**.

|                   |                            |
|-------------------|----------------------------|
| <b>IP/Netmask</b> | 172.20.120.0/255.255.255.0 |
| <b>Area</b>       | 0.0.0.0                    |

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |                       |
|-----------------------|-----------------------|
| <b>Name</b>           | Network Admin network |
| <b>Interface</b>      | port1 (internal)      |
| <b>IP</b>             | 10.11.104.4           |
| <b>Authentication</b> | None                  |

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|             |           |
|-------------|-----------|
| <b>Name</b> | Backbone2 |
|-------------|-----------|

|                       |                   |
|-----------------------|-------------------|
| <b>Interface</b>      | port2 (external2) |
| <b>IP</b>             | 10.11.111.4       |
| <b>Authentication</b> | None              |

10. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

|                       |              |
|-----------------------|--------------|
| <b>Name</b>           | ISP          |
| <b>Interface</b>      | port3 (ISP)  |
| <b>IP</b>             | 172.20.120.4 |
| <b>Authentication</b> | None         |

### Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

### Testing network configuration

There are two main areas to test in this network configuration: network connectivity and OSPF routing.

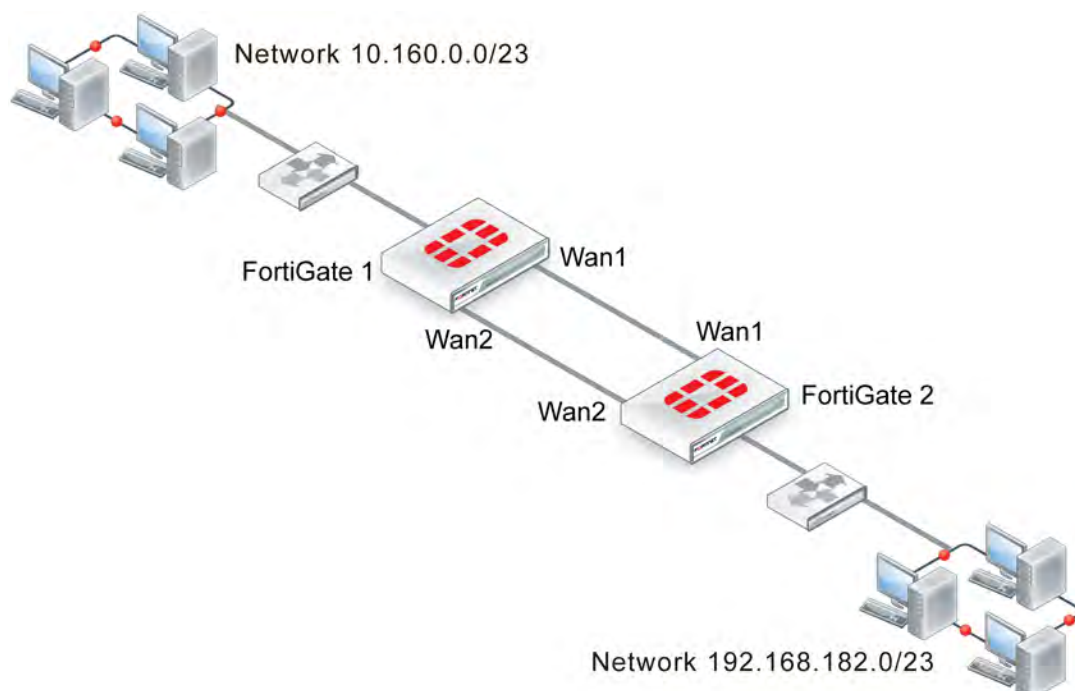

To test network connectivity, see if computers on the Accounting or R&D networks can access the Internet. If you need troubleshooting network connectivity, see the FortiOS Handbook Troubleshooting chapter.

To test OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see [Advanced inter-area OSPF example on page 2583](#).

### Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.

FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

#### FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

#### FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

## Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

### On both FortiGate units:

```
config router ospf
 config ospf-interface
 edit "WAN2_higher_cost"
 set cost 200
 set interface "wan2"
 end
```

Now, both FortiGate units use only the WAN1 route:

### FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

### FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

### LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)
LS age: 81
Options: 0x2 (*|-|-|-|-|E|-)
Flags: 0x0
LS Type: router-LSA
Link State ID: 10.1.1.1
Advertising Router: 10.1.1.1
LS Seq Number: 8000000b
Checksum: 0xe637
Length: 60
Number of Links: 3

Link connected to: Stub Network
(Link ID) Network/subnet number: 10.160.0.0
(Link Data) Network Mask: 255.255.254.0
Number of TOS metrics: 0
TOS 0 Metric: 10
Link connected to: a Transit Network
(Link ID) Designated Router address: 10.183.0.187
(Link Data) Router Interface address: 10.183.0.57
Number of TOS metrics: 0
TOS 0 Metric: 200

Link connected to: a Transit Network
(Link ID) Designated Router address: 10.182.0.57
(Link Data) Router Interface address: 10.182.0.57
```

```

Number of TOS metrics: 0
TOS 0 Metric: 10

LS age: 83
Options: 0x2 (*|---|E|)
Flags: 0x2 : ASBR
LS Type: router-LSA
Link State ID: 10.2.2.2
Advertising Router: 10.2.2.2
LS Seq Number: 8000000e
Checksum: 0xfc9b
Length: 60
 Number of Links: 3

 Link connected to: Stub Network
 (Link ID) Network/subnet number: 192.168.182.0
 (Link Data) Network Mask: 255.255.254.0
 Number of TOS metrics: 0
 TOS 0 Metric: 10

 Link connected to: a Transit Network
 (Link ID) Designated Router address: 10.183.0.187
 (Link Data) Router Interface address: 10.183.0.187
 Number of TOS metrics: 0
 TOS 0 Metric: 200

 Link connected to: a Transit Network
 (Link ID) Designated Router address: 10.182.0.57
 (Link Data) Router Interface address: 10.182.0.187
 Number of TOS metrics: 0
 TOS 0 Metric: 10

```

## Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

### FortiGate 1:

```

FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06

```

### FortiGate 2:

```

FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14

```

The WAN2 interface is now in use on both units.

## BGP

This section describes Border Gateway Protocol (BGP).

### BGP background and concepts

BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

#### Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in [RFC 1771](#). That RFC has since been replaced by [RFC 4271](#). The main benefits of BGP-4 are classless inter-domain routing and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies, and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in [RFC 2858](#) and [RFC 2545](#).

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

#### Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here because they are common to other dynamic routing protocols. When determining your network topology, note that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. For more information about the parts of BGP that are not listed here, see [Dynamic routing overview on page 2503](#).

#### BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4 but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the "6" on the end of the keyword, such as `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the [FortiGate CLI Reference](#).

IPv6 BGP commands include:

```
config router bgp
 set activate6 {enable | disable}
 set allowas-in6 <max_num_AS_integer>
 set allowas-in-enable6 {enable | disable}
 set as-override6 {enable | disable}
 set attribute-unchanged6 [as-path] [med] [next-hop]
```

```

## Role of routers in BGP networks

Dynamic routing has a number of different roles that routers can fill, such as those covered in [Dynamic routing overview on page 2503](#). BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors

### Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers are not treated as BGP routers.

### Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise, these routers will not be seen as peers, but simply as other routers on the network that do not support BGP. Optionally, you can use MD5 authentication to password-protect BGP sessions with those neighbors (see [RFC 2385](#)).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions), using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In the following diagram, Router A is directly connected to five other routers in a network that contains 12 routers. These routers (the ones in the blue circle) are Router A's peers or neighbors.

As a minimum, when configuring BGP neighbors, you must enter their IP address and the AS number (remote-as). This is all of the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
 config neighbor
 edit <neighbor_address_ipv4>
 set activate {enable | disable}
 set advertisement-interval <seconds_integer>
 set allowas-in <max_num_AS_integer>
 set allowas-in-enable {enable | disable}
 set as-override {enable | disable}
 set attribute-unchanged [as-path] [med] [next-hop]
 set bfd {enable | disable}
 set capability-default-originate {enable | disable}
 set capability-dynamic {enable | disable}
 set capability-graceful-restart {enable | disable}
 set capability-orf {both | none | receive | send}
 set capability-route-refresh {enable | disable}
 set connect-timer <seconds_integer>
 set description <text_str>
 set distribute-list-in <access-list-name_str>
 set distribute-list-out <access-list-name_str>
 set dont-capability-negotiate {enable | disable}
 set ebgp-enforce-multihop {enable | disable}
 set ebgp-multihop {enable | disable}
 set ebgp-multihop-ttl <seconds_integer>
 set filter-list-in <aspath-list-name_str>
```

```
set filter-list-out <aspath-list-name_str>
set holdtime-timer <seconds_integer>
set interface <interface-name_str>
set keep-alive-timer <seconds_integer>
set maximum-prefix <prefix_integer>
set maximum-prefix-threshold <percentage_integer>
set maximum-prefix-warning-only {enable | disable}
set next-hop-self {enable | disable}
set passive {enable | disable}
set password <string>
set prefix-list-in <prefix-list-name_str>
set prefix-list-out <prefix-list-name_str>
set remote-as <id_integer>
set remove-private-as {enable | disable}
set retain-stale-time <seconds_integer>
set route-map-in <routemap-name_str>
set route-map-out <routemap-name_str>
set route-reflector-client {enable | disable}
set route-server-client {enable | disable}
set send-community {both | disable | extended | standard}
set shutdown {enable | disable}
set soft-reconfiguration {enable | disable}
set strict-capability-match {enable | disable}
set unsuppress-map <route-map-name_str>
set update-source <interface-name_str>
set weight <weight_integer>
end
end
end
```

## Route reflectors

Route reflectors (RR) in BGP concentrate route updates so other routers only need to talk to the RRs to get all of the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP RRs are defined in [RFC 1966](#).

In a BGP RR configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other RRs and border routers. Only the reflectors need to be configured, not the clients, because the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since RRs are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically do not require RRs. However, RRs are a useful feature for large companies, where their AS may include 100 routers or more. For example, a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. Based on these numbers, updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how RRs can improve the situation when only six routers are involved. The AS without RRs requires 15 sessions between the routers. In the AS with RRs, the two RRs receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster, as well as other RRs, and pass them

on to the border router. The RR configuration requires only six sessions. This example shows a reduction of 60% for the number of required sessions.

### Required sessions within an AS with and without RRs

The BGP commands related to RRs include:

```
config router bgp
 config neighbor
 set route-reflector-client {enable | disable}
 set route-server-client {enable | disable}
 end
end
```

### Confederations

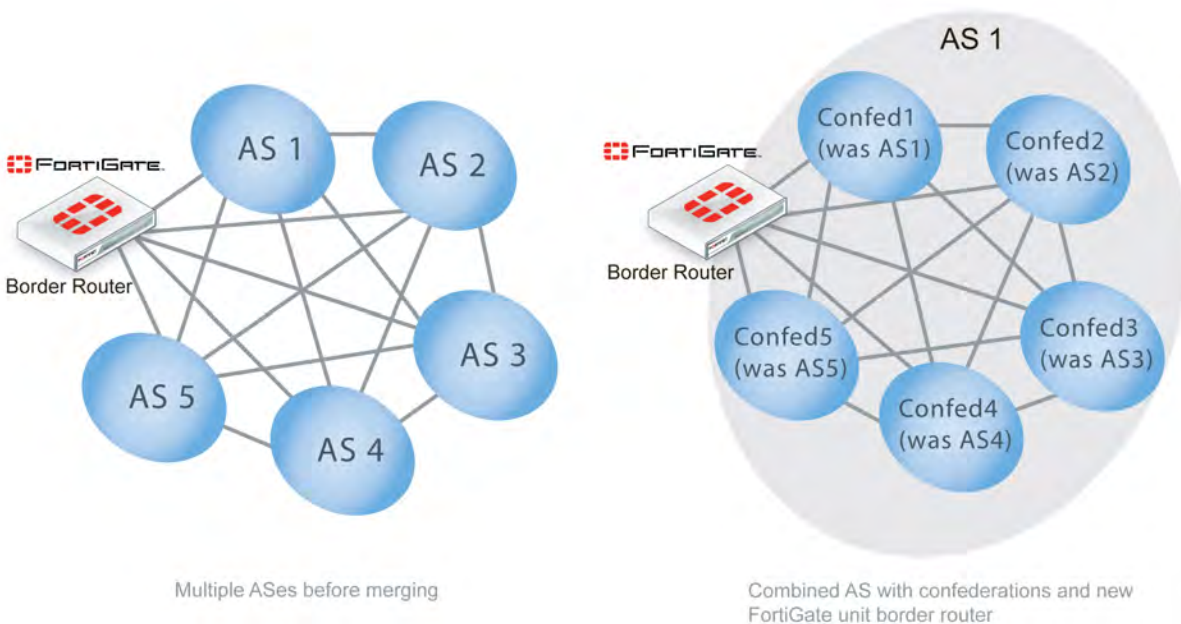

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in [RFC 3065](#) and [RFC 1965](#).

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications because many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, which requires few changes. Any additional permanent changes can then be implemented over time, as required. The diagram below shows the group of ASs before merging and the corresponding confederations afterward, as part of the single AS with the addition of a new border router. It should be noted that after merging, if the border router becomes a route reflector, then each confederation only needs to communicate with one other router instead of five others.

## AS merging using confederations

Confederations and RRs perform similar functions: they both sub-divide large ASs for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, whereas routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS\_PATH attribute, making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
 set confederation-identifier <peerid_integer>
end
```

## BGP conditional advertisements

Normally, routes are propagated regardless of the existence of a different path. The BGP conditional advertisement feature allows a route not to be advertised, based on the existence or non-existence of other routes. With this feature, a child table under `bgp.neighbor` is introduced. Any route matched by one of the route-maps specified in the table will be advertised to the peer, based on the corresponding route-map condition.

You can enable and disable conditional advertisements using the CLI.

### To configure BGP conditional advertisements - CLI:

```
config router bgp
 set as 3
 config neighbor
 edit "10.10.10.10"
 set remote-as 3
 config conditional-advertise
 edit "route-map-to-match-sending"
```

```

 set condition-routemap "route-map-to-match-condition"
 set condition-type [exist | non-exist]
 next
end
next
end

```

## BGP neighbor groups

The BGP neighbor group feature allows a large number of neighbors to be configured automatically based on a range of neighbors' source addresses.

### To configure BGP neighbor groups - CLI:

Start by adding a BGP neighbor group:

```

config router bgp
 config neighbor-group
 edit <neighbor-group-name>
 set remote-as 100
 ...

```

(All options for BGP neighbor group are supported except `password`.)

```

end

```

Then add a BGP neighbor range:

```

config router bgp
 config neighbor-range
 edit 1
 set prefix 192.168.1.0/24
 set max-neighbor-num 100
 set neighbor-group <neighbor-group-name>
 next
 end

```

## Network Layer Reachability Information

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that, when combined, are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

## BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route and are modified, as required, along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

| Attribute                    | Description                                                                                                                                                               |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AS_PATH</b>               | A list of ASs a route has passed through. For more information, see <a href="#">AS_PATH on page 2605</a> .                                                                |
| <b>MULTI_EXIT_DESC (MED)</b> | Which router to use to exit an AS with more than one external connection. For more information, see <a href="#">MULTI_EXIT_DESC on page 2606</a> .                        |
| <b>COMMUNITY</b>             | Used to apply attributes to a group of routes. For more information, see <a href="#">COMMUNITY on page 2606</a> .                                                         |
| <b>NEXT_HOP</b>              | Where the IP packets should be forwarded to, like a gateway in static routing. For more information, see <a href="#">NEXT_HOP on page 2607</a> .                          |
| <b>ATOMIC_AGGREGATE</b>      | Used when routes have been summarized to tell downstream routers not to de-aggregate the route. For more information, see <a href="#">ATOMIC_AGGREGATE on page 2607</a> . |
| <b>ORIGIN</b>                | Used to determine if the route is from the local AS or not. For more information, see <a href="#">ORIGIN on page 2607</a> .                                               |
| <b>LOCAL_PREF</b>            | Used only within an AS to select the best route to a location (like MED).                                                                                                 |

Inbound policies on FortiGate units can change the NEXT-HOP, LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

## AS\_PATH

AS\_PATH is the BGP attribute that keeps track of each AS that a route advertisement has passed through. AS\_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS\_PATH with that router's AS in it. The diagram below shows the route between Router A and Router B. The AS\_PATH from A to B would read 701,702,703 for each AS that the route passes through.

As of the beginning of 2010, the industry upgraded from 2-byte to 4-byte AS\_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS\_PATH numbers. FortiOS supports 4-byte AS\_PATHs in its BGP implementation.

## AS\_PATH of 701,702, 703 between routers A and B

The BGP commands related to AS\_PATH include:

```
config router bgp
 set bestpath-as-path-ignore {enable | disable}
end
```

## MULTI\_EXIT\_DESC

BGP AS systems can have one or more routers that connect them to other ASs. For ASs with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes, such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the MED attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information, which can be suspicious as a possible hacking attempt or an attack on the network. At best, it signifies an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
 set always-compare-med {enable | disable}
 set bestpath-med-confed {enable | disable}
 set bestpath-med-missing-as-worst {enable | disable}
 set deterministic-med {enable | disable}
 config neighbor
 set attribute-unchanged [as-path] [med] [next-hop]
 end
end
```

## COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see [RFC 1997](#)). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
 set send-community {both | disable | extended | standard}
end
```

## NEXT\_HOP

The NEXT\_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT\_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT\_HOP information that is sent to IBGP peers. This is changed with the `config neighbor, set next-hop-self` command.

The BGP commands related to NEXT\_HOP include:

```
config router bgp
 config neighbor
 set attribute-unchanged [as-path] [med] [next-hop]
 set next-hop-self {enable | disable}
 end
end
```

## ATOMIC\_AGGREGATE

The ATOMIC\_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates for. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit does not specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC\_AGGREGATE include:

```
config router route-map
 edit <route_map_name>
 config rule
 edit <route_map_rule_id>
 set set-aggregator-as <id_integer>
 set set-aggregator-ip <address_ipv4>
 set set-atomic-aggregate {enable | disable}
 end
 end
 end
```

## ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are, by default, higher priority than external routes (EBGP). However, incomplete ORIGINS are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
 edit <route_map_name>
 set comments <string>
 config rule
 edit <route_map_rule_id>
 set match-origin {egp | igp | incomplete | none}
 end
 end
 end
end
```

## How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other and establish a connection, they go from the idle state and through the various states until they reach the established state. An error can cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used, such as multiprotocol extensions, that can include IPv6 and VPNs.

## IBGP versus EBGp

When you read about BGP, you often see EBGp or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASs) and interior BGP (IBGP) involves packets that stay within a single AS. For example, the AS\_PATH attribute is only useful for EBGp where routes pass through multiple ASs.

These two modes are important because some features of BGP are used only for one of EBGp or IBGP. For example, confederations are used in EBGp and RRs are used only in IBGP. Also, routes learned from IBGP have priority over routes learned from EBGp.

FortiGate units have some commands that are specific to EBGp, including:

- automatically resetting the session information to external peers if the connection goes down: `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (you must also configure local and internal distances if this is set): `set distance-external <distance_integer>`
- enforcing EBGp multihops and their TTL (number of hops): `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

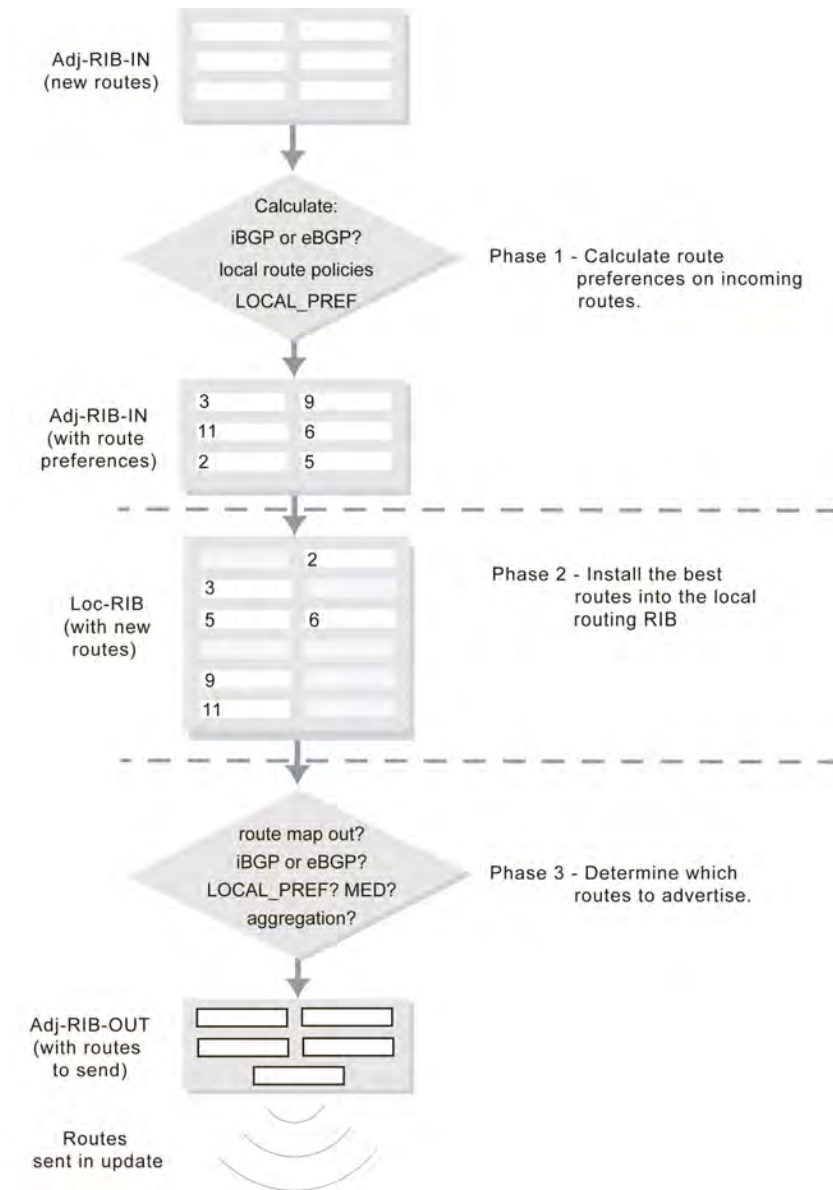

## BGP path determination: which route to use

Firstly, recall that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute, to allow an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates or when the FortiGate unit sends out BGP updates.

### The three phases of a BGP routing decision

### Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL\_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

## Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT\_HOP checked to ensure the destination is reachable. If it is reachable, the AS\_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If there are multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following, in descending order of importance: shortest AS\_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT\_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed, the Loc-RIB will consist of the best of both the new and older routes.

## Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also, any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

## Aggregate routes and addresses

BGP-4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing allows the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see [Dynamic routing overview on page 2503](#).

The ATOMIC\_AGGREGATE attribute informs routers that the route has been aggregated and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
 config aggregate-address
 edit <aggr_addr_id>
 set as-set {enable | disable}
 set prefix <address_ipv4mask>
 set summary-only {enable | disable}
 end
 config aggregate-address6
 edit <aggr_addr_id>
 set as-set {enable | disable}
 set prefix6 <address_ipv6mask>
 set summary-only {enable | disable}
 end
```

## Configuring BGP graceful restart process on timer

You can configure the BGP graceful restart process to stop only when the restart timer expires, using the following CLI commands:

```
config router bgp
```

```
set graceful-end-on-timer enable
```

### Configuring option to bring down BGP neighbor when the link is down

You can configure an option to bring down BGP neighbors when the outgoing interface is down, using the following CLI commands:

```
config router bgp
 config neighbor
 edit <ip_address>
 set linkdown-failover enable
```

### Configuring option to keep routes for a period after the BGP neighbor is down

You can configure an option to keep routes for a period after the BGP neighbor is down. If you enable this option for a BGP neighbor, the route learned from the neighbor is kept for the configured `graceful-stalepath-time` after the neighbor is down because of hold timer expiration or TCP connection failure.

To configure this option, use the following CLI commands:

```
config router bgp
 config neighbor
 edit <ip_address>
 set stale-route enable
```

### BGP local-AS support

FortiGate supports BGP local-AS. Local-AS allows you to configure a BGP speaker to have a real local-AS and a secondary local-AS for a specific neighbor, so its local-AS number appears different to different neighbors.

You can configure a BGP speaker to have a real local-AS and a secondary local-AS for a specific neighbor, so the local-AS number appears different to neighbor B and neighbor A.

### Configuring BGP local-AS

To configure BGP local-AS for BGP peers, use the following CLI commands:

```
config router bgp
 config neighbor
 edit "neighbor" / edit <ip_address>
 ...
 set local-as 300 (?) / set local-as <integer>
 set local-as-no-prepend {enable | disable}
 set local-as-replace-as {enable | disable}
 end
```

| CLI option                              | Description                                                                    |
|-----------------------------------------|--------------------------------------------------------------------------------|
| <ip_address>                            | The IP/IPv6 address of neighbor                                                |
| <local-as <integer>>                    | The local-AS number                                                            |
| local-as-no-prepend { enable   disable} | Set this to enable if you do not want to prepend local-AS to incoming updates. |

| CLI option                               | Description                                                                |
|------------------------------------------|----------------------------------------------------------------------------|
| local-as-replace-as { enable   disable } | Set this to enable to replace a real AS with local-AS in outgoing updates. |

## Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

### Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

### Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty network cable that wobbles online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this does not occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also, configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with route flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- [Holdtime timer](#)
- [Dampening](#)

- Graceful restart
- Bi-directional forwarding detection

### Holdtime timer

The first line of defense to a flapping route is the holdtime timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holdtime timer will not allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit. For the duration of the other outages, there will be no changes because the Fortigate unit is essentially treating this router as down. If the route is still flapping after the timer expires, it will happen all over again.

Even if the route is not flapping (for example, if it goes down, comes up, and stays back up) the timer still counts down and the route is ignored for the duration of the timer. In this situation, the route will be seen as down longer than it really is but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also, the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically, you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holdtime timer.

### How to configure the holdtime timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holdtime timer.

For example, your network has two routes that you want to set the holdtime timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it cannot be down for long if it is down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holdtime timer for the main route should be fairly short (for example, 60 seconds) instead of the default. The second route timer can be left at the default, since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
 config neighbor
 edit 10.12.101.4
 set holdtime-timer 60
 next
 edit 10.13.101.4
 set holdtime-timer 180
 next
 end
end
```

### Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap does not start dampening, but the second flap starts a timer where the router will not use that route because it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the

dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
or
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
 set dampening {enable | disable}
 set dampening-max-suppress-time <minutes_integer>
 set dampening-reachability-half-life <minutes_integer>
 set dampening-reuse <reuse_integer>
 set dampening-route-map <routemap-name_str>
 set dampening-suppress <limit_integer>
 set dampening-unreachability-half-life <minutes_integer>
end
```

## Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise that it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there is a flap, the HA cluster routing table will be out-of-date.

For example, your FortiGate unit is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbours stating how long it expects to be offline. This way, its neighboring routers do not remove it from their routing tables. However, if that router is not back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

## Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software and neighboring BGP routers.

For example, if a neighbor of your FortiGate unit with an IP address of 172.20.120.120 supports graceful restart, enter the command:

```
config router bgp
 config neighbor
 edit 172.20.120.120
 set capability-graceful-restart enable
 end
 end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit to be offline, enter the command:

```
config router bgp
 set graceful-restart enable
 set graceful-restart-time 120
 set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are:

```
config router bgp
 set graceful-restart { disable| enable}
 set graceful-restart-time <seconds_integer>
 set graceful-stalepath-time <seconds_integer>
 set graceful-update-delay <seconds_integer>
 config neighbor
 set capability-graceful-restart {enable | disable}
 end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it is restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it is done restarting.

### Bi-directional forwarding detection

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection, that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

### Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for

the FortiGate unit, it could be disabled only for a single interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the [FortiGate CLI Reference](#).

BFD can be configured only through the CLI.

The BGP commands related to BFD are:

```
config system {setting | interface}
 set bfd {enable | disable | global}
 set bfd-desired-mix-tx <milliseconds>
 set bfd-detect-mult <multiplier>
 set bfd-required-mix-rx <milliseconds>
 set bfd-dont-enforce-src-port {enable | disable}

config router bgp
 config neighbor
 edit <neighbor_address_ipv4>
 set bfd {enable | disable}
 end
 end

get router info bfd neighbor
execute router clear bfd session <src_ipv4> <dst_ipv4> <interface>
```

The `config system` commands allow you to configure whether BFD is enabled in a particular unit/vdom or individual interface, and how often the interface requires the sending and receiving of BFD information.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to make use of it.

## Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent updates that are not needed and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about: the 2 ISP border routers and the FortiGate unit. This means that the FortiGate unit will have only two neighbor routers to configure.

This configuration has the added benefit of being easy to expand if the company wants to add a remote office in the future.

To keep the configuration simple, the company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web mail.

### Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- Redundant Internet connection that essentially never fails
- Faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- Load balancing traffic to the company network
- Easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- Easier to create protection policies for different traffic through a specific ISP

Some companies require reliable Internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences can easily be life or death.

Dual homing is an extra expense for the second ISP connection and more work to configure and maintain the more complex network topology.

### Potential dual homing issues

BGP comes with load balancing issues and dual homing is in the same category. BGP does not inherently deal well with load balancing or getting default routes through BGP. Ideally, one connection may be best for certain destinations but it may not have that traffic routed to it, which makes the load balancing less than perfect. This kind of fine tuning can be very time consuming and usually results in a best effort situation.

When dual homing is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problem with this situation is that your traffic may not have the bandwidth it needs, and you will also be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs, in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening, you can turn on asymmetric routing on the FortiGate unit (`config system settings, set asymmetric enable`) to verify if that is the problem. Turn this feature off once this is established, since it disables many features on the FortiGate by disabling stateful inspection. Solutions to this problem can include using static routes for default routes instead of learning them through BGP or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

### Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration, the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network: the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, which is an address supplied by the ISP.
- The FortiGate unit external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, which is an address supplied by the ISP.
- ISP1 AS has an AS number of 650001 and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.

- Apart from graceful restart and shorter timers (holdtimer and keepalive), default settings are to be used whenever possible.

### Basic BGP network topology

### Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route and ISP2 is the secondary route
- All basic configuration can be completed in both the GUI and CLI
- Only one AS is used for the company

For these reasons, this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- Changing redistribution defaults (make link when example is set up)
- IPv6

For more information about these features, see the corresponding section.

## Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the company network and the ISP network. The FortiGate unit is the only BGP router on the company network, but there is at least one other BGP router on the ISP network. There may be more BGP routers, but we do not have that information.

As mentioned in the general configuration steps, the ISP must be notified of the company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled, such as graceful restart or route dampening, that should be determined ahead of time so those features can be enabled on the FortiGate unit.

### To configure the FortiGate unit as a BGP router

1. [Configure interfaces and default routes](#)
2. [Configure firewall services, addresses, and policies](#)
3. [Set the FortiGate BGP information](#)
4. [Add the internal network to the AS](#)
5. [Additional FortiGate BGP configuration](#)

### Configure interfaces and default routes

The FortiGate unit is connected to three networks: the company network on the internal interface, the ISP1 network on the external1 interface, and the ISP2 network on the external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required, such as setting the maximum MTU size or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled as Internal or External. Instead, for clarity, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here also. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

### To configure the FortiGate interfaces - web-based manager

1. Go to **Network > Interfaces**.
2. Edit port 1 (internal) interface.
3. Set the following information and select **OK**.

|                              |                             |
|------------------------------|-----------------------------|
| <b>Alias</b>                 | internal                    |
| <b>IP/Network Mask</b>       | 10.11.101.110/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING              |

|                        |                          |
|------------------------|--------------------------|
| <b>Comments</b>        | Company internal network |
| <b>Interface State</b> | Enabled                  |

4. Edit port 2 (external1) interface.
5. Set the following information and select **OK**.

|                              |                            |
|------------------------------|----------------------------|
| <b>Alias</b>                 | external1                  |
| <b>IP/Network Mask</b>       | 172.21.111.5/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING             |
| <b>Comments</b>              | ISP1 External BGP network  |
| <b>Interface State</b>       | Enabled                    |

6. Edit port 3 (external2) interface.
7. Set the following information and select **OK**.

|                              |                            |
|------------------------------|----------------------------|
| <b>Alias</b>                 | external2                  |
| <b>IP/Network Mask</b>       | 172.22.222.5/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING             |
| <b>Comments</b>              | ISP2 External BGP network  |
| <b>Interface State</b>       | Enabled                    |

### To configure the FortiGate interfaces - CLI

```
config system interface
 edit port1
 set alias internal
 set ip 10.11.101.110 255.255.255.0
 set allowaccess http https ssh
 set description "Company internal network"
 set status up
 next
 edit port2
 set alias external1
 set ip 172.21.111.5 255.255.255.0
 set allowaccess https ssh
 set description "ISP1 External BGP network"
 set status up
 next
 edit port3
 set alias external2
 set ip 172.22.222.5 255.255.255.0
 set allowaccess https ssh
 set description "ISP2 External BGP network"
```

```

 set status up
 next
end

```

### To configure default routes for both ISPs - web-based manager

1. Go to **Network > Static Routes**.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select **Create New** and set the following information.

|                                |                 |
|--------------------------------|-----------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0 |
| <b>Gateway</b>                 | 172.21.111.5    |
| <b>Interface</b>               | port2           |
| <b>Administrative Distance</b> | 10              |

4. Select **OK**.
5. Select **Create New** and set the following information.

|                                |                 |
|--------------------------------|-----------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0 |
| <b>Gateway</b>                 | 172.22.222.5    |
| <b>Interface</b>               | port3           |
| <b>Administrative Distance</b> | 15              |

6. Select **OK**.

### To configure default routes for both ISPs - CLI

```

config router static
 edit 1
 set device "port2"
 set distance 10
 set gateway 172.21.111.5
 next
 edit 2
 set device "port3"
 set distance 15
 set gateway 172.22.222.5
 next
end

```

### Configure firewall services, addresses, and policies

To create the security policies, you create the firewall services group that will include all the services that will be allowed, define the addresses that will be used in the security policies, and configure the security policies themselves.

To keep the configuration simple, the company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also, BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example, if only 20 addresses are used, only allow those addresses in the range.

To keep things simple, a zone will be used to group the two ISP interfaces together. This will allow for the use of one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple and if there is a need for separate policies for each ISP in the future, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports and the internal network.

More policies or services can be added in the future as applications are added to the network.

When configuring security policies, always enable logging to help you track and debug your traffic flow.

### To create a firewall services group - web-based manager

1. Go to **Policy & Objects > Services**, select the dropdown arrow next to **Create New** and select **Service Group**.
2. For **Group Name**, enter "Basic\_Services".
3. From the **Members** dropdown, choose the following six services: BGP, FTP, FTP\_GET, FTP\_PUT, DNS, HTTP, and HTTPS.
4. Select **OK**.

### To create a firewall services group - CLI

```
config firewall service group
 edit "Basic_Services"
 set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
 next
end
```

### To create a zone for the ISP interfaces - web-based manager

1. Go to **Network > Interfaces**.
2. Select the caret to the right of **Create New** and then select **Zone**.
3. Enter the following information:

| Name | ISPs |
|------|------|
|------|------|

|                                 |             |
|---------------------------------|-------------|
| <b>Block intra-zone traffic</b> | enable      |
| <b>Interface Members</b>        | port2 port3 |

4. Select **OK**.

#### To create a zone for the ISP interfaces - CLI

```
config system zone
 edit "ISPs"
 set interface "port2" "port3"
 set intrazone block
 next
end
```

#### To add the firewall addresses - web-based manager

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and set the following information.

| Category                 | Address                   |
|--------------------------|---------------------------|
| <b>Name</b>              | Internal_network          |
| <b>Type</b>              | Subnet / IP Range         |
| <b>Subnet / IP Range</b> | 10.11.101.0 255.255.255.0 |
| <b>Interface</b>         | port1                     |

3. Select **OK**.

#### To add the firewall addresses - CLI

```
config firewall address
 edit "Internal_network"
 set associated-interface "port1"
 set subnet 10.11.101.0 255.255.255.0
 next
end
```

#### To add the HTTP and DNS security policies - web-based manager

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Set the following information.

|                           |                 |
|---------------------------|-----------------|
| <b>Incoming Interface</b> | port1(internal) |
| <b>Outgoing Interface</b> | ISPs            |

|                                   |                                |
|-----------------------------------|--------------------------------|
| <b>Source</b>                     | Internal_network               |
| <b>Destination</b>                | All                            |
| <b>Schedule</b>                   | Always                         |
| <b>Service</b>                    | Basic_services                 |
| <b>Action</b>                     | ACCEPT                         |
| <b>Firewall / Network Options</b> | Enable NAT                     |
| <b>Log Allowed Traffic</b>        | Enable                         |
| <b>Comments</b>                   | ISP1 basic services out policy |

3. Select **OK**.

4. Select **Create New** and set the following information.

|                                   |                               |
|-----------------------------------|-------------------------------|
| <b>Incoming Interface</b>         | ISPs                          |
| <b>Outgoing Interface</b>         | port1(internal)               |
| <b>Source</b>                     | All                           |
| <b>Destination</b>                | Internal_network              |
| <b>Schedule</b>                   | Always                        |
| <b>Service</b>                    | Basic_services                |
| <b>Action</b>                     | ACCEPT                        |
| <b>Firewall / Network Options</b> | Enable NAT                    |
| <b>Log Allowed Traffic</b>        | Enable                        |
| <b>Comments</b>                   | ISP1 basic services in policy |

### To add the security policies - CLI

```
config firewall policy
edit 1
set srcintf "port1"
set srcaddr "Internal_network"
set dstintf "ISPs"
set dstaddr "all"
set schedule "always"
set service "Basic_services"
set action accept
set nat enable
set profile-status enable
```

```
 set logtraffic enable
 set comments "ISP1 basic services out policy"
 next
 edit 2
 set srcintf "ISPs"
 set srcaddr "all"
 set dstintf "port1"
 set dstaddr "Internal_network"
 set schedule "always"
 set service "Basic_services"
 set action accept
 set nat enable
 set profile-status enable
 set logtraffic enable
 set comments "ISP1 basic services in policy"
 next
end
```

### Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration, the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbor, even that route out is not available. So, while after this part of the configuration is complete, your FortiGate unit will be running BGP, it will not know about any other routers running BGP until the next part of the configuration is complete.

#### To set the BGP router information - web-based manager

1. Go to **Network > BGP**.
2. Set the following information and select **OK**.

|                  |               |
|------------------|---------------|
| <b>Local AS</b>  | 1             |
| <b>Router ID</b> | 10.11.101.110 |

#### To set the BGP router information - CLI

```
config router BGP
 set as 1
 set router-id 10.11.101.110
end
```

### Add the internal network to the AS

The company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASs. The internal network in the Company's AS must be defined. If there were other networks in the company, such as regional offices, they would be added here as well.

#### To set the networks in the AS - web-based manager

1. Go to **Network > BGP**.
2. Under **Networks**, set the **IP/Netmask** to `10.11.101.0/255.255.255.0` and select **Add**.

### To set the networks in the AS - CLI

```
config router bgp
config network
edit 1
set prefix 10.11.101.0 255.255.255.0
next
end
end
```

### Add BGP neighbor information

The configuration will not work unless you set **Remote AS** neighbors. This can be done in either the web-based manager or the CLI.

### To configure the BGP neighbors - web-based manager

1. Go to **Network > BGP**.
2. Add a **Neighbors IP** of 172.21.111.4 with the **Remote AS** set to 650001, then click **Add/Edit**.
3. Add another **Neighbors IP** of 172.22.222.4 with the **Remote AS** set to 650002, then click **Add/Edit**.

### To configure the BGP neighbors - CLI

```
config router BGP
set as 1
config neighbor
edit "172.21.111.4"
set remote-as 650001
next
edit "172.22.222.4"
set remote-as 650002
next
end
end
```

### Additional FortiGate BGP configuration

At this point, those are all the settings that can be done in both the web-based manager and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers, such as keepalive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simple features are being used to promote faster detections of network failures, which will result in better service for the company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit and, where possible, on neighboring routers as well:

- **bestpath-med-missing-as-worst**: treats a route without an MED as the worst possible available route due to expected unreliability
- **fast-external-failover**: immediately reset the session information associated with BGP external peers if the link used to reach them goes down

- `graceful-restart*`: advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands apply to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer`: how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer`: how often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes`: log changes to the status of neighbor routers. This can be useful for troubleshooting from both internal and external networks.
- `connect-timer`: how long (in seconds) the FortiGate unit will try to reach this neighbor before declaring it offline.
- `weight`: used to prefer routes from one neighbor over the other. In this example, ISP1 is the primary connection so it is weighted higher than ISP2

### To configure additional BGP options - CLI

```
config router bgp
 set bestpath-med-missing-as-worst enable
 set fast-external-failover enable
 set graceful-restart enable
 set graceful-restart-time 120
 set graceful-stalepath-time 180
 set graceful-update-delay 180
 set holdtime-timer 120
 set keepalive-timer 45
 set log-neighbor-changes enable
 config neighbor
 edit 172.21.111.4
 set connect-timer 60
 set description "ISP1"
 set holdtime-timer 120
 set keepalive-timer 45
 set weight 250
 next
 edit 172.22.222.4
 set connect-timer 60
 set description "ISP2"
 set holdtime-timer 120
 set keepalive-timer 45
 set weight 100
 next
 end
end
```

### Configuring other networking devices

There are two other networking devices that need to be configured: the BGP routers for both ISPs.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2, that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- The router ID
- Your company's AS number

## Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm that things are working as expected.

In general, for routing, you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real-time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in the following parts:

- [Testing network connectivity](#)
- [Verifying the FortiGate unit's routing tables](#)
- [Verifying traffic routing](#)
- [Verifying the dual-homed side of the configuration](#)

## Testing network connectivity

A common first step in testing a new network topology is to test to see if you can reach the Internet and other locations as expected. If not, you may be prevented by cabling issues, software, or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit's interfaces and ISP routers have ping support enabled. Also, ensure that the security policies allow ping through the firewall.

Connections to test, in this example, are the internal network to ISP1's router or the Internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. These three tests should prove your basic network connections are working.

Once you have finished testing the network connectivity, turn off ping support on the external interfaces for additional security.

---

## Verifying the FortiGate unit's routing tables

The FortiGate routing table contains the routes that are stored for future use. If you are expecting certain routes to be there and they are not, this is a good indicator that your configuration is not what you expected.

The `get router info routing-table details` CLI command will provide you with the routing protocol, destination address, gateway address, interface, and weighting for every route, as well as if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the `get router info routing-table bgp` CLI command. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command, you can replace BGP with static, or other routing protocols, to only display those routes.

If you want to see the contents of the routing information database (RIB), use the `get router info routing-table database` CLI command. This will display the incoming routes that may or may not make it into the routing table.

### Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try to access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

### Verifying the dual-homed side of the configuration

Since there are two connections to the Internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer the other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- Default static routes: If these are wrong or do not exist, the traffic cannot get out.
- BGP neighbor information: If the ISP router information is incorrect, the FortiGate unit will not be able to talk to it.

## Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best not to advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way or for some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example, the company has an internal network in an OSPF area and is connected to a BGP AS and two BGP peers. The company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

### Network layout and assumptions

The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers, as shown below. In this configuration, the FortiGate unit is the BGP border router between the Company AS and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example shared by the FortiGate unit and both peers: AS 65001.
- The company's FortiGate unit connects to the Internet through two BGP peers.
- The company's internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate unit's interfaces are connected as follows:

- port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
- port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
- port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

### BGP network topology

### Assumptions

The BGP redistributing routes configuration procedure follows these assumptions:

- The FortiGate unit has been configured following the Install Guide
- Interfaces port1, port2, and port3 exist on the FortiGate unit
- We do not know the router manufacturers of Peer 1 and Peer 2
- We do not know what other devices are on the BGP AS or OSPF Area
- All basic configuration can be completed in both GUI and CLI
- Access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

### Configuring the FortiGate unit

1. [Configuring networks and firewalls on the FortiGate unit](#)
2. [Configuring BGP on the FortiGate unit](#)
3. [Configuring OSPF on the FortiGate unit](#)

4. [Configuring other networking devices](#)
5. [Configuring ECMP support for BGP](#)

### Configuring networks and firewalls on the FortiGate unit

The FortiGate unit has three interfaces connected to networks: two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network: either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web server services (DNS, HTTP, HTTPS, SSH, NTP, FTP\*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). To increase security, PING and TRACEROUTE can be removed once the network is up and working properly. Other services can be added later, as needed.

#### To configure the interfaces - web-based manager

1. Go to **Network > Interfaces**.
2. Edit port1 (dmz) interface.
3. Set the following information and select **OK**.

|                              |                             |
|------------------------------|-----------------------------|
| <b>Alias</b>                 | dmz                         |
| <b>IP/Network Mask</b>       | 10.11.201.110/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH PING              |
| <b>Description</b>           | OSPF internal networks      |
| <b>Administrative Status</b> | Up                          |

4. Edit port2 (external1) interface.
5. Set the following information and select **OK**.

|                              |                            |
|------------------------------|----------------------------|
| <b>Alias</b>                 | external1                  |
| <b>IP/Network Mask</b>       | 172.21.111.4/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH                  |
| <b>Description</b>           | BGP external Peer 1        |
| <b>Administrative Status</b> | Up                         |

6. Edit port3 (external2) interface.
7. Set the following information and select **OK**.

|              |           |
|--------------|-----------|
| <b>Alias</b> | external2 |
|--------------|-----------|

|                              |                            |
|------------------------------|----------------------------|
| <b>IP/Network Mask</b>       | 172.22.222.4/255.255.255.0 |
| <b>Administrative Access</b> | HTTPS SSH                  |
| <b>Description</b>           | BGP external2 Peer2        |
| <b>Administrative Status</b> | Up                         |

### To configure the FortiGate interfaces - CLI

```

config system interface
 edit port1
 set alias dmz
 set ip 10.11.201.110 255.255.255.0
 set allowaccess https ssh ping
 set description "OSPF internal networks"
 set status up
 next
 edit port2
 set alias external1
 set ip 172.21.111.5 255.255.255.0
 set allowaccess https ssh
 set description "external1 Peer 1"
 set status up
 next
 edit port3
 set alias external2
 set ip 172.22.222.5 255.255.255.0
 set allowaccess https ssh
 set description "external2 Peer 2"
 set status up
 next
end

```

### To configure the firewall addresses - web-based manager

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New** and set the following information.

|                          |                           |
|--------------------------|---------------------------|
| <b>Category</b>          | Address                   |
| <b>Name</b>              | BGP_services              |
| <b>Type</b>              | Subnet / IP Range         |
| <b>Subnet / IP Range</b> | 10.11.201.0 255.255.255.0 |
| <b>Interface</b>         | port1                     |

3. Select **OK**.

### To configure the firewall addresses - CLI

```
config firewall address
 edit "BGP_services"
 set associated-interface "port1"
 set subnet 10.11.201.0 255.255.255.0
 next
end
```

### To configure firewall service groups - web-based manager

1. Go to **Policy & Objects > Objects > Services**. Under the **Create New** dropdown menu, select **Service Group**.
2. Name the group BGP\_Services.
3. Add the following services to the **Members** list: BGP, DNS, FTP, FTP\_GET, FTP\_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
4. Select **OK**.
5. Create another new **Service Group**.
6. Name the group OSPF\_Services.
7. Add the following services to the *Members* list: DNS, FTP, FTP\_GET, FTP\_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
8. Select **OK**.

### To configure firewall service groups - CLI

```
config firewall service group
 edit "BGP_services"
 set member "BGP", "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP"
 "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG"
 next
 edit "OSPF_services"
 set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP" "MYSQL"
 "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG" "OSPF"
 next
end
```

## Configuring BGP on the FortiGate unit

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1's routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it does not make sense to advertise unneeded routes.

Blocking Peer 1's routes to Peer 2 is done with the distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case, we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

### To create access list to block Peer 1 - CLI

```
config access-list
 edit "block_peer1"
```

```

config rule
edit 1
 set prefix 172.21.111.0 255.255.255.0
 set action deny
 set exact-match enable
end
end
end

```

### To configure BGP on the FortiGate unit - CLI

```

config router bgp
set as 65001
set router-id 10.11.201.110
config redistribute ospf
set status enable
end
config neighbor
edit 172.22.222.5
set remote-as 65001
set distribute-list-out "block_peer1"
next
edit 172.21.111.5
set remote-as 65001
end
end

```

### Configuring OSPF on the FortiGate unit

This configuration involves only one OSPF area, so all traffic will be intra-area. If there were two or more areas with traffic going between them, it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBGP). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic, apart from redistributing BGP routes learned.

### To configure OSPF on the FortiGate unit - web-based manager

1. Go to **Router > Dynamic > OSPF**.
2. For Router ID enter `10.11.201.110` and then select **Apply**.
3. Under **Advanced Options > Redistribute**, select **BGP** and set the BGP **Metric** to 1.
4. For **Areas**, select **Create New**, enter the following information and then select **OK**.

|                       |         |
|-----------------------|---------|
| <b>Area (IP)</b>      | 0.0.0.0 |
| <b>Type</b>           | Regular |
| <b>Authentication</b> | None    |

5. For **Networks**, select **Create New**.
6. Enter `10.11.201.0/255.255.255.0` for **IP/Netmask**, and select **OK**.
7. For **Interfaces**, select **Create New**.

8. Enter `OSPF_dmz_network` for **Name**.
9. Select `port1(dmz)` for **Interface** and then select **OK**.

### To configure OSPF on the FortiGate unit - CLI

```
config router ospf
 set router-id 10.11.201.110
 config area
 edit 0.0.0.0
 set type regular
 set authentication none
 end
 config network
 edit 1
 set area 0.0.0.0
 set prefix 10.11.201.0 255.255.255.0
 end
 config interface
 edit "OSPF_dmz_network"
 set interface port1(dmz)
 set status enable
 end
 config redistribute bgp
 set status enable
 set metric 1
 end
end
```

### Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information, including IP address, AS number, and what capabilities are being used, such as IPv6, graceful restart, BFD, and so on.

### Configuring ECMP support for BGP

Equal Cost Multiple Path (ECMP) is a mechanism that allows multiple routes to the same destination with different next-hops and load-balances routed traffic over those multiple next-hops.

- ECMP only works for routes that are sourced by the same routing protocol (Static Routes, OSPF, and BGP).
- ECMP is enabled, by default, with 10 paths.
- ECMP with static routes is effective if the routes are configured with the same distance and same priority.

### To configure ECMP support - CLI

```
config router bgp
 set ebgp-multipath disable[|enable]
 set ibgp-multipath disable[|enable]
 ...
end
```

### Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensures that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also, check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure that no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see [Redistributing and blocking routes in BGP on page 2629](#).

## IS-IS

This section describes the Intermediate System to Intermediate System Protocol (IS-IS).

### IS-IS background and concepts

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) that is not intended to be used between Autonomous Systems (AS).

#### Background

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see [RFC 1142](#), note that this RFC is different from the ISO version). About the same time, the Internet Engineering Task Force developed OSPF (see [OSPF on page 2557](#)). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see [RFC 1195](#)). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol that is well-suited to smaller networks. It is in widespread use and has near universal support on routing hardware. It is quick to configure and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, cannot choose routes based on different quality of service methods, and can create network loops if you are not careful. IS-IS uses Dijkstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

The FortiGate implementation supports IS-IS for IPv4 (see [RFCs 1142](#) and [1162](#)), but does not support IS-IS for IPv6 (although this technically can be achieved using the ZebOS routing module).

### How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm is not complex, there are some options to allow fine-tuning, and it is straightforward to configure IS-IS on FortiGate units.

From [RFC 1142](#):

*The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm. Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.*

#### IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence: static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so it is neither a strength or a weakness.

## TLV

IS-IS uses *type-length-variable (TLV)* parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and “L” octets of value (V). They are included in all of the IS-IS [Packet types](#). For a complete breakdown of the LSP, see [LSP structure on page 2638](#).

In IS-IS, TLVs are used to determine route-leaking and authentication and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, see [Default routing on page 2640](#).
- To determine which TLVs are responsible for authentication, see [Authentication on page 2642](#).

For a complete list of reserved TLV codepoints, refer to [RFC 3359](#).

## LSP structure

It is difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriately.

This section provides information about the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

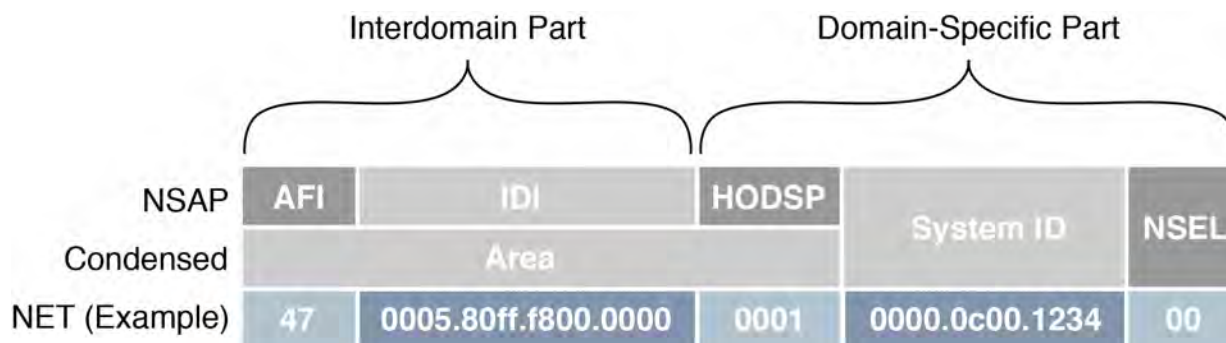

## NSAP and NET

IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAP). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the *n-selector* (NSEL). In order for adjacencies to form in IS-IS, the NSEL must be set to zero, to indicate “this system”. The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below:

### NSAP and NET example

- **AFI** : The *Authority and Format Identifier (AFI)* specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.
- **IDI**: The *Initial Domain Identifier (IDI)* identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you do not need to specify an IDI since the network is private.
- **HODSP** : The *High Order Domain-Specific Part (HODSP)* identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.
- **System ID** : The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.
- **NSEL**: The *n-selector (NSEL)*, as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

## Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

### DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose, the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSD) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

### Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

- **Intermediate System-to-Intermediate System Hello (IIH) PDU** : As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS. Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies. The DIS typically floods Hello packets to the entire LAN every three seconds.
- **Link-state PDU (LSP)** : The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated. For a more detailed breakdown of the LSP, see [LSP structure on page 2638](#).
- **Complete sequence number PDU (CSNP)**: CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge. In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbors. In other words, they are never flooded.
- **Partial sequence number PDU (PSNP)** : PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

## Default routing

The default route is used if there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to **Monitor > Routing Monitor**.

## Route leaking

Route leaking is the term used to describe the bi-directional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to leak Level 2 routing information into a Level 1 area, you must configure an export policy. Whether or not a route is leaked is determined by the ATT bit, using TLV 128 (for internal IP reachability) and TLV 130 (for external IP address information). For more information about TLVs, see [Troubleshooting IS-IS on page 2643](#).

To configure IS-IS route leaking, use the following CLI commands.

1. On a Level 1-2 router:

```
config router isis
 set redistribute-l2 enable
end
```

2. You can use the following commands to show the results:

```
get router info routing-table isis
get router info isis route
```

## Default information originate option

Enabling default-information-originate generates and advertises a default route into the FortiGate unit's IS-IS-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. IS-IS does not create the default route unless you use the `always` option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into IS-IS updates.

The CLI commands associated with default information originate include:

```
config router isis
 set default-originate
end
```

## Timer options

IS-IS uses various timers to regulate its performance, including garbage, update, and timeout timers. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations. If you change these settings, ensure that the new settings are compatible with local routers and access servers.

You can configure the three IS-IS timers in the CLI, using the following commands:

```
config router isis
 set garbage-timer
 set update-timer
 set timeout-timer
end
```

You will find more information on each timer below.

### Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, or you will experience an error.

If you are experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

### Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, or you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods. It may be a considerable amount of time before the DIS is done waiting for all the timers to expire on unresponsive routes.

## Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table, which is useful if you have a very large network or if your network changes frequently.

## Authentication

In routing protocols, it is typically desirable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information about TLVs, see [TLV on page 2638](#).

Initially, IS-IS used plain cleartext to navigate the authentication rules, but this was found to be insecure since the cleartext packets were unencrypted and could be exposed to packet sniffers. As per [RFC 3567](#), HMAC-MD5 and enhanced cleartext authentication features were introduced in IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain cleartext authentication.

### HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From [RFC 2085](#):

*The “AH Key” is used as a shared secret between two communicating parties. The Key is not a “cryptographic key” as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed.”*

Cleartext authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from cleartext authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities do not compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

### Enhanced cleartext authentication

Enhanced cleartext authentication is an extension to cleartext authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authentican key chain, and allows for more simple password modification and password management. Enhanced cleartext authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

## Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, the PDU is automatically discarded.

From [RFC 5310](#):

*It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.*

## Troubleshooting IS-IS

### Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on the affected routers. The worst part is this situation will continue until the network administrator changes the router settings or the downed routers come back online.

### Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, it is possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

### How to spot a routing loop

Any time network traffic slows down, you will ask yourself if it is a network loop or not. Often slowdowns are normal. They are not a full stoppage and normal traffic resumes in a short period of time.

If the slowdown is a full halt of traffic, or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- [Checking your logs](#)
- [Using SNMP network monitoring](#)
- [Using Link Health Monitor and e-mail alerts](#)
- [Looking at the packet flow](#)

If you are not running SNMP or dead gateway detection, or if you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

## Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to **Log & Report > Log & Archive Access**. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensic analysis can better help you prepare for next time.

## Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly, as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

### To use SNMP to detect potential routing loops

1. Go to **System > Config > SNMP**.
2. Enable **SNMP Agent**.
3. Optionally enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
4. In either **SNMP v1/v2c** section or **SNMP v3** section, as appropriate, select **Create New**.
5. Enter the **Community Name** that you want to use.
6. In **Hosts**, select **Add** to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In **SNMP Event**, select the events you want to be notified about. For routing loops, this should include **CPU Overusage**, **Memory Low**, and possibly **Log disk space low**. If there are problems, the log will fill up quickly, and the FortiGate unit's resources will be overused.
9. Select **OK**.
10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically, you can configure this software to alert you about outages or CPU spikes that may indicate a routing loop.

## Using Link Health Monitor and e-mail alerts

Another tool available to you on FortiGate units is the Link Health Monitor. This is useful for dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

### To detect possible routing loops with Link Health Monitor

Use the following command to configure dead gateway detection:

```
config system link-monitor
```

```
edit "test"
 set srcintf "internal4"
 set server "8.8.8.8"
 set interval 5
 set failtime 1
end
```

Set the `Interval` (how often to send a ping) and `failtime` (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

You may also want to log CPU and memory usage, as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

### Looking at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

### Action to take on discovering a routing loop

Once you have mapped the problem on your network and determined it is in fact a routing loop, there are a number of steps to take to correct it.

1. Get any offline routers back online. This may be a simple reboot or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

### Split horizon and poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let us call them routerA, routerB, and routerC. RouterA is linked only to routerB, routerC is linked only to routerB, and routerB is linked to both routerA and routerC. To get to routerC, routerA must go through routerB. If the link to routerC goes down, it is possible that routerB will try to use routerA's route to get to routerC. This route is A-B-C, so it will not work. However, if routerB tries to use it, this begins an endless loop. This situation is called a split horizon because from routerB's point of view, the horizon stretches out in each direction but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS, this means that route is marked with a distance of 16.

## Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet. One of these routers uses OSPF and the other router uses RIP.

Your task is to configure the four FortiGates to route traffic and process network updates using IS-IS, so that the farthest FortiGate (see 'FGT4' in [Network layout and assumptions on page 2646](#)) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

Since the internal networks use OSPF and RIP, those protocols will need to be redistributed through the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

## Network layout and assumptions

## IP scheme and interfaces

- It is assumed that each FortiGate is operating in NAT mode, running FortiOS 4.0MR2+.
- All interfaces have been previously assigned and no static routes are required.
- The Authority and Format Identifier (AFI) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

## Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

## CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

### FGT1

```
config router isis
config isis-interface
edit "port3"
set circuit-type level-1
set network-type broadcast
set status enable
next
end
config isis-net
edit 1
set net 49.0048.1921.6818.2136.00
next
end
```

```
 config redistribute "connected"
 end
 config redistribute "rip"
 set status enable
 set level level-1
 end
 config redistribute "ospf"
 set status enable
 set level level-1
 end
end
config router rip
 config interface
 edit "port2"
 set receive-version 2
 set send-version 2
 next
 end
 config network
 edit 1
 set prefix 10.10.10.0 255.255.255.0
 next
 end
 config redistribute "isis"
 set status enable
 end
end
```

## FGT2

```
config router isis
 config isis-interface
 edit "port3"
 set circuit-type level-1
 set network-type broadcast
 set status enable
 next
 edit "port2"
 set network-type broadcast
 set status enable
 next
 end
 config isis-net
 edit 1
 set net 49.0048.1221.6818.2110.00
 next
 end
 set redistribute-l1 enable
 set redistribute-l2 enable
end
```

## FGT3

```
config router isis
 set is-type level-2-only
```

```

config isis-interface
 edit "wan1"
 set network-type broadcast
 set status enable
 next
 edit "dmz1"
 set network-type broadcast
 set status enable
 next
end
config isis-net
 edit 1
 set net 49.0048.1921.6818.2108.00
 next
 edit 2
 set net 49.0049.1921.6818.2108.00
 next
end
end

```

## FGT4

```

config router isis
 set is-type level-2-only
 config isis-interface
 edit "wan1"
 set network-type broadcast
 set status enable
 next
 end
 config isis-net
 edit 1
 set net 49.0049.1721.0160.1004.00
 next
 end
 config redistribute "connected"
 set status enable
 end
end

```

## Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

### Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

#### Result:

```

C 10.1.1.0/24 is directly connected, vlan1
C 10.2.2.0/24 is directly connected, vlan2
C 10.10.10.0/24 is directly connected, dmz1
R 10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07

```

```
R 10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

```
R 10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

(\*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

### Verification on FGT2, which is the border between L1 and L2 routing levels; looking at IS-IS information

```
FGT2 # get router info isis interface
```

#### Result:

```
port2 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x01
Extended Local circuit ID: 0x00000003

Number of active level-1 adjacencies: 1
Next IS-IS LAN Level-1 Hello in 2 seconds
```

```
FGT2 # get router info isis neighbor
```

#### Result:

| System Id      | Interface | SNPA           | State | Holdtime | Type | Protocol |
|----------------|-----------|----------------|-------|----------|------|----------|
| 1921.6818.2108 | port2     | 0009.0f04.0794 | Up    | 22       | L2   | IS-IS    |
| 1921.6818.2136 | port3     | 0009.0f85.acf7 | Up    | 29       | L1   | IS-IS    |

### Verification on FGT3, which is border between 2 areas, looking at IS-IS information

IS-IS router CLI commands available:

---

```
FGT3 # get router info isis ?
```

**Result:**

|              |                                |
|--------------|--------------------------------|
| interface    | show isis interfaces           |
| neighbour    | show CLNS neighbor adjacencies |
| is-neighbour | show IS neighbor adjacencies   |
| database     | show IS-IS link state database |
| route        | show IS-IS IP routing table    |
| topology     | show IS-IS paths               |

**Example of interface status and neighbors:**

```
FGT3 # get router info isis interface
```

**Result:**

```
wan1 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x01
Extended Local circuit ID: 0x00000003
Local SNPA: 0009.0f04.0794
IP interface address:
10.40.40.1/24
IPv4 interface address:
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1221.6818.2110.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-2 Hello in 3 seconds
```

```
dmz1 is up, line protocol is up
Routing Protocol: IS-IS ((null))
Network Type: Broadcast
Circuit Type: level-1-2
Local circuit ID: 0x02
Extended Local circuit ID: 0x00000005
Local SNPA: 0009.0f04.0792
IP interface address:
10.50.50.1/24
IPv4 interface address:
Level-2 Metric: 10/10, Priority: 64, Circuit ID: 1721.0160.1004.01
Number of active level-2 adjacencies: 1
Next IS-IS LAN Level-2 Hello in 7 seconds
```

```
FGT3 # get router info isis neighbor
```

**Result:**

| System Id      | Interface | SNPA           | State | Holdtime | Type | Protocol |
|----------------|-----------|----------------|-------|----------|------|----------|
| 1221.6818.2110 | wan1      | 0009.0f85.ad8c | Up    | 8        | L2   | IS-IS    |
| 1721.0160.1004 | dmz1      | 0009.0f52.7704 | Up    | 8        | L2   | IS-IS    |

**Verification on FGT4 that the remote subnets from RTR1 and RTR2 are in the routing table and learned with IS-IS**

```
FGT4 # get router info routing-table all
```

**Result:**

```

```

## Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

...to stop the debug type output:

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

## Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also, RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate units support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate unit interface is connected. Multicast routing is not supported in transparent mode (TP mode).

To support PIM communications, the sending/receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. In addition, if a FortiGate unit is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate unit, the FortiGate unit can perform any of these functions at any time as configured.

## Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate unit interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following CLI commands to configure IPv6 PIM sparse multicast routing:

```
config router multicast6
 set multicast-routing {enable | disable}
 config interface
 edit <interface-name>
 set hello-interval <1-65535 seconds>
 set hello-holdtime <1-65535 seconds>
 end
 config pim-sm-global
 config rp-address
 edit <index>
 set ipv6-address <ipv6-address>
 end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

## Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information, if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM

routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers. PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate units operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate unit to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

## PIM support

A FortiGate unit can be configured to support PIM by going to **Network > Multicast** and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI command. When PIM is enabled, the FortiGate unit allocates memory to manage mapping information. The FortiGate unit communicates with neighboring PIM routers to acquire mapping information and if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio and video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end user can type in a class D multicast group address, an alias for the multicast group address, or a conference call number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them. End users may use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there is no way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end-users may switch to a different multicast address).

### To configure a PIM domain

1. If you will be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you will be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate units, use the `config router multicast` command to set global operating parameters.

5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interface(s).

## Multicast forwarding and FortiGate units

In both transparent mode and NAT mode, you can configure FortiGate units to forward multicast traffic.

For a FortiGate unit to forward multicast traffic, you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that is accepted, based on source and destination address, and to perform NAT on multicast packets.

In the example shown below, a multicast source on the marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate unit, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate unit is not acting as a multicast router.

## Multicast forwarding and RIPv2

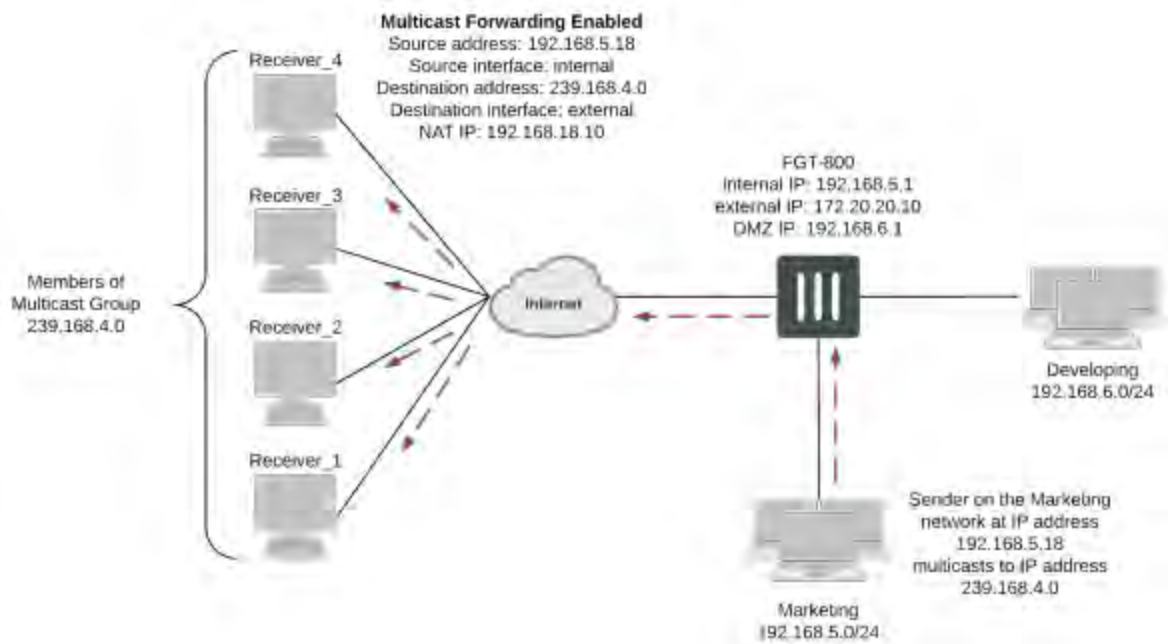

RIPv2 uses multicast to share routing table information. If your FortiGate unit is installed on a network that includes RIPv2 routers, you must configure the FortiGate unit to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate unit. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate unit to forward multicast packets.

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate unit, you can add standard security policies. Security policies to accept RIPv1 packets can use the ALL predefined firewall service or the RIP predefined firewall service.

---

### Example multicast network including a FortiGate unit that forwards multicast packets

## Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding from the CLI. Two steps are required:

1. Adding multicast security policies
2. Enabling multicast forwarding

This second step is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There is sometimes confusion between the terms “forwarding” and “routing”. These two functions should not be taking place at the same time.

It is mentioned that multicast-forward should be enabled when the FortiGate unit is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter should **NOT** be enabled when the FortiGate unit operates as a multicast router (for example, with a routing protocol enabled. It should only be enabled when there is no routing protocols activated.

## Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and, optionally, the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and destination interfaces are optional. If left blank, the multicast will be forwarded to ALL interfaces.
- Source and destination addresses are optional. If left unset, it means ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

## Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, the FortiGate unit forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

---

Enter the following CLI command to enable multicast forwarding:

```
config system settings
 set multicast-forward enable
end
```

If multicast forwarding is disabled and the FortiGate unit drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate unit does not increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
 set multicast-ttl-notchange enable
end
```

In transparent mode, the FortiGate unit does not forward frames with multicast destination addresses. Multicast traffic, such as the one used by routing protocols or streaming media, may need to traverse the FortiGate unit and should not interfere with the communication. To avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

The CLI parameter `multicast-skip-policy` must be disabled when using multicast security policies. To disable enter the commands:

```
config system settings
 set multicast-skip-policy disable
end
```

---

In this simple example, no check is performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

**To enable the multicast policy**

```
config firewall multicast-policy
edit 1
set action accept
end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

**To enable the restrictive multicast policy**

```
config firewall multicast-policy
edit 1
set srcintf wan1
set dstintf internal
set action accept
end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129, which is represented by the address object "example\_addr-1".

**To enable the restrictive multicast policy**

```
config firewall multicast-policy
edit 1
set srcintf wan1
set srcaddr example_addr-1
set dstintf internal
set action accept
end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0. The policy allows the multicast packets to enter the internal interface and then exit the external interface. When the packets leave the external interface, their source address is translated to 192.168.18.10

```
config firewall multicast-policy
edit 5
set srcaddr 192.168.5.18 255.255.255.255
set srcintf internal
set destaddr 239.168.4.0 255.255.255.0
set dstintf external
set nat 192.168.18.10
end
```

This example shows how to configure a multicast security policy so that the FortiGate unit forwards multicast packets from a multicast server with an IP 10.10.10.10 is broadcasting to address 225.1.1.1. This server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
edit 1
 set srcintf DMZ
 set srcaddr 10.10.10.10 255.255.255.255
 set dstintf Internal
 set dstaddr 225.1.1.1 255.255.255.255
 set action accept
edit 2
 set action deny
end
```

### Displaying IPv6 multicast router information

You can use the following CLI command to display IPv6 multicast router information (equivalent to the IPv4 version of the command):

```
get router info6 multicast
```

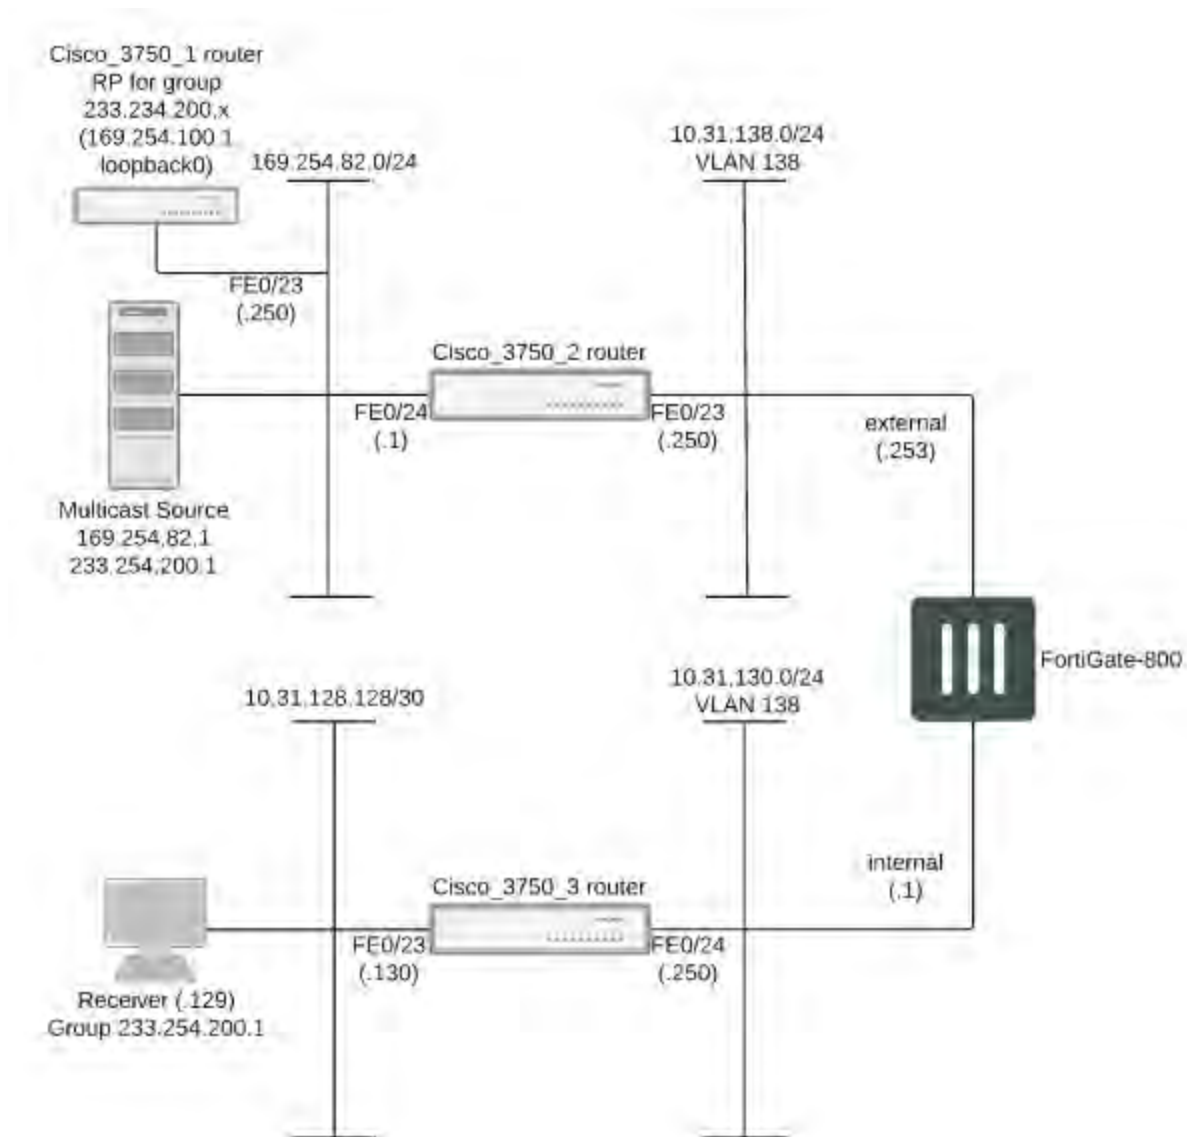

## Multicast routing examples

This section contains the following multicast routing configuration examples and information:

- Example FortiGate PIM-SM configuration using a static RP
- FortiGate PIM-SM debugging examples
- Example multicast destination NAT (DNAT) configuration
- Example PIM configuration that uses BSR to find the RP

### Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown below has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

**Example: FortiGate PIM-SM topology**

The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco\_3750\_1. Using a bootstrap router (BSR) was not tested in this example. See "Example PIM configuration that uses BSR to find the RP" for an example that uses a BSR.

**Configuration steps**

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- Cisco\_3750\_1 router configuration
- Cisco\_3750\_2 router configuration
- To configure the FortiGate-800 unit
- Cisco\_3750\_3 router configuration

**Cisco\_3750\_1 router configuration**

```
version 12.2
!

### To configure the FortiGate-800 unit

1. Configure the internal and external interfaces.

- **Internal**

Go to **Network > Interfaces**.

Select the internal interface.

Verify the following settings:

|                               |                             |
|-------------------------------|-----------------------------|
| <b>Type:</b>                  | Physical Interface          |
| <b>Addressing mode:</b>       | Manual                      |
| <b>IP/Network Mask:</b>       | 10.31.138.253 255.255.255.0 |
| <b>Administrative Access:</b> | PING                        |

Select **OK**.

- **External**

Go to **Network > Interfaces**.  
Select the external interface.

Verify the following settings:

|                               |                             |
|-------------------------------|-----------------------------|
| <b>Type:</b>                  | Physical Interface          |
| <b>Addressing mode:</b>       | Manual                      |
| <b>IP/Network Mask:</b>       | 10.31.130.253 255.255.255.0 |
| <b>Administrative Access:</b> | HTTPS and PING              |

Select **OK**.

2. Add a firewall addresses.

Go to **Policy & Objects > Addresses**.

- RP

Select **Create New**.

Use the following settings:

|                        |                  |
|------------------------|------------------|
| <b>Category</b>        | Address          |
| <b>Name</b>            | RP               |
| <b>Type</b>            | Subnet           |
| <b>Subnet/IP Range</b> | 169.254.100.1/32 |
| <b>Interface</b>       | Any              |
| <b>Visibility</b>      | <enabled>        |

Select **OK**.

- Multicast source subnet

Select **Create New**.

Use the following settings:

|                 |                         |
|-----------------|-------------------------|
| <b>Category</b> | Address                 |
| <b>Name</b>     | multicast_source_subnet |

|                        |                 |
|------------------------|-----------------|
| <b>Type</b>            | Subnet          |
| <b>Subnet/IP Range</b> | 169.254.82.0/24 |
| <b>Interface</b>       | Any             |
| <b>Visibility</b>      | <enabled>       |

Select **OK**.

**3. Add destination multicast address**

Go to **Policy & Objects > Addresses**.

Select **Create New**.

Use the following settings:

|                         |                   |
|-------------------------|-------------------|
| <b>Category</b>         | Multicast Address |
| <b>Name</b>             | Multicast_stream  |
| <b>Type</b>             | Broadcast Subnet  |
| <b>Broadcast Subnet</b> | 233.254.200.0/24  |
| <b>Interface</b>        | Any               |
| <b>Visibility</b>       | <enabled>         |

Select **OK**.

**4. Add standard security policies to allow traffic to reach the RP.**

Go to **Policy & Objects > IPv4 Policy**.

- 1st policy

Select **Create New**.

Use the following settings:

|                            |          |
|----------------------------|----------|
| <b>Incoming Interface</b>  | internal |
| <b>Source Address</b>      | all      |
| <b>Outgoing Interface</b>  | external |
| <b>Destination Address</b> | RP       |
| <b>Schedule</b>            | always   |

|                |        |
|----------------|--------|
| <b>Service</b> | ALL    |
| <b>Action</b>  | ACCEPT |

Select **OK**.

- 2nd policy

Select **Create New**

Use the following settings:

|                            |          |
|----------------------------|----------|
| <b>Incoming Interface</b>  | external |
| <b>Source Address</b>      | RP       |
| <b>Outgoing Interface</b>  | internal |
| <b>Destination Address</b> | all      |
| <b>Schedule</b>            | always   |
| <b>Service</b>             | ALL      |
| <b>Action</b>              | ACCEPT   |

Select **OK**.

5. Add the multicast security policy.

Go to **Policy & Objects > Multicast Policy**.

Select **Create New**.

Use the following settings:

|                            |                         |
|----------------------------|-------------------------|
| <b>Incoming Interface</b>  | external                |
| <b>Source Address</b>      | multicast_source_subnet |
| <b>Outgoing Interface</b>  | internal                |
| <b>Destination Address</b> | multicast_stream        |
| <b>Protocol</b>            | Any                     |
| <b>Action</b>              | ACCEPT                  |

Select **OK**.

6. Add an access list. (CLI only)

```
config router access-list
```

```

edit Source-RP
config rule
edit 1
set prefix 233.254.200.0 255.255.255.0
set exact-match disable
next
end

```

## 7. Add some static routes.

Go to **Network > Static Routes**.

- Route 1

Select **Create New**.

Use the following settings:

|                                |                 |
|--------------------------------|-----------------|
| <b>Destination IP/Mask</b>     | 0.0.0.0/0.0.0.0 |
| <b>Gateway</b>                 | 10.31.130.250   |
| <b>Interface</b>               | internal        |
| <b>Administrative Distance</b> | <default>       |
| <b>Priority</b>                | <default>       |

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

|                                |                |
|--------------------------------|----------------|
| <b>Destination IP/Mask</b>     | 169.254.0.0/16 |
| <b>Gateway</b>                 | 10.31.138.250  |
| <b>Interface</b>               | external       |
| <b>Administrative Distance</b> | <default>      |
| <b>Priority</b>                | <default>      |

Select **OK**.

## 8. Configure multicast routing.

Go to **Network > Multicast**.

Add the following Static Rendezvous Point(s):

- 169.254.100.1
- Route 1

Select **Create New**.

Use the following settings:

|                              |                               |
|------------------------------|-------------------------------|
| <b>Interface</b>             | internal                      |
| <b>PIM Mode</b>              | Sparse Mode                   |
| <b>DR Priority</b>           | <not needed in this scenario> |
| <b>RP Candidate</b>          | <not needed in this scenario> |
| <b>RP Candidate Priority</b> | <not needed in this scenario> |

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

|                              |             |
|------------------------------|-------------|
| <b>Interface</b>             | external    |
| <b>PIM Mode</b>              | Sparse Mode |
| <b>DR Priority</b>           |             |
| <b>RP Candidate</b>          |             |
| <b>RP Candidate Priority</b> |             |

Select **OK**.

### Cisco\_3750\_3 router configuration

```

permit 233.254.200.0 0.0.0.255

```

## FortiGate PIM-SM debugging examples

Using the example topology shown below, you can trace the multicast streams and states within the three FortiGate units (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from the FortiGate unit when the multicast stream is flowing correctly from source to receiver.

### PIM-SM debugging topology

### Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```

FGT-3 # get router info multicast igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
239.255.255.1 port3 00:31:15 00:04:02 10.167.0.62

```

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active, the expire time should drop to approximately 2 minutes before being refreshed.

### Checking the PIM-SM neighbors

Next, the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3:

```
FGT-3 # get router info multicast pim sparse-mode neighbour
Neighbor Interface Uptime/Expires Ver DR
Address Priority/Mode
10.132.0.156 port2 01:57:12/00:01:33 v2 1 /
```

### Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the \*, G join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
RP: 192.168.1.1
Uptime: 07:23:00
```

### Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

|                          |                                                                                                                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>(*,*,RP) Entries</b>  | This state may be reached by general joins for all groups served by a specified RP.                                                                                                                              |
| <b>(*,G) Entries</b>     | State that maintains the RP tree for a given group.                                                                                                                                                              |
| <b>(S,G) Entries</b>     | State that maintains a source-specific tree for source S and group G.                                                                                                                                            |
| <b>(S,G,rpt) Entries</b> | State that maintains source-specific information about source s on the RP tree for G. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree. |
| <b>FCR</b>               | The FCR state entries are for tracking the sources in the <*, G> when <S, G> is not available for any reason, the stream would typically be flowing when this state exists.                                      |

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: JOINED
Local:
port3
Joined:
Asserted:
FCR:
```

The RP will always be listed in a \*, G entry, the RPF neighbor and interface index will also be shown. In this topology these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
Asserted:
Outgoing:
port3
```

This is the entry for the SPT, no RP IS listed. The S, G stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
Local:
Pruned:
Outgoing:
```

The above S, G, RPT state is created for all streams that have both a S, G and a \*, G entry on the router. This is not pruned, in this case, because of the topology: the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN, which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

### Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams.

```
FGT-3 # get router info multicast pim sparse-mode next-hop
Flags: N = New, R = RP, S = Source, U = Unreachable
Destination Type Nexthop Nexthop Nexthop Metric Pref Refcnt
Num Addr Ifindex

10.166.0.11 ..S. 1 10.132.0.156 9 21 110 3
192.168.1.1 .R.. 1 10.132.0.156 9 111 110 2
```

## Viewing the PIM multicast forwarding table

Also, you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
Incoming interface: port2
Outgoing interface list:
port3 (TTL threshold 1)
```

## Viewing the kernel forwarding table

Also, the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[] status=resolved
last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
index(ttl)=[6(1),]
```

## Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2, there are some small differences:

```
FGT-2 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: JOINED
Local:
Joined:
external
Asserted:
FCR:
```

The \*, G entry now has a joined interface rather than local because it has received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
```

```

Local:
Joined:
external
Asserted:
Outgoing:
external

```

The S, G entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```

(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
Local:
Pruned:
Outgoing:
External

```

The S, G, RPT is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

### Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states. There is no \*, G entry because it is not in the path of a receiver and the RP.

```

FGT-1_master # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

```

Below the S, G is the SPT termination because this FortiGate unit is the first hop router. The RPF neighbor always shows as 0.0.0.0 because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```

(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
Asserted:
Outgoing:
external

```

The stream has been pruned back from the RP because the end-to-end SPT is flowing. In this case, there is no requirement for the stream to be sent to the RP.

```

(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external
Upstream State: RPT NOT JOINED

```

Local:  
Pruned:  
Outgoing:

## Example multicast DNAT configuration

The example topology shown and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example, the FortiGate units have the following roles:

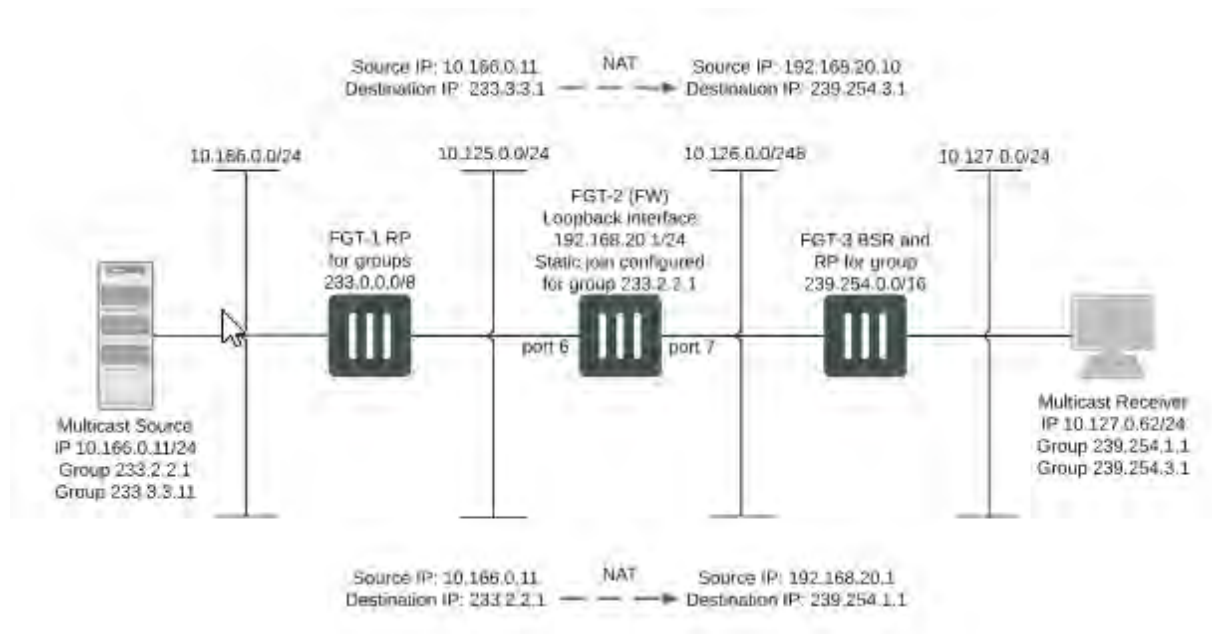

- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1, FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1, FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

## Example multicast DNAT topology

## To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named `loopback`.

```
config system interface
edit loopback
```

```

 set vdom root
 set ip 192.168.20.1 255.255.255.0
 set type loopback
 next
end

```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also, add static joins to the loopback interface for any groups to be translated.

```

config router multicast
config interface
edit loopback
 set pim-mode sparse-mode
 config join-group
 edit 233.2.2.1
 next
 edit 233.3.3.1
 next
 end
next

```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```

config firewall ippool
edit Multicast_source
 set endip 192.168.20.20
 set interface port6
 set startip 192.168.20.10
next
end

```

4. Add the translation security policies.

Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool. The source and destination addresses will need to be previously created address objects. For this example, 233.3.3.1 255.255.255.255 will be represented by "example-addr\_1" and 10.166.0.11 255.255.255.255 will be represented by "example-addr\_2". You will likely want to use something more intuitive from your own network.

```

config firewall multicast-policy
edit 1
 set dnat 239.254.3.1
 set dstaddr example-addr_1
 set dstintf loopback
 set nat 192.168.20.10
 set srcaddr example-addr_2
 set srcintf port6
next
edit 2
 set dnat 239.254.1.1
 set dstaddr 233.2.2.1 255.255.255.255
 set dstintf loopback
 set nat 192.168.20.1
 set srcaddr 10.166.0.11 255.255.255.255
 set srcintf port6
next
end

```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate unit.

```
config firewall multicast-policy
 edit 3
 set dstintf port7
 set srcintf loopback
 next
end
```

### Example PIM configuration that uses BSR to find the RP

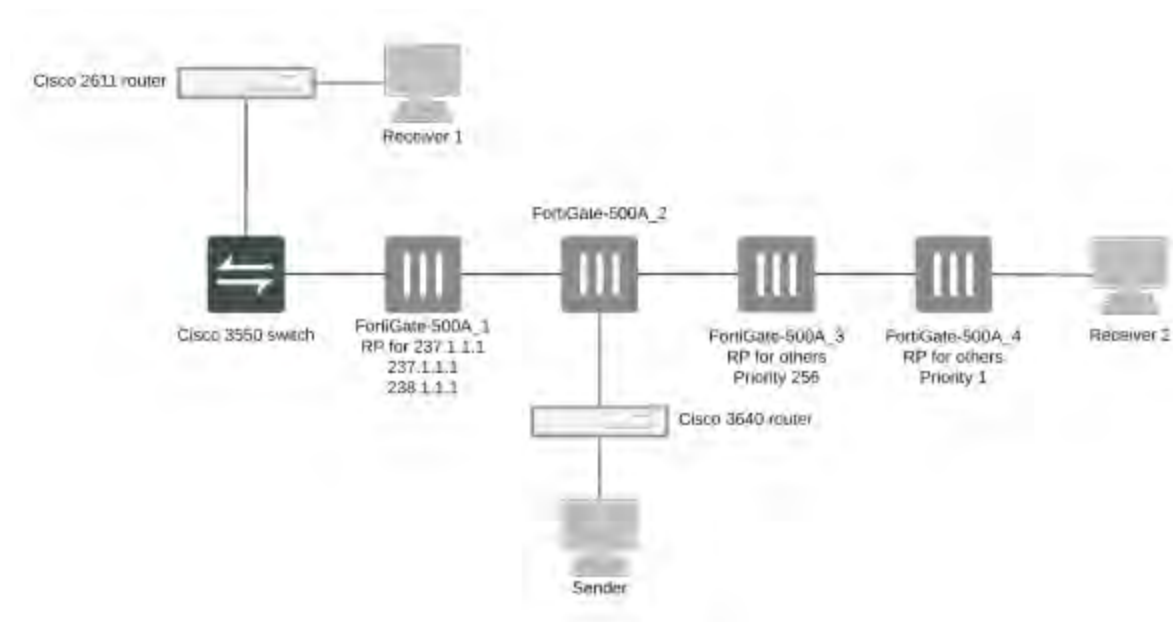

This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A units (FortiGate-500A\_1 to FortiGate-500A\_4). A multicast sender is connected to FortiGate-500A\_2. FortiGate-500A\_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

This example describes:

- Commands used in this example
- Configuration steps
- Example debug commands

### PIM network topology using BSR to find the RP

### Commands used in this example

This example uses CLI commands for the following configuration settings:

- Adding a loopback interface (lo0)
- Defining the multicast routing
- Adding the NAT multicast policy

### Adding a loopback interface

Where required, the following command is used to define a loopback interface named lo0.

```
config system interface
 edit lo0
 set vdom root
 set ip 1.4.50.4 255.255.255.255
 set allowaccess ping https ssh snmp http telnet
 set type loopback
 next
end
```

### Defining the multicast routing

In this example, the following command syntax is used to define multicast routing.

The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface lo0 must join the 236.1.1.1 group (source).

```
config router multicast
 config interface
 edit port6
 set pim-mode sparse-mode
 next
 edit port1
 set pim-mode sparse-mode
 next
 edit lo0
 set pim-mode sparse-mode
 set rp-candidate enable
 config join-group
 edit 236.1.1.1
 next
 end
 set rp-candidate-priority 1
 next
end
set multicast-routing enable
config pim-sm-global
 set bsr-allow-quick-refresh enable
 set bsr-candidate enable
 set bsr-interface lo0
 set bsr-priority 200
end
end
```

### Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation.

The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
 edit 1
 set dstintf port6
 set srcintf lo0
 next
 edit 2
 set dnat 238.1.1.1
 set dstintf lo0
 set nat 1.4.50.4
 set srcintf port1
 next
```

### Configuration steps

In this sample, FortiGate-500A\_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A\_4 is the RP for the other group which has a priority of 1. OSPF is used in this example to distribute routes including the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A\_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A\_4 configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well

The following procedures include the CLI commands for configuring each of the FortiGate units in the example configuration.

### To configure FortiGate-500A\_1

#### 1. Configure multicast routing:

```
config router multicast
 config interface
 edit port5
 set pim-mode sparse-mode
 next
 edit port4
 set pim-mode sparse-mode
 next
 edit lan
 set pim-mode sparse-mode
 next
 edit port1
 set pim-mode sparse-mode
 next
 edit lo999
 set pim-mode sparse-mode
 next
 edit lo0
 set pim-mode sparse-mode
 set rp-candidate enable
 set rp-candidate-group 1
 next
 end
 set multicast-routing enable
 config pim-sm-global
```

```

 set bsr-candidate enable
 set bsr-interface lo0
 end
end

```

## 2. Add multicast security policies:

```

config firewall multicast-policy
 edit 1
 set dstintf port5
 set srcintf port4
 next
 edit 2
 set dstintf port4
 set srcintf port5
 next
 edit 3
 next
end

```

## 3. Add router access lists:

```

config router access-list
 edit 1
 config rule
 edit 1
 set prefix 228.1.1.1 255.255.255.255
 set exact-match enable
 next
 edit 2
 set prefix 237.1.1.1 255.255.255.255
 set exact-match enable
 next
 edit 3
 set prefix 238.1.1.1 255.255.255.255
 set exact-match enable
 next
 end
 next
end

```

## To configure FortiGate-500A\_2

### 1. Configure multicast routing:

```

config router multicast
 config interface
 edit "lan"
 set pim-mode sparse-mode
 next
 edit "port5"
 set pim-mode sparse-mode
 next
 edit "port2"
 set pim-mode sparse-mode
 next
 edit "port4"
 set pim-mode sparse-mode
 next
 end
end

```

```
edit "lo_5"
 set pim-mode sparse-mode
 config join-group
 edit 236.1.1.1
 next
 end
next
end
set multicast-routing enable
end
```

### 2. Add multicast security policies:

```
config firewall multicast-policy
edit 1
 set dstintf lan
 set srcintf port5
next
edit 2
 set dstintf port5
 set srcintf lan
next
edit 4
 set dstintf lan
 set srcintf port2
next
edit 5
 set dstintf port2
 set srcintf lan
next
edit 7
 set dstintf port1
 set srcintf port2
next
edit 8
 set dstintf port2
 set srcintf port1
next
edit 9
 set dstintf port5
 set srcintf port2
next
edit 10
 set dstintf port2
 set srcintf port5
next
edit 11
 set dnat 237.1.1.1
 set dstintf lo_5
 set nat 5.5.5.5
 set srcintf port2
next
edit 12
 set dstintf lan
 set srcintf lo_5
next
edit 13
 set dstintf port1
```

```

 set srcintf lo_5
 next
 edit 14
 set dstintf port5
 set srcintf lo_5
 next
 edit 15
 set dstintf port2
 set srcintf lo_5
 next
 edit 16
 next
end

```

## To configure FortiGate-500A\_3

### 1. Configure multicast routing:

```

config router multicast
 config interface
 edit port5
 set pim-mode sparse-mode
 next
 edit port6
 set pim-mode sparse-mode
 next
 edit lo0
 set pim-mode sparse-mode
 set rp-candidate enable
 set rp-candidate-priority 255
 next
 edit lan
 set pim-mode sparse-mode
 next
 end
set multicast-routing enable
config pim-sm-global
 set bsr-candidate enable
 set bsr-interface lo0
end
end

```

### 2. Add multicast security policies:

```

config firewall multicast-policy
 edit 1
 set dstintf port5
 set srcintf port6
 next
 edit 2
 set dstintf port6
 set srcintf port5
 next
 edit 3
 set dstintf port6
 set srcintf lan
 next
 edit 4
 set dstintf lan

```

```
 set srcintf port6
 next
 edit 5
 set dstintf port5
 set srcintf lan
 next
 edit 6
 set dstintf lan
 set srcintf port5
 next
end
```

## To configure FortiGate-500A\_4

### 1. Configure multicast routing:

```
config router multicast
 config interface
 edit port6
 set pim-mode sparse-mode
 next
 edit lan
 set pim-mode sparse-mode
 next
 edit port1
 set pim-mode sparse-mode
 next
 edit lo0
 set pim-mode sparse-mode
 set rp-candidate enable
 config join-group
 edit 236.1.1.1
 next
 end
 set rp-candidate-priority 1
 next
 end
 set multicast-routing enable
 config pim-sm-global
set bsr-allow-quick-refresh enable
 set bsr-candidate enable
 set bsr-interface lo0
 set bsr-priority 1
 end
end
```

### 2. Add multicast security policies:

```
config firewall policy
 edit 1
 set srcintf lan
 set dstintf port6
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
 next
 edit 2
```

```
 set srcintf port6
 set dstintf lan
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 3
 set srcintf port1
 set dstintf port6
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 4
 set srcintf port6
 set dstintf port1
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 5
 set srcintf port1
 set dstintf lan
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 6
 set srcintf lan
 set dstintf port1
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 7
 set srcintf port1
 set dstintf port1
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
next
edit 8
 set srcintf port6
 set dstintf lo0
 set srcaddr all
```

```

 set dstaddr all
 set action accept
 set schedule always
 set service ALL
 next
 edit 9
 set srcintf port1
 set dstintf lo0
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
 next
 edit 10
 set srcintf lan
 set dstintf lo0
 set srcaddr all
 set dstaddr all
 set action accept
 set schedule always
 set service ALL
 next
end

```

## Troubleshooting

### Netflow support

Netflow is a networking feature, introduced by Cisco, to collect and export information about traffic flow through routers. IPFIX (Internet Protocol Flow Information Export) is the standardized Internet Protocol based on NetFlow version 9. The standards requirements for IPFIX are outlined in RFC 3197, and its basic specifications and other information are documented in RFC 5103, RFC 6759, and RFC 7011 through RFC 7015.

You can enable and configure NetFlow traffic, using the following CLI commands:

```

config system netflow
 set collector-ip <collector IP>
 set collector-port <NetFlow collector port>
 set csource-ip <Source IP for NetFlow agent>
 set cactive-flow-timeout <time in minutes of timeout to report active flows>
 set cinactive-flow-timeout <time in seconds of timeout for periodic report of finished flows>
end

```

You can also configure these settings per VDOM, using the following CLI command:

```

config system vdom-netflow

```

You must also enable a Netflow sampler on specific interfaces.

## Using sFlow to monitor network traffic

FortiGate includes support for sFlow, a monitoring solution that uses packet sampling to monitor network traffic. You can use sFlow to identify issues in your organization's network that might impact performance. Because the packet information that sFlow collects and sends is only a sampling of your network data, it has minimal impact on the performance of your network.

The sFlow solution consists of the following components:

- **sFlow Agent:** Collects packet information, such as packet flow samples and interface counters
- **sFlow Datagrams:** Contains the packet information
- **sFlow Collector:** Analyzes the packet information and provides real-time reporting on your network traffic

The sFlow Agent is embedded in the FortiGate. After you configure sFlow on a FortiGate, the sFlow Agent captures packet information, combines the information into sFlow Datagrams, and sends them to the sFlow Collector. The sFlow Collector analyzes the sFlow Datagrams and presents the information so that you can see the source of potential traffic issues. The FortiGate doesn't act as an sFlow Collector. sFlow Collector software is available from third-party software vendors.

The sFlow Agent performs packet sampling on packets that arrive on a FortiGate interface to determine which ones to copy and send to the sFlow Collector. The packet information sFlow collects depends on the type of FortiGate interface. If you enable sFlow on an internal interface, when the interface receives packets from devices with private IP addresses, the packet information that sFlow collects includes the private IP addresses. If you enable sFlow on an external (WAN) interface, when the interface receives packets to route to or from the Internet, the packet information that sFlow collects includes the IP address of the WAN interface as the source or destination interface, depending on the direction of the traffic. It doesn't include IP addresses that are NAT'd (Network Address Translation) on another interface.

sFlow Datagrams contain the following information:

- Packet headers, such as MAC, IPv4, and TCP
- Sample process parameters, such as rate and pool
- Input and output ports
- Priority (802.1p and ToS)
- VLAN (802.1Q)
- Source prefixes, destination prefixes, and next hop addresses
- BGP source AS, source peer AS, destination peer AS, communities, and local preference
- User IDs (TACACS, RADIUS) for source and destination
- URL associated with source and destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

FortiOS implements sFlow version 5. For more information about sFlow, sFlow Collector software, and sFlow MIBs, visit [www.sflow.org](http://www.sflow.org).

## Configuring sFlow on a FortiGate

You can configure sFlow globally, for VDOMs, or for interfaces on a FortiGate. When you configure sFlow for an interface, you can configure the rate that the sFlow Agent samples traffic and the direction of that traffic. You can also set the frequency that the sFlow Agent sends sFlow Datagrams to the sFlow Collector.

You configure sFlow in the FortiGate CLI, by performing the following tasks:

1. Configure destination information for sFlow Datagrams. This also configures sFlow globally on the FortiGate.
2. Optionally, configure sFlow for one of the following:
  - A virtual domain (VDOM)
  - An interface

### Prerequisites

- Install and configure an sFlow Collector

### Configure destination information for sFlow Datagrams – CLI:

```
config system sflow
 set collector-ip <ipv4_address>
 set collector-port <port_number>
 set source-ip <ipv4_address>
end
```

where you set the following variables:

| CLI option     | Description                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| collector-ip   | The IPv4 address of the sFlow Collector                                                                                                                                                                                                                                     |
| collector-port | The UDP port number that the sFlow Agent on the FortiGate uses to send sFlow Datagrams to the sFlow Collector. The default value is 6343.<br><br>Don't change this setting unless the sFlow Collector or network configuration requires you to change it.                   |
| source-ip      | The source IPv4 address that the FortiGate uses to send sFlow Datagrams to the sFlow Collector<br><br>This setting is optional. If you don't configure a source IP address, the FortiGate uses the source IP address of the port through which it sends the sFlow Datagram. |

### Configure sFlow for a VDOM – CLI:

When you configure sFlow for a VDOM, you specify the sFlow Collector that the VDOM will use. To have the VDOM use the sFlow Collector that's configured globally on the FortiGate, don't enter values for the collector-ip and collector-port options. To have the VDOM use a different sFlow collector, enter values for these options.

```
config system vdom-sflow
 set vdom-sflow enable
 set collector-ip <ipv4_address>
 set collector-port <port_number>
 set source-ip <ipv4_address>
end
```

where you set the following variables:

| CLI option   | Description                             |
|--------------|-----------------------------------------|
| collector-ip | The IPv4 address of the sFlow Collector |

| CLI option                  | Description                                                                                                                                                                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collector-port</code> | <p>The UDP port number that the sFlow Agent on the FortiGate uses to send sFlow Datagrams to the sFlow Collector. The default value is 6343.</p> <p>Don't change this setting unless the sFlow Collector or network configuration requires you to change it.</p>                   |
| <code>source-ip</code>      | <p>The source IPv4 address that the FortiGate uses to send sFlow Datagrams to the sFlow Collector</p> <p>This setting is optional. If you don't configure a source IP address, the FortiGate uses the source IP address of the port through which it sends the sFlow Datagram.</p> |

### Configure sFlow for an interface – CLI:

sFlow is supported on various FortiGate interfaces, including physical, VLAN, and aggregate interfaces. However, sFlow isn't supported on some virtual interfaces, such as VDOM link, IPsec, GRE, and SSL interfaces.

When you configure sFlow on an interface, you can set the rate that the sFlow Agent samples traffic on the interface, the direction of that traffic, and the frequency that the sFlow Agent sends sFlow Datagrams to the sFlow Collector.

If sFlow is configured for a VDOM that the interface belongs to, the sFlow Agent sends sFlow Datagrams to the sFlow Collector that's configured for the VDOM. Otherwise, the sFlow Datagrams are sent to the sFlow Collector that's configured globally on the FortiGate.

Configuring sFlow for an interface disables all NP4 and NP6 offloading for all traffic on that interface.

```
config system interface
 edit <interface_name>
 set sflow-sampler enable
 set sample-rate <rate>
 set sample-direction {tx | rx | both}
 set polling-interval <interval>
 next
end
```

where you set the following variables:

| CLI option               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sample-rate</code> | <p>The average number of packets that the sFlow Agent lets pass before taking a sample. The range is 10 to 99999. The default is 2000.</p> <p>For example, if you set this to 1000, the sFlow Agent samples 1 out of every 1000 packets.</p> <p>If you set a lower rate, the sFlow Agent samples a higher number of packets, which increases the accuracy of the sampling data. However, this also increases the amount of CPU resources and network bandwidth that sFlow uses.</p> <p>In most cases, the default sample rate of 2000 provides enough accuracy.</p> |

| CLI option       | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sample-direction | <p>The direction of the traffic that the sFlow Agent samples:</p> <ul style="list-style-type: none"> <li>• <b>tx</b>: Samples the traffic that the interface sends</li> <li>• <b>rx</b>: Samples the traffic that the interface receives</li> <li>• <b>both</b>: Samples the traffic that the interface sends and receives</li> </ul>                                                                        |
| polling-interval | <p>The amount of time, in seconds, that the sFlow Agent waits between sending sFlow Datagrams to the sFlow Collector. The range is 1 to 255 seconds. The default is 20 seconds.</p> <p>If you set a higher polling interval, the sFlow Agent sends less data across your network, but the sFlow Collector's view of your network won't be as up-to-date as it would if you set a lower polling interval.</p> |

## Packet capture

When troubleshooting networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing.

### To use the packet capture:

1. Go to **Network > Packet Capture**.
2. Select **Create New** or select an existing entry if you have already made one that fits your needs.
3. Select the interface to monitor and select the number of packets to keep.
4. Select **Enable Filters**.
5. Enter the information you want to gather from the packet capture.
6. Select **OK**.

To run the capture, select the play button in the progress column in the packet capture list. If not active, **Not Running** will also appear in the column cell. The progress bar will indicate the status of the capture. You can stop and restart it at any time.

When the capture is complete, select the **Download** icon to save the packet capture file to your hard disk for further analysis.

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- Finding missing traffic
- Seeing if sessions are setting up properly
- Locating ARP problems such as broadcast storm sources and causes
- Confirming which address a computer is using on the network if they have multiple addresses or are on multiple networks
- Confirming routing is working as you expect
- Wireless client connection problems
- Intermittent missing PING packets
- A particular type of packet is having problems, such as UDP, which is commonly used for streaming video

If you are running a constant traffic application, such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate unit, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT, or other configuration, is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you are looking for. Capture is used to confirm or deny your ideas about what is happening on the network. If you try capture without a plan to narrow your search, you could end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you are looking for.

# Chapter 22 - Parallel Path Processing - Life of a Packet

## Parallel path processing - life of a packet

Directed by security policies, a FortiGate screens network traffic from the IP layer up through the application layer of the TCP/IP stack. The steps involved in this inspection depend on the FortiGate hardware configuration (the presence or absence of network processors such as the NP6 and content processors such as the CP8 and CP9) and on the Unified Threat Management (UTM)/Next Generation Firewall (NGFW) inspection mode (flow-based or proxy-based) of the FortiGate or VDOM.

This chapter describes what happens to a packet as it travels through a FortiGate running FortiOS 6.0.

The FortiGate performs three types of security inspection:

- Kernel-based stateful inspection, that provides individual packet-based security within a basic session state
- Flow-based inspection, that takes a snapshot of content packets and uses pattern matching to identify security threats in the content
- Proxy-based inspection, that reconstructs content passing through the FortiGate and inspects the content for security threats.

Each inspection component plays a role in the processing of a packet as it traverses the FortiGate en route to its destination.

## Parallel Path Processing

Parallel Path Processing (PPP) uses the firewall policy configuration to choose from a group of parallel options to determine the optimal path for processing a packet. Most FortiOS features are applied through Firewall policies and the features applied determine the path a packet takes. Using firewall policies you can impose UTM/NGFW processing on content traffic that may contain security threats (such as HTTP, email and so on). Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors. Using the policy configuration you can apply a range of protection from basic IPS attack protection that looks for network-based attacks to full scale advanced threat management (ATM), application control, antivirus, DLP and so on.

You can also create policies for traffic that does not pose security threats and bypass UTM/NGFW checking. This control allows you to improve network performance without compromising security. On FortiGate with network processors (for example the NP6) much of the traffic that does not require UTM/NGFW processing can be offloaded to the NP6 processors freeing up FortiGate processing resources for other higher risk traffic.

In addition, many FortiGate models support NTurbo to offload flow-based UTM/NGFW sessions to network processors. Flow-based sessions can also be accelerated using IPSA technology to enhance offloading of pattern matching to CP8 and CP9 content processors.

This chapter begins with an overview of packet flow ingress and egress and includes a section that shows how NP6 offloading optimizes packet flow for packets that don't require UTM/NGFW processing and for packets that use NTurbo to offload flow-based UTM/NGFW processing.

Next this chapter breaks down how packets pass through UTM/NGFW processing both for a single-pass flow-based UTM/NGFW processing and a proxy-based UTM/NGFW processing.

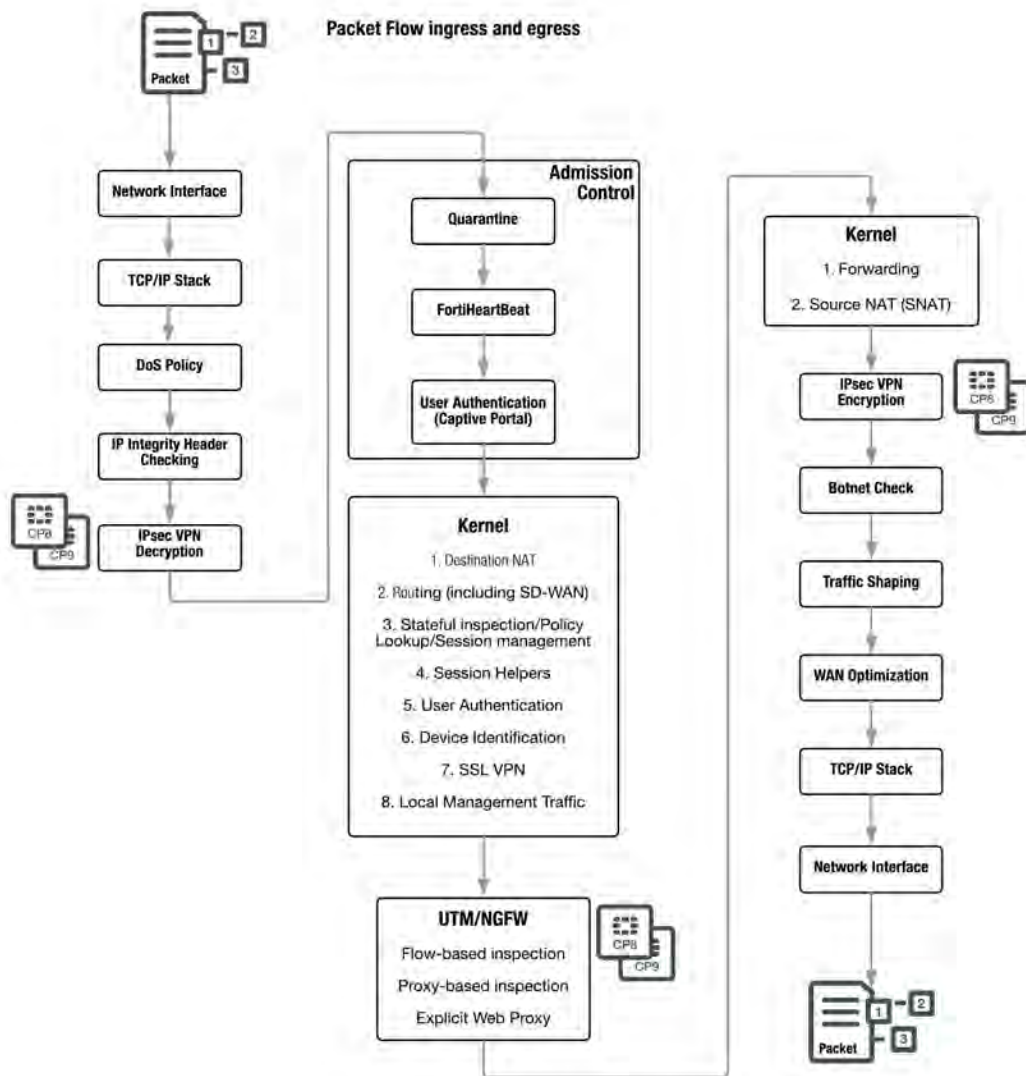

## High-level list of processes that affect packets

In general packets passing through a FortiGate can be affected by the following processes. This is a complete high-level list of all of the processes. Not all packets see all of these processes. The processes a packet encounters depends on the type of packet and on the FortiGate software and hardware configuration.

- **Ingress packet flow**
  - Network Interface
  - TCP/IP stack
  - DoS Policy
  - IP integrity header checking
  - IPsec VPN decryption
- **Admission Control**
  - Quarantine
  - FortiTelemetry
  - User Authentication
- **Kernel**
  - Destination NAT
  - Routing
  - Stateful inspection/Policy Lookup/Session management
  - Session Helpers
  - User Authentication
  - Device Identification
  - SSL VPN
  - Local Management Traffic
- **UTM/NGFW**
  - Flow-based inspection
    - NTurbo
    - IPSA
  - Proxy-based inspection
  - Explicit Web Proxy
- **Kernel**
  - Forwarding
  - Source NAT (SNAT)
- **Egress packet flow**
  - IPsec VPN Encryption
  - Botnet check
  - Traffic shaping
  - WAN Optimization
  - TCP/IP stack
  - Network Interface

## Packet flow ingress and egress: FortiGates without network processor offloading

This section describes the steps a packet goes through as it enters, passes through and exits from a FortiGate. This scenario shows all of the steps a packet goes through if a FortiGate does not contain network processors (such as the NP6).

### Ingress

All packets accepted by a FortiGate pass through a network interface and are processed by the TCP/IP stack. Then if **DoS policies** have been configured the packet must pass through these as well as automatic **IP integrity header checking**.

DoS scans are handled very early in the life of the packet to determine whether the traffic is valid or is part of a DoS attack. The DoS module inspects all traffic flows but only tracks packets that can be used for DoS attacks (for example, TCP SYN packets), to ensure they are within the permitted parameters. Suspected DoS attacks are blocked, other packets are allowed.

IP integrity header checking reads the packet headers to verify if the packet is a valid TCP, UDP, ICMP, SCTP or GRE packet. The only verification that is done at this step to ensure that the protocol header is the correct length. If it is, the packet is allowed to carry on to the next step. If not, the packet is dropped.

Incoming **IPsec packets** that match configured IPsec tunnels on the FortiGate are decrypted after header checking is done.

If the packet is an IPsec packet, the IPsec engine attempts to decrypt it. If the IPsec engine can apply the correct encryption keys and decrypt the packet, the unencrypted packet is sent to the next step. Non-IPsec traffic and IPsec traffic that cannot be decrypted passes on to the next step without being affected. IPsec VPN decryption is offloaded to and accelerated by CP8 or CP9 processors.

## Admission control

Admission control checks to make sure the packet is not from a source or headed to a destination on the quarantine list. If configured admission control then imposes FortiTelemetry protection that requires a device to have FortiClient installed before allowing packets from it. Admission control can also impose captive portal authentication on ingress traffic.

## Kernel

Once a packet makes it through all of the ingress steps, the FortiOS kernel performs the following checks to determine what happens to the packet next.

### Destination NAT

Destination NAT checks the NAT table and determines if the destination IP address for incoming traffic must be changed using DNAT. DNAT is typically applied to traffic from the internet that is going to be directed to a server on a network behind the FortiGate. DNAT means the actual address of the internal network is hidden from the internet. This step determines whether a route to the destination address actually exists. DNAT must take place before routing so that the FortiGate can route packets to the correct destination.

### Routing (including SD-WAN)

Routing uses the routing table to determine the interface to be used by the packet as it leaves the FortiGate. Routing also distinguishes between local traffic and forwarded traffic. Firewall policies are matched with packets depending on the source and destination interface used by the packet. The source interface is known when the packet is received and the destination interface is determined by routing.

SD-WAN is a special application of routing that provides route selection, load balancing, and failover among two or more routes.

### Stateful inspection/policy lookup/session management

Stateful inspection looks at the first packet of a session and looks in the policy table to make a security decision about the entire session. Stateful inspection looks at packet TCP SYN and FIN flags to identify the start and end of a session, the source/destination IP, source/destination port and protocol. Other checks are also performed on

the packet payload and sequence numbers to verify it as a valid session and that the data is not corrupted or poorly formed.

When the first packet of a session is matched in the policy table, stateful inspection adds information about the session to its session table. So when subsequent packets are received for the same session, stateful inspection can determine how to handle them by looking them up in the session table (which is more efficient than looking them up in the policy table).

Stateful inspection makes the decision to drop or allow a session and apply security features to it based on what is found in the first packet of the session. Then all subsequent packets in the same session are processed in the same way.

When the final packet in the session is processed, the session is removed from the session table. Stateful inspection also has a session idle timeout that removes sessions from the session table that have been idle for the length of the timeout.

See the Stateful Firewall Wikipedia article ([https://en.wikipedia.org/wiki/Stateful\\_firewall](https://en.wikipedia.org/wiki/Stateful_firewall)) for an excellent description of stateful inspection.

## Session helpers

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall. FortiOS includes the following session helpers:

- PPTP
- H323
- RAS
- TNS
- TFTP
- RTSP
- FTP
- MMS
- PMAP
- SIP
- DNS-UDP
- RSH
- DCERPC
- MGCP

## User authentication

User authentication added to security policies is handled by the stateful inspection, which is why Firewall authentication is based on IP address. Authentication takes place after policy lookup selects a policy that includes authentication.

## Device identification

Device identification is applied if required by the matching policy.

## SSL VPN

Local SSL VPN traffic is treated like special management traffic as determined by the SSL VPN destination port. Packets are decrypted and are routed to an SSL VPN interface. Policy lookup is then used to control how packets

are forwarded to their destination outside the FortiGate. SSL encryption and decryption is offloaded to and accelerated by CP8 or CP9 processors.

### Local management traffic

Local management traffic terminates at a FortiGate interface. This can be any FortiGate interface including dedicated management interfaces. In multiple VDOM mode local management traffic terminates at the management interface. In transparent mode, local management traffic terminates at the management IP address.

Local management traffic includes administrative access, some routing protocol communication, central management from FortiManager, communication with the FortiGuard network and so on. Management traffic is allowed or blocked according to the Local In Policy list which lists all management protocols and their access control settings. You configure local management access indirectly by configuring administrative access and so on.

Management traffic is processed by applications such as the web server which displays the FortiOS GUI, the SSH server for the CLI or the FortiGuard server to handle local FortiGuard database updates or FortiGuard Web Filtering URL lookups.

Local management traffic is not involved in subsequent stateful inspection steps.

SSL VPN traffic terminates at a FortiGate interface similar to local management traffic. However, SSL VPN traffic uses a different destination port number than administrative HTTPS traffic and can thus be detected and handled differently.

## UTM/NGFW

If the policy matching the packet includes security profiles, then the packet is subject to Unified Threat Management (UTM)/Next Generation Firewall (NGFW) processing. UTM/NGFW processing depends on the inspection mode of the FortiGate: Flow-based (single pass architecture) or proxy-based. Proxy-based processing can include Explicit web proxy traffic. Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors.

Single pass flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

Proxy-based UTM/NGFW inspection can apply both flow-based and proxy-based inspection. Packets initially encounter the IPS engine, which can apply single-pass flow-based IPS and Application Control (as configured). The packets are then sent to the proxy for proxy-based inspection. Proxy-based inspection can apply VoIP inspection, DLP, AntiSpam, Web Filtering, Antivirus, and ICAP.

Explicit web proxy inspection is similar to proxy based inspection.

## Content processors (CP8 and CP9)

Most FortiGate models contain Security Processing Unit (SPU) Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 and CP9 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

## CP9 capabilities

The CP9 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration with over 10Gbps throughput
  - IPS pre-scan
  - IPS signature correlation
  - Full match processors
- High performance VPN bulk data engine
  - IPsec and SSL/TLS protocol processor
  - DES/3DES/AES128/192/256 in accordance with FIPS46-3/FIPS81/FIPS197
  - MD5/SHA-1/SHA256/384/512-96/128/192/256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
  - ESN mode
  - GCM support for NSA "Suite B" (RFC6379/RFC6460) including GCM-128/256; GMAC-128/256
- Key Exchange Processor that supports high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primary checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - True Random Number generator
  - Elliptic Curve support for NSA "Suite B"
  - Sub public key engine (PKCE) to support up to 4096 bit operation directly (4k for DH and 8k for RSA with CRT)
- DLP fingerprint support
  - TTTD (Two-Thresholds-Two-Divisors) content chunking
  - Two thresholds and two divisors are configurable

## CP8 capabilities

The CP8 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration
- High performance VPN bulk data engine
  - IPsec and SSL/TLS protocol processor
  - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
  - ARC4 in compliance with RC4
  - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primarily checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - Random Number generator compliance with ANSI X9.31
  - Sub public key engine (PKCE) to support up to 4096 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)

- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

## Kernel

Traffic is now in the process of exiting the FortiGate. The kernel uses the routing table to forward the packet out the correct exit interface.

The kernel also checks the NAT table and determines if the source IP address for outgoing traffic must be changed using SNAT. SNAT is typically applied to traffic from an internal network heading out to the internet. SNAT means the actual address of the internal network is hidden from the internet.

## Egress

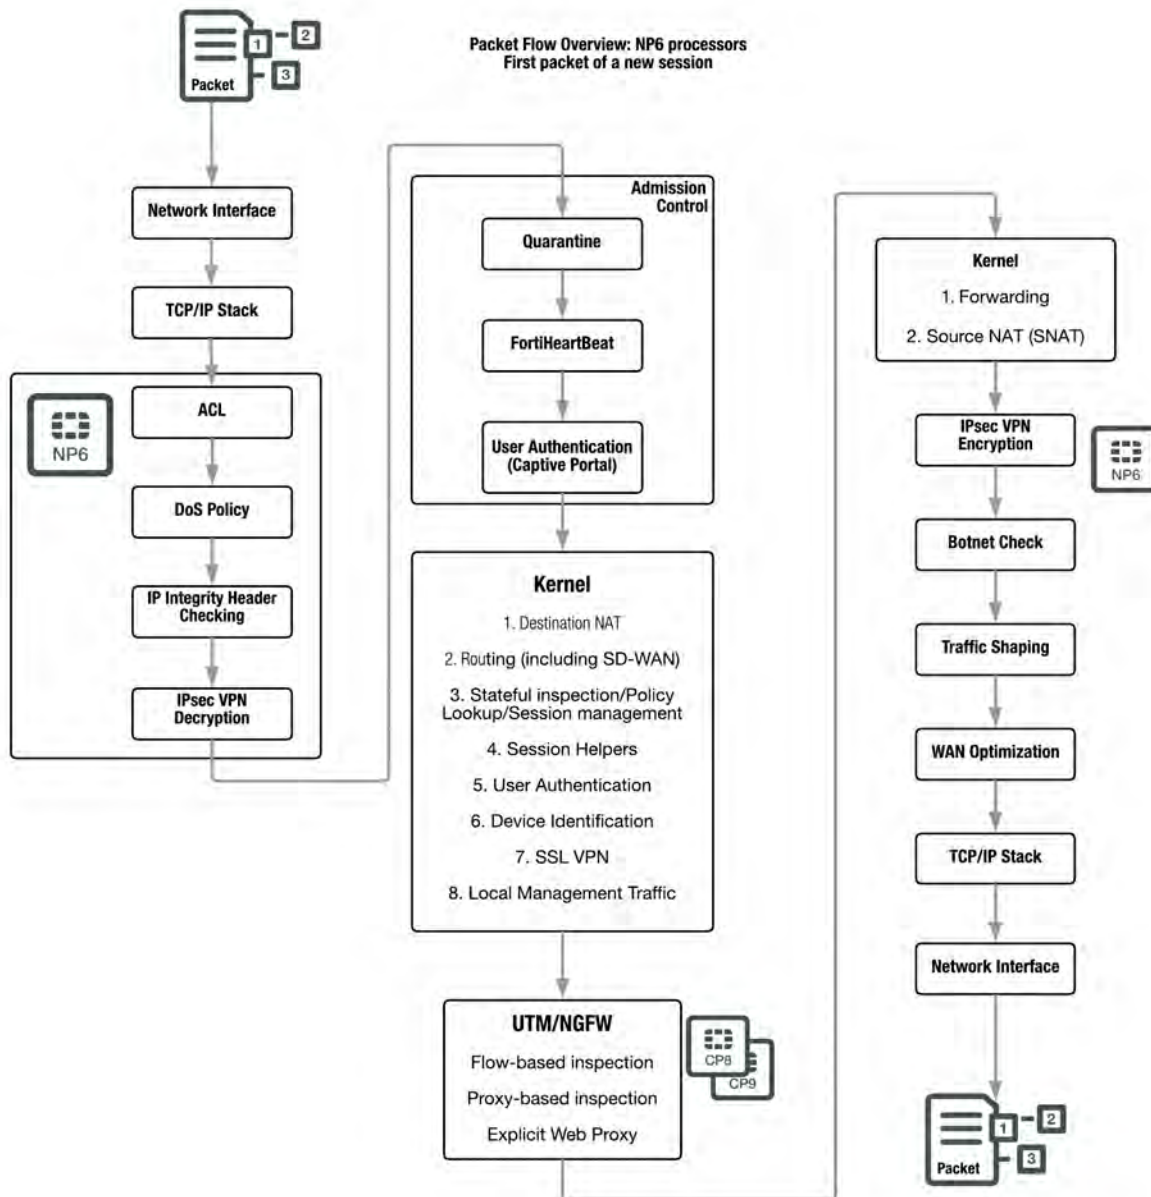

Before exiting the FortiGate, outgoing packets that are entering an IPsec VPN tunnel are encrypted and encapsulated. IPsec VPN encryption is offloaded to and accelerated by CP8 or CP9 processors. Packets are then subject to botnet checking to make sure they are not destined for known botnet addresses.

Traffic shaping is then imposed, if configured, followed by WAN Optimization. The packet is then processed by the TCP/IP stack and exits out the egress interface.

## Packet flow: NP6 and NP6lite sessions

On FortiGates with NP6 or NP6lite processors, the first packet of a session determines if the session can be offloaded. As long as there is no proxy-based UTM/NGFW, if your FortiGate includes NP6 processors, most sessions can be offloaded to them.

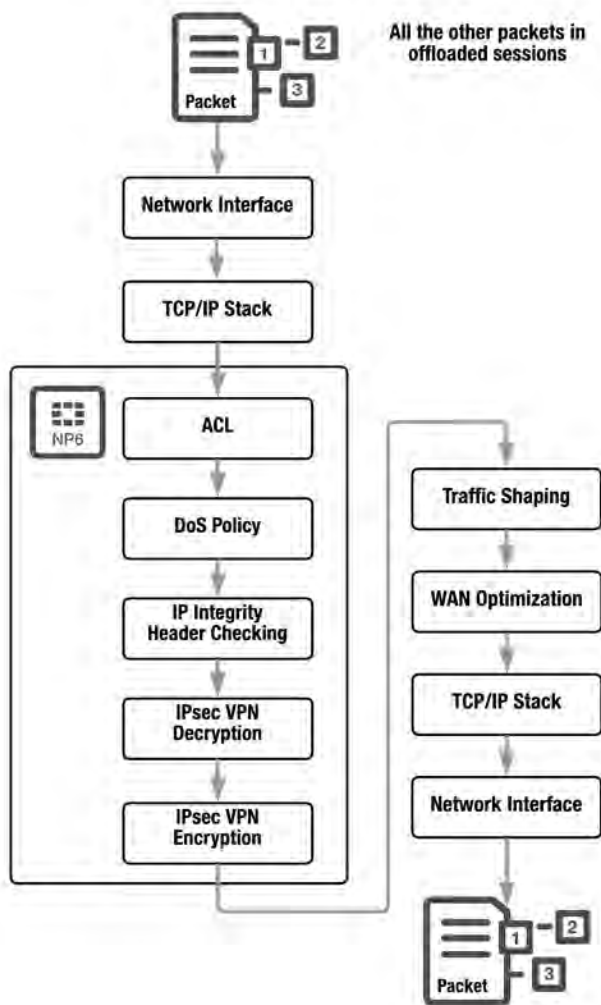

### **Access control list (ACL)**

Access Control Lists (ACLs) use NP6 offloading to drop IPv4 or IPv6 packets at the physical network interface before the packets are analyzed by the CPU. The ACL feature is available only on FortiGates with NP6-accelerated interfaces. ACL checking is one of the first things that happens to the packet and checking is done by the NP6 processor. The result is very efficient protection that does not use CPU or memory resources.

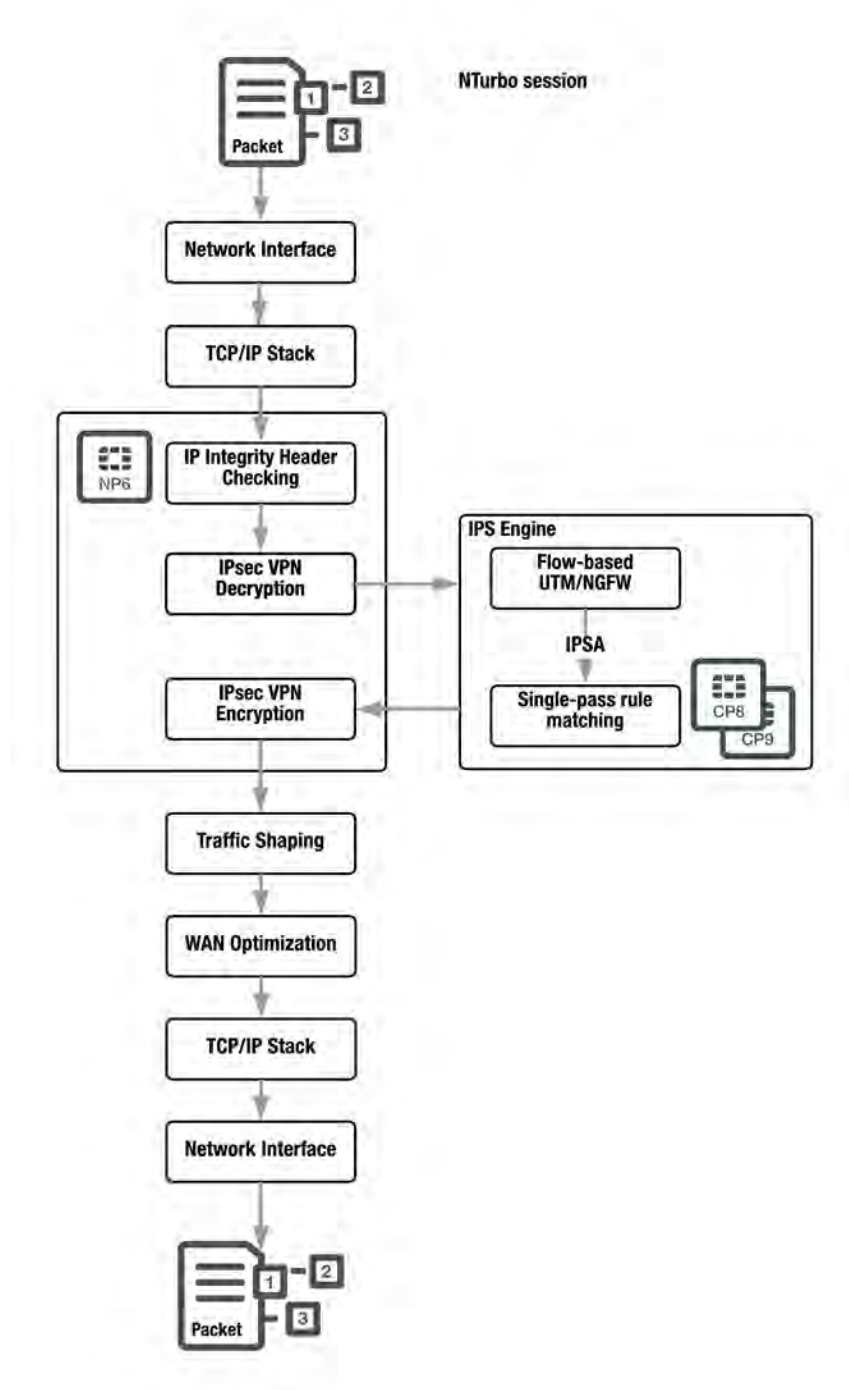

## Packet flow: NP6 and NP6lite offloaded session

After the first packet, subsequent packets in an offloaded session skip routing, UTM/NGFW, and kernel processors and are just forwarded out the egress interface by the NP6 processor. As well, security measures such as DoS policies, ACL, and so on are accelerated by the NP6 processor.

## Packet flow: NTurbo

If your FortiGate supports NTurbo, many flow-based UTM/NGFW sessions can be offloaded to NP6 processors.

After the first packet, subsequent packets in an offloaded flow-based UTM/NGFW session skip routing, and kernel processors. Flow-based UTM/NGFW operations are still handled by the CPU with IPSA offloading pattern matching to CP8 or CP9 processors.

If a security threat is found the session is dropped. Otherwise, packets that are not blocked by UTM/NGFW are forwarded out of the egress interfaces by the NP6 processor.

NTurbo is not compatible with DoS policies, session helpers, or and most types of tunneling. If any of these features are present, flow-based UTM/NGFW sessions are not offloaded by NTurbo.

## UTM/NGFW packet flow: flow-based inspection

Flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass architecture that involves Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Web Filtering**, **DLP**, and **AntiVirus**. Flow-based inspection is all done by the IPS engine and as you would expect, no proxying is involved.

Flow-based DLP is supported but not recommended. Flow-based DLP is not available from the GUI, but can be configured from the CLI.

---

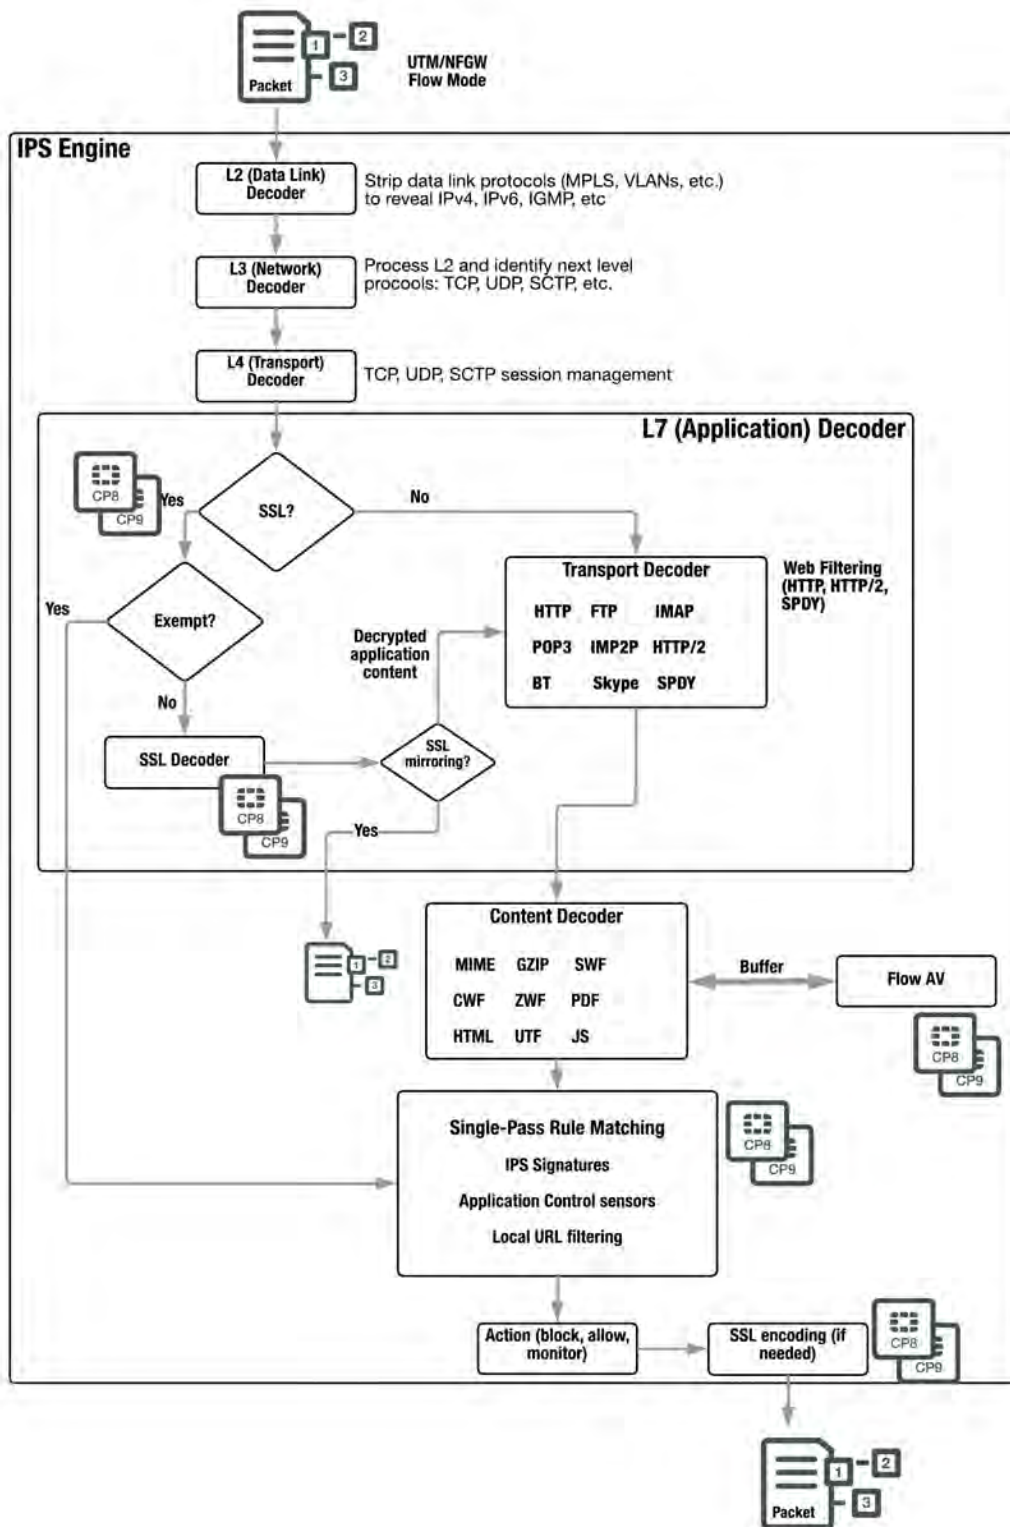

Before flow-based inspection can be applied the IPS engine uses a series of decoders to determine the appropriate security modules to be applied depending on the protocol of the packet and on policy settings. In addition, if SSL inspection is configured, the IPS engine also decrypts SSL packets. SSL decryption is offloaded and accelerated by CP8 or CP9 processors.

If your configuration includes SSL mirroring, the IPS engine copies decrypted application content, wraps it inside a TCP packet (with IP and ethernet headers), and sends it to the configured mirror interface. The TCP connection tuple is carried over from the original SSL connection. For the Ethernet frame, destination address is broadcast (FF:FF:FF:FF:FF:FF) and source address is all zeros.

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. IPS, Application Control, flow-based Web Filtering and flow-based DLP filtering happen together. Flow-based antivirus caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires less processing resources than proxy-based inspection and since its not a proxy, flow-based inspection does not change packets (unless a threat is found and packets are blocked). Flow-based inspection cannot apply as many features as proxy inspection (for example, flow-based inspection does not support client comforting and some aspects of replacement messages).

IPS and Application Control are only applied using flow-based inspection. Web Filtering, DLP and Antivirus can also be applied using proxy-based inspection.

## UTM/NGFW packet flow: proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection then a mixture of flow-based and proxy-based inspection occurs. Packets initially encounter the IPS engine, which uses the same steps described in [UTM/NGFW packet flow: flow-based inspection on page 2704](#) to apply single-pass IPS and Application Control if configured in the firewall policy accepting the traffic.

The packets are then sent to the FortiOS UTM/NGFW proxy for proxy-based inspection. The proxy first determines if the traffic is SSL traffic that should be decrypted for SSL inspection. SSL traffic to be inspected is decrypted by the proxy. SSL decryption is offloaded to and accelerated by CP8 or CP9 processors.

If your configuration includes SSL mirroring, the IPS engine copies decrypted application content, wraps it inside a TCP packet (with IP and ethernet headers), and sends it to the configured mirror interface. The TCP connection tuple is carried over from the original SSL connection. For the Ethernet frame, destination address is broadcast (FF:FF:FF:FF:FF:FF) and source address is all zeros.

Proxy-based inspection extracts and caches content, such as files and web pages, from content sessions and inspects the cached content for threats. Content inspection happens in the following order: **VoIP inspection, DLP, Ant-Spam, Web Filtering, AntiVirus, and ICAP**.

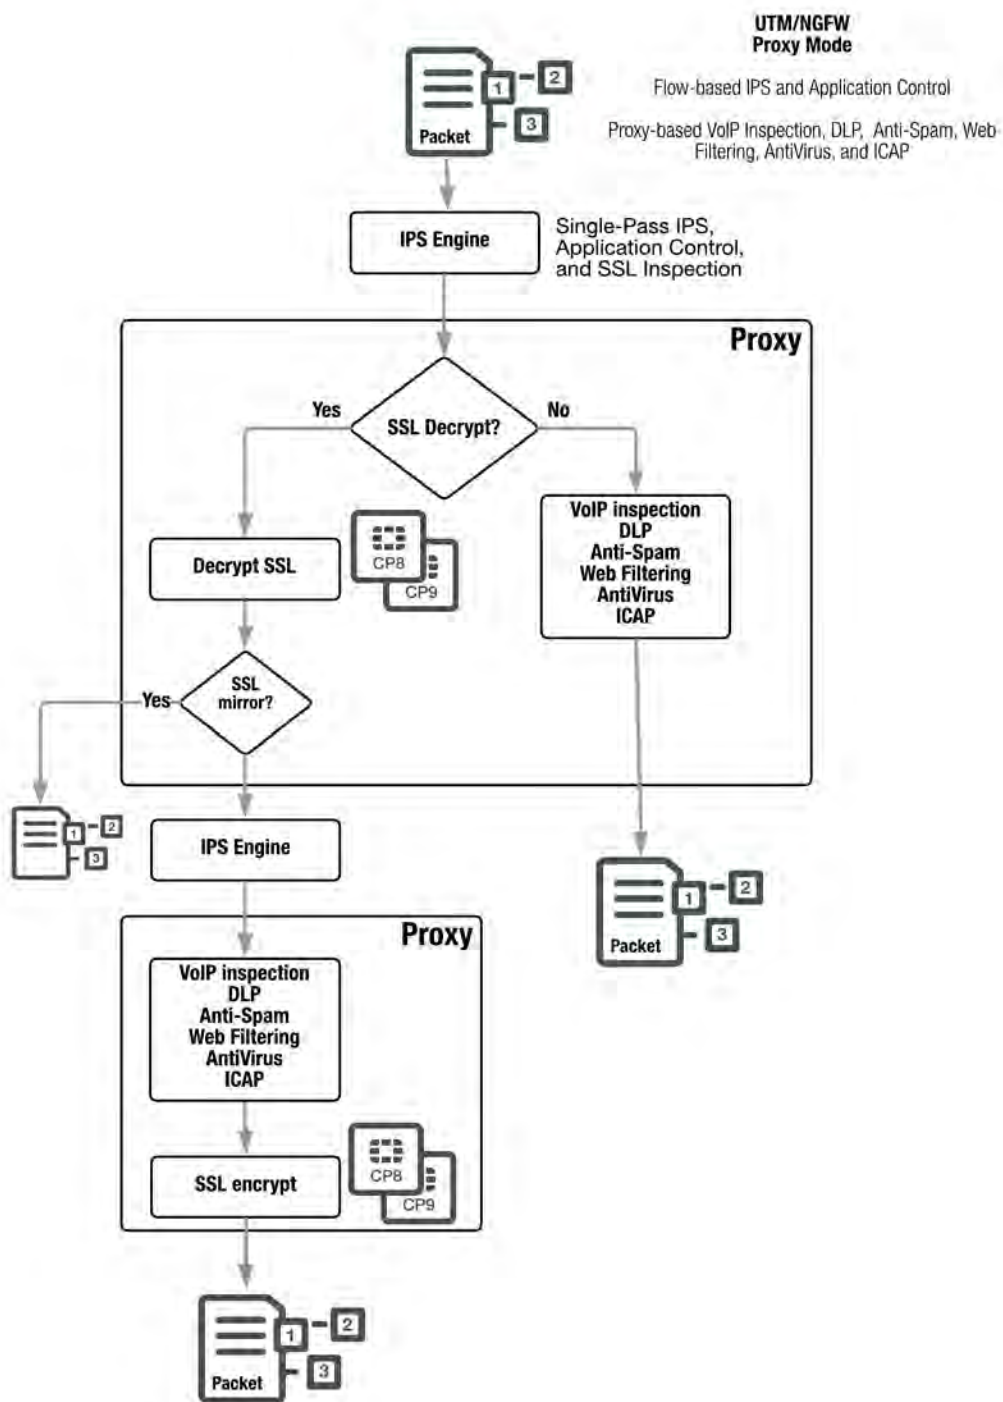

If no threat is found the proxy relays the content to its destination. If a threat is found the proxy can block the threat and replace it with a replacement message.

Decrypted SSL traffic is sent to the IPS engine (where IPS and Application Control can be applied) before re-entering the proxy where actual proxy-based inspection is applied to the decrypted SSL traffic. Once decrypted SSL traffic has been inspected it is re-encrypted and forwarded to its destination. SSL encryption is offloaded to and accelerated by CP8 or CP9 processors. If a threat is found the proxy can block the threat and replace it with a replacement message.

The proxy can also block VoIP traffic that contains threats. VoIP inspection can also look inside VoIP packets and extract port and address information and open pinholes in the firewall to allow VoIP traffic through.

ICAP intercepts HTTP and HTTPS traffic and forwards it to an ICAP server. The FortiGate is the surrogate, or “middle-man”, and carries the ICAP responses from the ICAP server to the ICAP client; the ICAP client then responds back, and the FortiGate determines the action that should be taken with these ICAP responses and requests.

## UTM/NGFW packet flow: explicit web proxy

If the explicit web proxy is enabled on a FortiGate or VDOM, a mixture of flow-based and proxy-based inspection occurs. One or more interfaces configured to listen for web browser sessions on the configured explicit web proxy port (by default 8080) accept all HTTP and HTTPS sessions on the explicit proxy port that match an explicit web proxy policy.

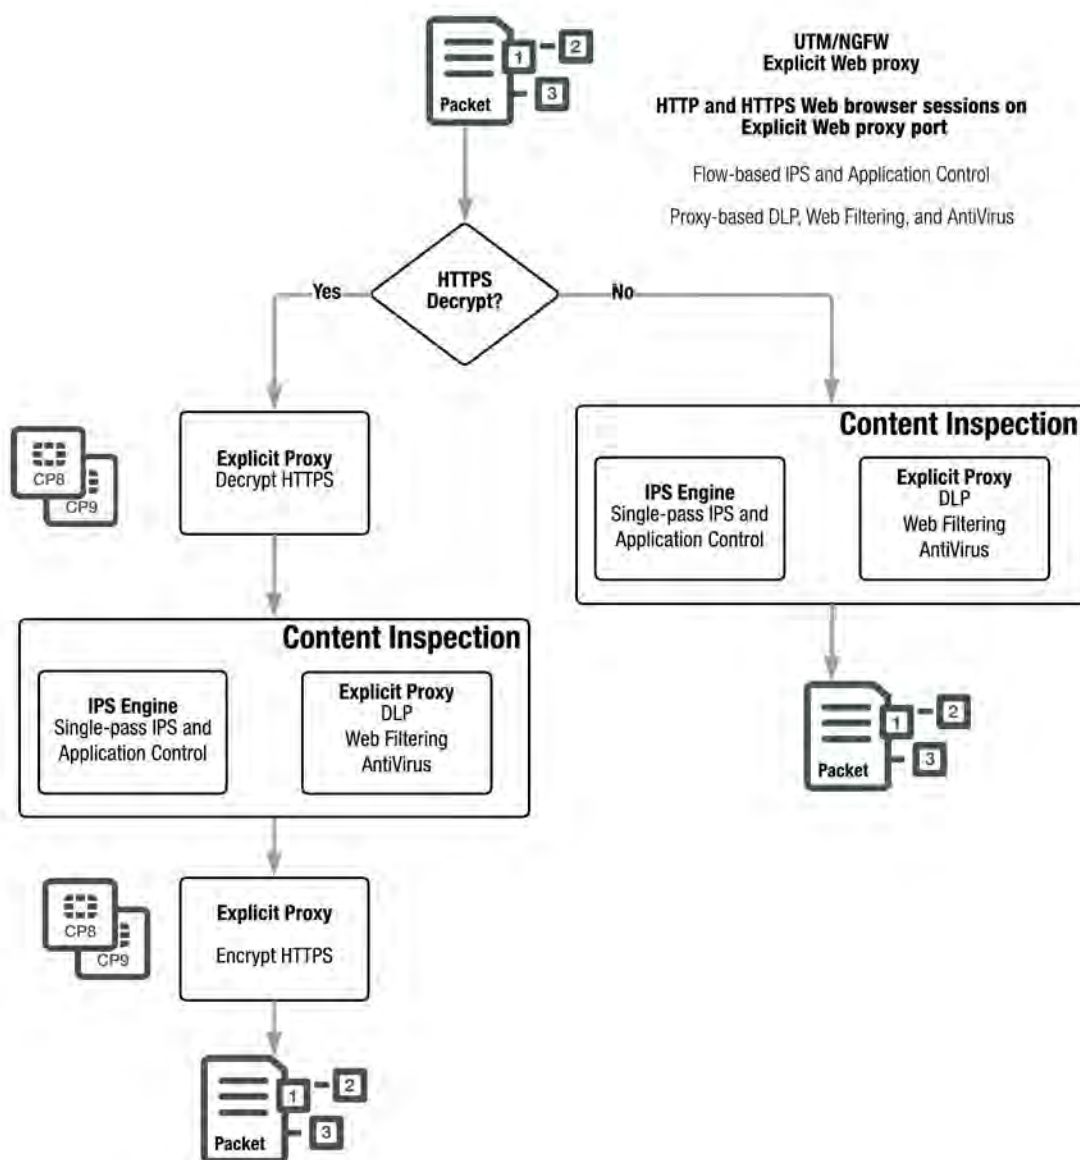

Plain text explicit web proxy HTTP traffic passes in parallel to both the IPS engine and the explicit web proxy for content scanning. The IPS engine applies IPS and application control content scanning. The explicit web proxy applies DLP, web filtering, and AntiVirus content scanning.

If the IPS engine and the explicit proxy do not detect any security threats, FortiOS relays the content to a destination interface. If the IPS engine or the explicit proxy detect a threat, FortiOS can block the threat and replace it with a replacement message.

Encrypted explicit web proxy HTTPS traffic passes to the explicit web proxy for decryption. Decrypted traffic once again passes in parallel to the IPS engine and the explicit web proxy for content scanning.

If the IPS engine and the explicit proxy do not detect any security threats, the explicit proxy re-encrypts the traffic and FortiOS relays the content to its destination. If the IPS engine or the explicit proxy detect a threat, FortiOS can block the threat and replace it with a replacement message. The explicit proxy offloads HTTPS decryption and encryption to CP8 or CP9 processors.

FortiOS uses routing to route explicit web proxy sessions through the FortiGate to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. A FortiGate operating in transparent mode changes the source address to the transparent mode management IP address. You can also configure the explicit web proxy to keep the original client IP address.

## Comparison of inspection types

The tables in this section show how different security functions map to different inspection types.

### Mapping security functions to inspection types

The table below lists FortiOS security functions and shows whether they are applied by the kernel, flow-based inspection or proxy-based inspection.

#### FortiOS security functions and inspection types

| Security Function   | Kernel<br>(Stateful inspection) | Flow-based inspection | Proxy-based inspection |
|---------------------|---------------------------------|-----------------------|------------------------|
| Firewall            | yes                             |                       |                        |
| IPsec VPN           | yes                             |                       |                        |
| Traffic Shaping     | yes                             |                       |                        |
| User Authentication | yes                             |                       |                        |
| Management Traffic  | yes                             |                       |                        |
| SSL VPN             | yes                             |                       |                        |
| IPS                 |                                 | yes                   |                        |
| Antivirus           |                                 | yes                   | yes                    |
| Application Control |                                 | yes                   |                        |
| Web filtering       |                                 | yes                   | yes                    |
| DLP                 |                                 | yes                   | yes                    |
| Email Filtering     |                                 |                       | yes                    |
| VoIP inspection     |                                 |                       | yes                    |
| ICAP                |                                 |                       | yes                    |

### More information about inspection methods

The three inspection methods each have their own strengths and weaknesses. The following table looks at all three methods side-by-side.

**Inspection methods comparison**

| Feature                     | Stateful     | Flow                                                                                                  | Proxy                                                            |
|-----------------------------|--------------|-------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| Inspection unit per session | first packet | selected packets, single pass architecture, simultaneous application of configured inspection methods | complete content, configured inspection methods applied in order |
| Memory, CPU required        | low          | medium                                                                                                | high                                                             |
| Level of threat protection  | good         | better                                                                                                | best                                                             |
| Authentication              | yes          |                                                                                                       |                                                                  |
| IPsec and SSL VPN           | yes          |                                                                                                       |                                                                  |
| Antivirus protection        |              | yes                                                                                                   | yes                                                              |
| Web Filtering               |              | yes                                                                                                   | yes                                                              |
| Data Leak Protection (DLP)  |              | yes                                                                                                   | yes                                                              |
| Application control         |              | yes                                                                                                   |                                                                  |
| IPS                         |              | yes                                                                                                   |                                                                  |
| Delay in traffic            | minor        | no                                                                                                    | small                                                            |
| Reconstruct entire content  |              | no                                                                                                    | yes                                                              |

# Chapter 23 - Sandbox Inspection

## Sandbox inspection

This guide explains how to set up sandbox inspection using FortiSandbox with a FortiGate. It contains the following sections:

- [What's New in FortiOS 5.6.1](#): Highlights new features added.
- [An Overview of Sandbox Inspection](#): General information about how sandbox inspection works.
- [Using FortiSandbox with a FortiGate](#): How to set up sandbox inspection on a FortiGate.
- [Sandbox Integration](#): Integrating sandbox inspection with FortiGate, FortiSandbox, and FortiClient.
- [Sandbox Inspection FAQ](#): Frequently asked questions to help troubleshoot sandbox inspection.

## What's new in FortiOS 5.6

The following section describes new Sandbox Integration features added to FortiOS 5.6.1.

### FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

#### **New file extension lists for determining which file types to send to FortiSandbox (379326)**

This feature introduces two new file extension lists:

- File extensions to submit to FortiSandbox even though the AV engine says they are unsupported.
- File extensions to exclude from submitting to FortiSandbox even though the AV engine says they are supported.

These lists are configured on the FortiSandbox, not the FortiGate, and are dynamically loaded on the FortiGate via quarantine.

These lists are only file extensions and not file types detected by the AV engine using magic bytes. Pattern matching is done on the extension of the filename only.

---

#### **Syntax**

```
diag sys scanunit reload-fsa-ext
```

#### **FortiSandbox integration with AntiVirus in quick mode (436380)**

FortiSandbox options in an AntiVirus Security Profile in quick scanning mode can now be enabled with CLI commands.

**CLI syntax**

```
config antivirus profile
edit default
 set ftgd-analytics disable/everything
 set analytics-max-upload 10
 set analytics-wl-filetype 0
 set analytics-bl-filetype 0
 set analytics-db enable/disable
 set scan-mode quick
end
```

## An Overview of Sandbox Inspection

This section contains information about how Fortinet sandbox inspection works.

- [What is Sandbox Inspection?](#)
- [FortiSandbox Appliance vs FortiSandbox Cloud](#)
- [Sending Files for Sandbox Inspection](#)

### What is Sandbox Inspection?

Sandbox inspection is a network process that allows files to be sent to a separate device, such as FortiSandbox, to be inspected without risking network security. This allows the detection of threats which may bypass other security measures, including zero-day threats.

You can configure your FortiGate device to send suspicious files to FortiSandbox for inspection and analysis. The FortiGate queries scan results and retrieves scan details. The FortiGate can also download malware packages as a complimentary AV signature database to block future appearances of the same malware and download URL packages as complimentary web filtering black list.

When a FortiGate sends files for sandbox inspection, the FortiSandbox uses virtual machines (VMs) running different operating systems to test the file and to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to the FortiGuard AntiVirus signature database.

When a FortiGate learns from FortiSandbox that a terminal is infected, the administrator can push instruction for self-quarantine on a registered FortiClient host.

FortiSandbox can process multiple files simultaneously since the FortiSandbox has a VM pool. The time to process a file depends on hardware and the number of sandbox VMs used to scan the file. It can take 60 seconds to five minutes to process a file.

### FortiSandbox Appliance vs FortiSandbox Cloud

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiSandbox Cloud).

To select the settings for **Sandbox Inspection**, such as the FortiSandbox type, server, and notifier email, go to **Security Fabric > Settings**.

The table below highlights the supported features of both types of FortiSandbox:

| Feature                                         | FortiSandbox Appliance<br>(including VM) | FortiSandbox Cloud                      |
|-------------------------------------------------|------------------------------------------|-----------------------------------------|
| Sandbox inspection for FortiGate                | Yes (FortiOS 5.0.4+)                     | Yes (FortiOS 5.2.3+)                    |
| Sandbox inspection for FortiMail                | Yes (FortiMail OS 5.1+)                  | Yes (FortiMail OS 5.3+)                 |
| Sandbox inspection for FortiWeb                 | Yes (FortiWeb OS 5.4+)                   | Yes (FortiWeb OS 5.5.3+)                |
| Sandbox inspection for FortiClient              | Yes (FortiClient 5.4+ for Windows only)  | No                                      |
| Sandbox inspection for network share            | Yes                                      | No                                      |
| Sandbox inspection for ICAP client              | Yes                                      | No                                      |
| Manual File upload for analysis                 | Yes                                      | Yes                                     |
| Sniffer mode                                    | Yes                                      | Yes                                     |
| File Status Feedback and Report                 | Yes                                      | Yes                                     |
| Dynamic Threat Database updates for FortiGate   | Yes (FortiOS 5.4+)                       | Yes (FortiOS 5.4+)                      |
| Dynamic Threat Database updates for FortiClient | Yes (FortiClient 5.4 for Windows only)   | Yes (FortiClient 5.6+ for Windows only) |

Note that FortiMail keeps its own Dynamic Threat Database. For more information, see the [FortiSandbox documentation](#).

## Sending Files for Sandbox Inspection

Sending files to the FortiSandbox appliance or to FortiSandbox Cloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is downloaded by the FortiGate every two minutes for live detection.

Enable **Sandbox Inspection** by going to **Security Fabric > Settings**. You can also configure the FortiSandbox type, server, and notifier email.

To see options for sending files for sandbox inspection, go to **Security Profiles > AntiVirus**. There are two options for sending files: **None** or **All Supported Files**. If **All Supported Files** is selected, users can withhold files from being submitted for inspection by type or name pattern.

To learn how to connect the FortiSandbox, go to ["Using FortiSandbox with a FortiGate" on page 2716](#)

## Using FortiSandbox with a FortiGate

This section contains information about how to use sandbox inspection with FortiSandbox and FortiGate. It includes the following sections:

- [Connecting a FortiGate to FortiSandbox](#)
- [FortiSandbox Console](#)

### Connecting a FortiGate to FortiSandbox

The procedures for connecting a FortiGate to FortiSandbox differ depending whether you are using [FortiSandbox Appliance](#) or [FortiSandbox Cloud](#).

If you are using FortiSandbox in a Fortinet Security Fabric, consult the [Fortinet Cookbook](#) site for the [Fortinet Security Fabric collection](#) of recipes.

Once the FortiGate is connected to FortiSandbox, an AntiVirus profile can be configured to send suspicious files for inspection. Sandbox integration can also be configured, for more information see "[Sandbox Integration](#)" on [page 2718](#).

#### Connecting to FortiSandbox Appliance

1. Connect the FortiSandbox Appliance to your FortiGate so that port 1 and port 3 on the FortiSandbox are on different subnets.

FortiSandbox port 3 is used for outgoing communication triggered by the execution of the files under analysis. While the FortiSandbox can accept files through any port, it is recommended to connect port 3 to a dedicated interface on your FortiGate to protect the rest of the network from threats currently being investigated by the FortiSandbox. Note too that port 1 can be used to accept files but is generally reserved for managing the FortiSandbox.

---

2. FortiSandbox port 3 must be able to connect to the Internet. On the FortiGate, go to **Policy & Objects > IPv4 Policy** and create a policy allowing connections from the FortiSandbox to the Internet (using the isolated interface on the FortiGate mentioned above). On FortiSandbox, network settings for port3 can be configured by going to **Scan Policy > General**.
3. On the FortiSandbox, go to **Network > System Routing** and add static routes for port 1.
4. On the FortiSandbox, go to **Dashboard** and locate the **System Information** widget. Now that the FortiSandbox has Internet access, it can activate its VM licenses. Wait until a green arrow shows up beside **Windows VM** before continuing to the next step.
5. On the FortiGate, go to **Security Fabric > Settings**. Select **Enable Sandbox Inspection** and select **FortiSandbox Appliance**. Set the **IP Address** and enter a **Notifier Email**. If you select **Test Connectivity**, the **Status** shows as **Service is not configured** because the FortiGate has not been authorized to connect to the FortiSandbox.
6. On the FortiSandbox, go to **Scan Input > Device**. **Edit** the entry for the FortiGate. Under **Permissions & Policy > Authorized**, select the checkbox and click **OK** to authorize the FortiGate.

- On the FortiGate, go to **Security Fabric > Settings** and select **Test Connectivity** for the FortiSandbox. The **Status** now shows that **Service is online**.

### Connecting to FortiSandbox Cloud

Before you can connect a FortiGate to FortiSandbox Cloud, you need an active FortiCloud account.

Once you have created a FortiCloud account, sandbox inspection should be enabled by default. To verify this, go to **Security Fabric > Settings**, enable **Sandbox Inspection**, and set to **FortiSandbox Cloud**.

To see the results from FortiSandbox Cloud in the FortiGate logs, go to **Log & Report > Log Settings** and enable **Send Logs to FortiCloud** and set **GUI Preferences** is to display logs from FortiCloud.

### FortiSandbox Console

The FortiSandbox console is available at **FortiView > FortiSandbox**. The console displays all samples submitted for inspection. Information on the console can be filtered by checksum, file name, result, source, status, and user name.

| Add Filter                    |                           | Files  | Source              | 5 minutes | 1 hour | 24 hours |
|-------------------------------|---------------------------|--------|---------------------|-----------|--------|----------|
| Source                        | File Name                 | Status | Submitted           |           |        |          |
| vickimartin (192.168.200.110) | Breakpoints.js            | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Corp_Reverb.css           | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | FortiOS%205.2%20CLI_sx.js | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Language.js               | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | MadCapAll.js              | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Slideshow.css             | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Toc.js                    | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Toc_Chunk6.js             | Clean  | 10/02/2015 09:40:00 |           |        |          |
| vickimartin (192.168.200.110) | Web.css                   | Clean  | 10/02/2015 09:40:00 |           |        |          |

If you right-click on an entry, you can choose to **Drill Down to Details**, **Quarantine Source Address**, or **Quarantine FortiClient Device**.

Information about the FortiSandbox database and sandboxing statistics are available at **Security Fabric > Settings** once sandbox inspection is enabled. The **Advanced Threat Protection** dashboard widget shows you the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox.

## Sandbox Integration

Sandbox integration adds another level to sandbox inspection, allowing you to set up automatic actions to protect your network from files FortiSandbox determines are malicious. These actions include: receiving AntiVirus signature updates from FortiSandbox, adding the originating URL of any malicious file to a blocked URL list, and extending sandbox scanning to FortiClient devices.

This section contains the following topics:

- [Overview](#)
- [Example Configuration](#)

### Overview

FortiSandbox integration involves three different FortiGate security profiles: [AntiVirus](#), [Web Filtering](#), and [FortiClient Profiles](#).

A FortiGate can retrieve scan results and details from FortiSandbox, and also receive antivirus and web filtering signatures to supplement the current signature database. When FortiGate learns from FortiSandbox that an endpoint is infected, the administrator can push instruction for self-quarantine on a registered FortiClient host.

When integrated with a FortiGate unit, the following protocols are supported by FortiSandbox: HTTP, HTTPS, FTP, FTPS, POP3, POP3S, IMAP, IMAPS, SMTPS, MAPI, MAPIS, SMB, and supported IM protocols.

### AntiVirus

When FortiSandbox discovers a malicious file, it can create an AntiVirus signature for that file and add that signature to both the local FortiGate malware database and the FortiGuard AntiVirus signature database. Through FortiSandbox integration, this signature can be sent to a FortiGate to block the file from re-entering the network and to prevent the future retransmission of that file to FortiSandbox.

Use of the FortiSandbox AntiVirus database is enabled in an AntiVirus profile, found at **Security Profiles > AntiVirus**. It can also be configured using the following CLI commands:

```
config antivirus profile
 edit <profile>
 set analytics-db enable
 end
```

### Web Filtering

FortiSandbox integration can also be used to allow FortiSandbox to add a URL filter blocking the source of a discovered malicious file to the FortiGate's blocked URL list.

Blocking malicious URLs discovered by FortiSandbox is enabled in a Web Filter profile, found at **Security Profiles > Web Filter**. It can also be configured using the following CLI commands:

```
config webfilter profile
 edit <profile>
 config web
 set blacklist enable
 end
```

## FortiClient Profiles

Extended FortiSandbox scanning is currently only supported by FortiClient 5.4 for Windows. It can also only be used with FortiSandbox Appliance.

When extended FortiSandbox scanning is enabled for FortiClient, files downloaded by FortiClient can be sent to the FortiSandbox for inspection. Also, if a suspicious file is discovered, FortiClient can be configured to wait until sandbox inspection is complete before allowing that file to be accessed.

AntiVirus signatures can also be pushed by the FortiGate to FortiClient.

If a FortiClient device attempts to download a file that FortiSandbox discovers is malicious, the FortiSandbox notifies the FortiGate. The administrator can take action to quarantine the device. When a quarantine is in effect, FortiClient cuts off other network traffic from the device directly, preventing it from infecting or scanning the local network. When a device is under quarantine, FortiClient cannot be shutdown or uninstalled. A user is also unable to unregister from the FortiGate that quarantined them, or register to another FortiGate unit. A quarantine can only be lifted by the administrator of the FortiGate where the FortiClient device is registered.

Extending FortiSandbox scanning can be configured in the **Security** settings of a FortiClient Profile, found at **Security Profiles > FortiClient Profiles**. It can also be configured using the following CLI commands:

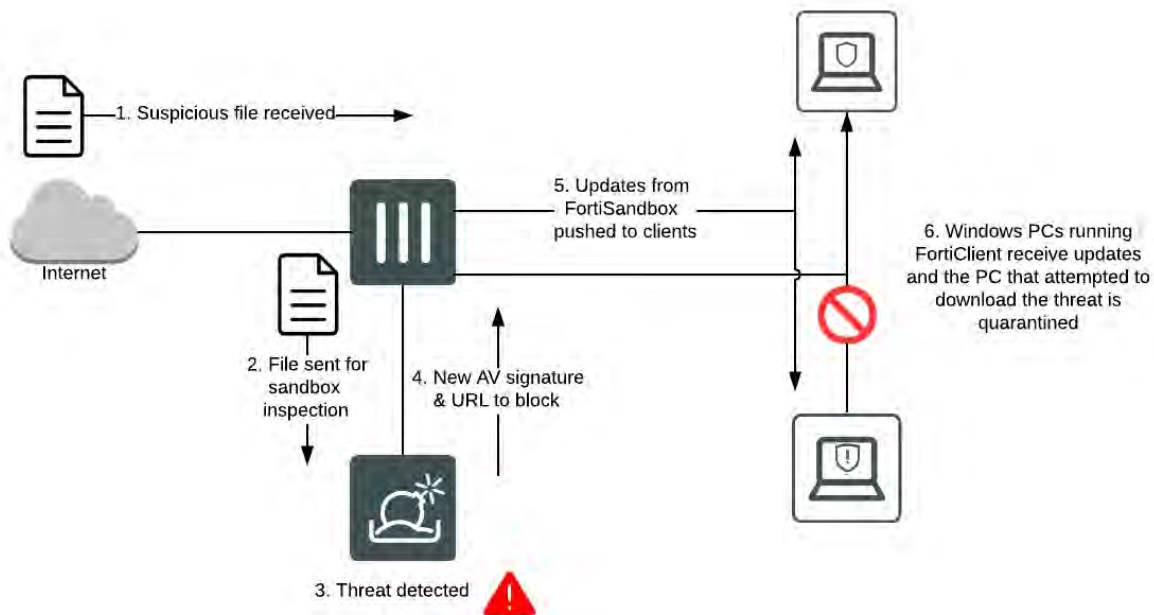

```
config endpoint-control profile
 edit <profile>
 config forticlient-winmac-settings
 set forticlient-av enable
 set av-realtime-protection enable
 set sandbox-analysis enable
 set sandbox-address <address>
 end
```

Extending FortiSandbox scanning can also be configured directly in the FortiClient **AntiVirus** settings. If you are using FortiClient version 5.6+, the **Sandbox Detection** feature can be used to send files to FortiSandbox for analysis without having to install the AntiVirus feature. See the FortiClient 5.6 Administration Guide for details.

The number of files sent from a single device to FortiSandbox can be limited by [configuring the submission limit](#) on the FortiSandbox. This allows users to prioritize which devices get the greater share of FortiSandbox resources.

## Example Configuration

The following example configuration sets up FortiSandbox integration using AntiVirus, Web Filtering, and a FortiClient profile. This configuration assumes that a connection has already been established between the FortiSandbox Appliance and the FortiGate.

1. Go to **Security Fabric > Settings** and confirm that **Sandbox Inspection** is enabled and the **FortiSandbox Appliance** is connected.
2. Go to **Security Profiles > AntiVirus** and edit the default profile. Under **Inspection Options**, select **All Supported Files** to be sent for inspection and enable **Use FortiSandbox Database**. You have the option of withholding files by name or pattern. Select **Apply**.
3. Go to **Security Profiles > Web Filter** and edit the default profile. Under **Static URL Filter**, enable **Block malicious URLs discovered by FortiSandbox**. Select **Apply**.
4. Go to **Security Profiles > FortiClient Profiles** and edit the default profile. Under **Security Posture Check**, enable **Realtime Protection**. Next, enable **Scan with FortiSandbox**. Select **Apply**.
5. Go to **Policy & Objects > IPv4 Policy** and view the policy list. If a policy has AntiVirus and Web Filtering profiles scanning applied, the profiles will be listed in the **Security Profiles** column. If scanning needs to be added to any security policy (excluding the **Implicit Deny** policy) select the **+** button in the **Security Profiles** column for that policy, then select the default **AntiVirus Profile**, the default **Web Filter Profile**, the appropriate **Proxy Options**, and select the **deep-inspection** profile for **SSL/SSH Inspection** (to ensure that encrypted traffic is inspected).
6. Select **OK**.

## Results

If your FortiGate discovers a suspicious file, it will be sent to the FortiSandbox. To view information about the files that have been sent on the FortiGate, go to **FortiView > FortiSandbox** to see a list of file names and current status.

To view results on the FortiSandbox, go to the **Dashboard** and view the **Scanning Statistics** widget. There may be a delay before results appear on the FortiSandbox.

Open FortiClient using a Windows PC on the internal network. Make sure it is registered to your FortiGate. Go to the **AntiVirus** tab and open **Settings**. You will see that the **Realtime Protection** settings match the FortiClient profile configured on the FortiGate. These settings cannot be changed using FortiClient.

If a PC running FortiClient downloads a suspicious file that the FortiSandbox determined was malicious, a quarantine would be applied automatically. While the quarantine is in effect, FortiClient cannot be shutdown on the PC. It can not be uninstalled or unregistered from the FortiGate. The quarantine can only be released from the FortiClient Monitor on the FortiGate.

## Sandbox Inspection FAQ

The following are some frequently asked questions about using sandbox inspection with FortiSandbox and FortiGate.

### **Why is the FortiSandbox Cloud option not available when sandbox inspection is enabled?**

This option is only available if you have already created a FortiCloud account.

### **Why don't results from FortiSandbox Cloud appear in the FortiGate GUI?**

Go to **Log & Report > Log Settings** and make sure **Send Logs to FortiCloud** is enabled and **GUI Preferences** is set to **Display Logs from FortiCloud**.

### **Why are the FortiSandbox Appliance VMs inactive?**

Make sure that port 3 on the FortiSandbox has an active Internet connection. This is required in order to activate the FortiSandbox VMs.

### **Why aren't files are being scanned by FortiSandbox?**

Make sure an AntiVirus profile that sends files to FortiSandbox is enabled for all policies that require sandbox inspection.

### **Is FortiSandbox supported by FortiGate when in NAT or Transparent mode?**

Yes, both NAT and Transparent mode are supported.

### **Are FortiGates behind a NAT device supported? If so how many?**

Yes, multiple FortiGates can be supported in-line with FortiSandbox. Currently, there is a limitation where the FortiSandbox will see all FortiGates only as one device so there is no way to differentiate reports but all material will be sent.

### **If the FortiGate has a dynamic IP, will the FortiSandbox automatically update the FortiGate?**

Yes. Dynamic IPs™ are supported and the FortiGate will not have to be reconfigured on the FortiSandbox each time.

# Chapter 24 - Fortinet Security Fabric

## Fortinet Security Fabric

The Fortinet Security Fabric is an end-to-end security solution that gives you control, integration, and easy management of security across your entire organization. The Security Fabric provides an intelligent architecture that interconnects discrete security solutions into an integrated whole to detect, monitor, block, and remediate attacks across the entire enterprise attack surface.

This document is a complete reference guide for the Security Fabric, including an overview of what the Security Fabric is, what devices are included in the Security Fabric and how they work together to secure your network, and how to configure and manage the Security Fabric.

## What's new in the Security Fabric

This section contains a list of new features and enhancements for the Security Fabric.

### FortiOS version 5.6.2

There are no new features for the Security Fabric in FortiOS version 5.6.2.

### FortiOS version 5.6.1

FortiOS version 5.6.1 includes the following new features and enhancements for the Security Fabric.

#### FortiTelemetry support for IPsec VPN interfaces

You can now enable FortiTelemetry on IPsec VPN interfaces, and the Security Fabric can then detect the downstream FortiGate through the IPsec VPN interface. This allows you to send FortiTelemetry communication over a Gateway-to-Gateway IPsec VPN tunnel between two remote networks.

#### Redesigned Security Fabric menu

An updated GUI menu consolidates the Security Fabric features in one location. The new Security Fabric menu includes options for Physical Topology, Logical Topology, Audit, and Settings.

#### Security Fabric settings page improvements

The Security Fabric settings page is updated to be a centralized location where you can enable connectivity to other Fortinet products. The former **Enable Security Fabric** option is replaced by a **FortiGate Telemetry** option, which is what you use to enable the Security Fabric. The former **Downstream FortiGates** field is replaced by a **Topology** field, which shows a hierarchical map view of the FortiGates that are connected to the root FortiGate.

#### Security Fabric dashboard widget improvements

The Security Fabric dashboard widget is updated to include more Fortinet products. You can hover over the FortiGate icon to see the overall status of FortiTelemetry, and hover over the other icons to see the status of various devices in the Security Fabric.

The Security Fabric Score widget shows the Security Fabric Audit score and a list of the number of checks that were not passed, ranked by severity (Critical, High, Medium, and Low). Clicking on the widget and selecting **View/apply recommendations in Security Fabric Audit**, takes you to the Security Fabric Audit page.

#### Security Fabric topology page improvements

The Physical and Logical Topology pages include the following improvements:

- Updated Security Fabric legend
- New option to minimize the Topology: You can now show or hide areas of your organization's topology using the plus and minus signs beside the device icons in the topology pages. This makes it easier for you to view your organization's entire topology, or hide some areas of the topology to focus on other areas.

- New resource information alerts: The Security Fabric topology now shows CPU Usage and Memory Usage alerts in the device information tooltip. It also displays a warning if the FortiGate is in conserve mode.

## SD-WAN support and improvements

The Security Fabric now supports SD-WAN by including SD-WAN information in the Security Fabric topology, and adds SD-WAN monitoring support.

The Security Fabric topology now includes SD-WAN information. Enhancements include greater visibility into where the data comes from and goes to, link saturation indicators, and detailed tooltip explanations.

The Security Fabric now retrieves monitoring information from all devices in the Security Fabric and displays it in the **Monitor** pages, such as the **Routing Monitor** or **Quarantine Monitor** pages, in the root FortiGate GUI. You can use the new drop-down menu in the monitor pages to select the device in the Security Fabric that you would like to see monitoring information for.

## FortiOS version 5.6

FortiOS version 5.6 includes the following new features and enhancements for the Security Fabric.

### Security Fabric dashboard widgets

New dashboard widgets for the Security Fabric allow you to see information about the status of the Security Fabric on the dashboard when you log in to the FortiGate.

### Physical and Logical FortiView improvements

The FortiView Physical and Logical Topology pages include many improvements for the Security Fabric, such as showing more devices, displaying link usage in different colors, ranking endpoints, and allowing you to search for specific devices.

### FortiClient Vulnerability Score

Endpoints in the Security Fabric topology are now ranked by their FortiClient Vulnerability Score. This score is calculated by the severity of vulnerabilities found on the endpoint.

### FortiView consolidation

Information about the Security Fabric can now be seen throughout the FortiView dashboard on the upstream FortiGate when you use the real-time view.

### Remote login to downstream FortiGates

You can now log in to downstream FortiGates from the upstream FortiGate, by right-clicking on the downstream FortiGate when viewing the Security Fabric topology using FortiView.

### Logging consolidation and improvements

The following changes have been made to improve logging for the Security Fabric:

- All FortiGates in the Security Fabric now send logs to a single FortiAnalyzer, by default. You configure the connection to the FortiAnalyzer on the root FortiGate and the settings are then pushed to all other FortiGates in the Security Fabric.

- The following information about the Security Fabric configuration is now sent to the FortiAnalyzer: topology information, interface roles, latitude and longitude information, and device asset tags.
- Monitors on the upstream FortiGate, such as the VPN Monitor, Route Monitor, and User Quarantine, can now view the information from downstream devices.
- You can now see the log statistics for each FortiGate in the Security Fabric.

### Device tree

The entire Security Fabric tree is now updated upward and each node has an updated state of the whole subtree.

## Security Fabric overview

The Fortinet Security Fabric provides a visionary approach to security that allows your organization to deliver intelligent, powerful, and seamless security. Fortinet offers security solutions for endpoints, access points, network elements, the data center, applications, cloud, and data, designed to work together as an integrated security fabric that can be integrated, analyzed, and managed to provide end-to-end protection for your network. Your organization can also add third-party products that are members of Fortinet's Fabric-Ready Partner Program to the Security Fabric.

All elements in the Security Fabric work together as a team to share policy, threat intelligence, and application flow information. This collaborative approach expands network visibility and provides fast threat detection in real time and the ability to initiate and synchronize a coordinated response, no matter which part of the network is being compromised. The Security Fabric allows your network to automatically see and dynamically isolate affected devices, partition network segments, update rules, push out new policies, and remove malware.

The Security Fabric is designed to cover the entire attack surface and provide you with complete visibility into your network. It allows you to collect, share, and correlate threat intelligence between security and network devices,

centrally manage and orchestrate policies, automatically synchronize resources to enforce policies, and coordinate a response to threats detected anywhere across the extended network. The unified management interface provides you with cooperative security alerts, recommendations, audit reports, and full policy control across the Security Fabric that will give you confidence that your network is secure.

## Access security

The Security Fabric secures the access layer of your organization's network. It integrates various access points in a network, such as endpoints, applications, the cloud, and IoT devices, regardless of their distribution, into an end-to-end solution that covers all attack surfaces.

Secure access architecture extends coordinated security policies to the edge of the wired and wireless network, where most vulnerabilities are targeted. It protects the access layer, guarding against data breaches and cybersecurity threats from both internal user devices and IoT products.

## Client security

Fortinet's client security, through FortiClient, provides easy-to-manage, automated, fully customizable endpoint security for various devices. FortiClient provides end-to-end threat visibility and control by natively integrating endpoints into the security architecture and offers unified endpoint features, including compliance, protection, and secure access. It also offers integrated patch management and vulnerability shielding to harden all endpoints.

FortiClient integrates with the Security Fabric to provide real-time actionable visibility to stop threats to your organization's network at the endpoints.

For more information about FortiClient, see <http://www.forticlient.com/>.

## Application security

The Security Fabric protects your organization's sensitive and proprietary data that is managed by applications, and ensures the security and availability of your organization's applications. It allows Fortinet application security products, and those of third-party vendors, to work together to boost security across core networks, remote devices, and the cloud. This provides your organization with a network architecture that is secure, aware, actionable, scalable, and open.

Fortinet's robust and integrated application security solution provides a complete end-to-end high-performance solution that protects your organization's valuable information by using a combination of Fortinet products which are deeply integrated into the Security Fabric for direct communications. These products include web application firewalls for application security, DDoS attack mitigation appliances for DDoS protection, advanced application delivery controllers (ADCs) to meet the demands of secure application traffic, sandboxing to isolate malicious code for inspection, and email security gateways that can detect and prevent email-borne threats from getting to your users.

## Cloud security

The Security Fabric is designed to extend deep into different cloud environments to ensure that policies are consistent and enforced across all distributed resources. Within the unified security architecture, virtual firewalls can be deployed across private, public, and hybrid clouds to establish north-south and east-west microsegmentation. The Security Fabric weaves cloud applications into the broader environment, governed by seamless, universal security and compliance policies and managed using transparent visibility across the entire attack surface. Combining Fortinet Cloud Security with an existing enterprise firewall deployment extends the same powerful security, as well as the same intelligence and dynamic risk mitigation to applications located either in the cloud or on-premise.

## NOC and SOC security

Fortinet's security operations center solution covers both IT and security risk management across your entire organization. The solution is a comprehensive approach to managing risk that includes adaptive awareness of the threat landscape, rapid local and global threat detection, reduced complexity in managing alerts and alarms, and reporting and analytics so you can better understand how your organization's risk profiles are being managed.

When Fortinet devices are unified into a Security Fabric, with compatible operating systems and shared intelligence, the security operations solution also includes information from network elements beyond Fortinet devices. The solution allows your network operations center (NOC) and security operations center (SOC) to share information, integrating and cross-correlating the data from each operations center. This additional context, visibility, and focus breaks down the barrier between your NOC and SOC, and gives you a comprehensive view across your entire Security Fabric so you can quickly find and respond to threats.

## Advanced threat intelligence

Fortinet's Advanced Threat Protection (ATP) solution allows your organization to detect and mitigate against threats, both known and unknown, and share that information locally to deliver a coordinated defence.

The ATP solution relies on many types of security technologies, products, and research applied from the network edge through to endpoint devices. To deliver the most effective protection, they are integrated with other security elements from the Enterprise Firewall and Cloud solutions to work together automatically, continuously handing off data from one element to the next to identify, evaluate, and respond to attacks across the entire environment.

The ATP framework delivers end-to-end protection across the attack chain and consists of three elements: prevention, detection, and mitigation, with continuous threat monitoring and analytics from FortiGuard Labs.

For more information about the Advanced Threat Protection Solution, see <http://www.fortinet.com/atp>.

## Partner API

The Fortinet Fabric-Ready Partner Program is an interoperability program for technology alliance partners. Technology alliance partners integrate their products with the Fortinet Security Fabric using Fortinet Security Fabric APIs. Their products are then able to actively collect and share threat and mitigation information from one end of the security solution to the other, which improves threat intelligence, enhances overall threat awareness, and broadens threat response.

Inclusion in the program means that Fabric-Ready Partners have collaborated with Fortinet and leveraged the Fortinet Security Fabric APIs to develop and validate integrated end-to-end security solutions that are ready for deployment.

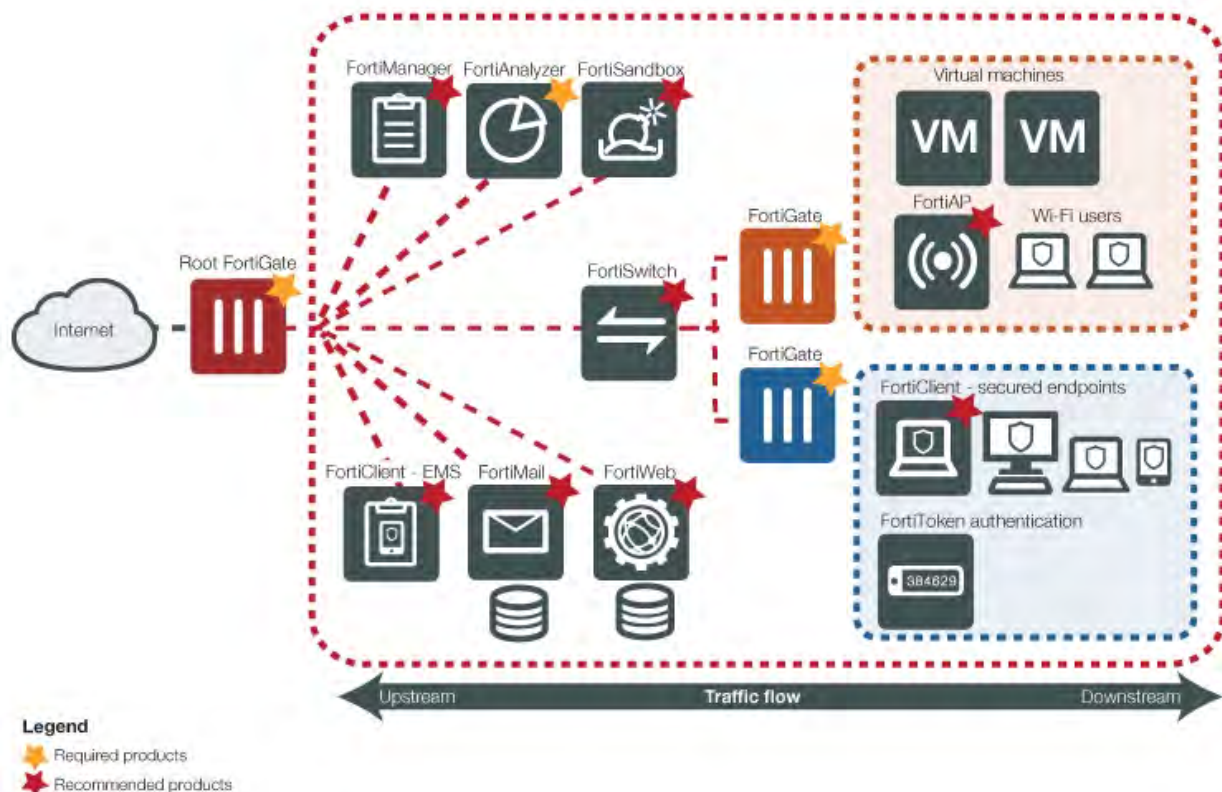

The Fabric-Ready Partner Program allows Fortinet technology alliance partners to build on Fortinet products and solutions which help your organization get even more value from your security deployment.

For more information about the Fortinet Fabric-Ready Partner Program, see <https://www.fortinet.com/content/dam/fortinet/assets/brochures/Fortinet-Fabric-Partner-Program.pdf>.

## The Security Fabric solution components

The Fortinet Security Fabric consists of various components that work together to form the Security Fabric that secures your organization's network. The following diagram shows an example Security Fabric that contains both required and recommended Fortinet products:

## Devices in the Security Fabric

The Security Fabric implementation consists of required, recommended, and optional devices.

## Required devices

The following table shows devices that are required in the Fortinet Security Fabric:

| Device        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FortiGate     | <p>FortiGate is a next-generation firewall (NGFW) that provides enterprise-class protection against network, content, and application-level threats.</p> <p>FortiGates are the core of the Security Fabric and can have one of the following roles in the Security Fabric:</p> <ul style="list-style-type: none"><li>• <b>Root FortiGate:</b> The root FortiGate is the main component in the Security Fabric. It is typically located on the edge of the network and connects the internal devices and networks to the Internet through your ISP. From the root FortiGate, you can see information about the entire Security Fabric from the Physical and Logical Topology pages in the Security Fabric menu.</li><li>• <b>Internal Segmentation Firewall (ISFW):</b> After a root FortiGate is installed, all other FortiGates in the Security Fabric act as ISFWs. An ISFW is a firewall that is located at strategic points in your internal network, rather than on the network edge. This allows extra security measures to be taken around key network components, such as servers that contain valuable intellectual property. ISFW FortiGates create network visibility by sending traffic and information about the devices that are connected to them to the root FortiGate.</li></ul> |
| FortiAnalyzer | <p>FortiAnalyzer collects, analyzes, and correlates log data from Fortinet devices throughout your organization's network, and allows you to view all firewall traffic and generate reports from a single console.</p> <p>FortiAnalyzer gives you increased visibility into your organization's network and simplifies network logging by storing and displaying all log information in one place. It provides centralized monitoring and awareness of threats, events, and network activity by collecting and correlating logs from Security Fabric devices, such as FortiGate, FortiClient, FortiSandbox, FortiWeb, and FortiMail. This gives you a deeper and more comprehensive view across your entire Security Fabric. You can use the robust security alert information and real-time threat intelligence that FortiAnalyzer provides to quickly identify and respond to security threats across your organization's network.</p>                                                                                                                                                                                                                                                                                                                                                          |

## Recommended devices

The following table shows devices that Fortinet recommends you have in the Fortinet Security Fabric:

| Device  | Description                                                                                                                                                                                                                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FortiAP | <p>FortiAP is a wireless access point that provides integrated, secure, identity-driven wireless LAN access for your organization's network.</p> <p>You can add FortiAPs to extend the Security Fabric to your wireless devices. Devices connected to a FortiAP appear in the Physical and Logical Topology pages in the Security Fabric menu.</p> |

| Device          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FortiClient     | <p>FortiClient adds endpoint control to devices that are located in the Security Fabric, allowing only traffic from compliant devices to flow through the FortiGate. This is done through FortiClient profiles.</p> <p>In the Security Fabric, FortiClient profiles are applied by the first FortiGate that a device's traffic flows through. This is often an ISFW FortiGate. Device registration and on-net status information for a device that is running FortiClient appears only on the FortiGate that applies the FortiClient profile to the device.</p>                     |
| FortiClient EMS | <p>FortiClient Enterprise Management Server (EMS) is a security management solution that provides scalable and centralized management of multiple endpoint devices.</p> <p>FortiClient EMS is used in the Security Fabric to provide visibility across your network, to securely share information and assign security profiles to endpoints.</p>                                                                                                                                                                                                                                   |
| FortiMail       | <p>FortiMail is a secure email gateway that uses various threat prevention methods, including antispam, antimalware, sandboxing, and anomaly detection.</p> <p>FortiMail integrates with other Fortinet products, as well as third-party virtual and cloud platforms, to help establish a seamless Security Fabric across the entire attack surface. FortiMail anti-spam processing helps offload other devices in the Security Fabric that would typically carry out this process.</p>                                                                                             |
| FortiManager    | <p>FortiManager is an easy-to-use, single pane of glass management console, that gives you total visibility, full control, and complete protection of your organization's network.</p> <p>Using the FortiManager in the Security Fabric allows you to simplify the network management of devices in the Security Fabric by centralizing management access in a single device. This allows you to easily control the deployment of security policies, FortiGuard content security updates, firmware revisions, and individual configurations for devices in the Security Fabric.</p> |
| FortiSandbox    | <p>FortiSandbox is an advanced threat protection appliance that improves your security architecture by identifying and validating threats in a separate, secure environment.</p> <p>You can add FortiSandbox to your Security Fabric to improve security with sandbox inspection. Sandbox integration allows FortiGates in the Security Fabric to automatically receive signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list.</p>                                                                                            |

| Device      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FortiSwitch | <p>FortiSwitch is a secure access switch that can be integrated into the Fortinet Security Fabric through the FortiLink protocol. FortiLink allows FortiSwitch ports to become logical extensions of the FortiGate. This allows the FortiGate to auto-discover a connected FortiSwitch for provisioning, including the attachment of policy to ports or VLANs. With an integrated access layer, the FortiGate provides consolidated visibility and reporting with Physical and Logical Topology views of the Security Fabric in the Security Fabric menu.</p> <p>You can add a FortiSwitch to the Security Fabric when it is managed by a FortiGate within the Security Fabric, and connected to an interface that uses FortiTelemetry.</p> <p>Devices connected to the FortiSwitch appear in the Physical and Logical Topology pages in the Security Fabric menu, and security features, such as FortiClient profiles, are applied to them.</p> |
| FortiWeb    | <p>FortiWeb is a web application firewall that protects hosted web applications from attacks that target known and unknown exploits.</p> <p>In the Security Fabric, FortiWeb defends the application attack surface from attacks that target application exploits. You can also configure FortiWeb to apply web application firewall features, virus scanning, and web filtering to HTTP traffic to help offload other devices in the Security Fabric that would typically carry out these processes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Optional devices

The following table shows devices that are optional in the Fortinet Security Fabric:

| Device                  | Description                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Other Fortinet products | Many other Fortinet products can be added to the Security Fabric, including FortiAuthenticator, FortiToken, FortiCache, and FortiSIEM. |
| Third-party products    | Third-party products that belong to the <a href="#">Fortinet Fabric-Ready Partner Program</a> .                                        |

## Security Fabric topology views

You can see the Security Fabric topology in the root FortiGate GUI. Two viewing options are available: the Physical Topology view and the Logical Topology view.

The Physical Topology view displays the physical structure of your network, by showing the devices in the Security Fabric and the connections between them. The Logical Topology view displays the logical structure of your network, by connection, by showing information about logical and physical network interfaces in the Security Fabric and the interfaces that connect devices in the Security Fabric. Only Fortinet devices are shown in the topology views.

For more information about the topology views, see [Viewing the Security Fabric topology](#).

## Security Fabric Audit

The Security Fabric Audit provides a method to continually monitor and improve your organization's Security Fabric configuration. The Security Fabric Audit is a feature on the FortiGate that analyzes your Security Fabric deployment, identifies potential vulnerabilities, and highlights best practices that you can use to improve the overall security and performance of your network. Using the Security Fabric Audit helps you to:

- Tune your network configuration
- Deploy new hardware and software
- Have more visibility into your network
- Gain more control over your network
- Adhere to your organization's compliance requirements

The Security Fabric Audit provides a Security Fabric Score based on how many checks your network passes and fails during the Security Fabric Audit. By checking the Security Fabric Score, and implementing the recommendations, you can have confidence that your network is getting more secure over time.

For more information about running a Security Fabric Audit, see [Running a Security Fabric Audit](#).

## FortiTelemetry

FortiTelemetry is a protocol that Fortinet products in the Security Fabric use to communicate with each other. It connects Security Fabric devices and allows dynamic status updates to travel between them. The Security Fabric uses FortiTelemetry to link various security sensors and tools together to collect, coordinate, and respond to malicious behavior anywhere it occurs in your network in real time.

You must enable FortiTelemetry on interfaces that connect Fortinet devices in the Security Fabric.

## Configuring the Security Fabric

To configure the Security Fabric, you must form the Security Fabric and then set up data collection for the Security Fabric.

Setting up data collection includes configuring the FortiAnalyzer so that the entire Security Fabric is recognized by the FortiAnalyzer. Once this is done, the root FortiGate and downstream FortiGates can show information about all downstream FortiGates and other devices that are connected to them. Then you can use the Security Fabric features to view, assess, and improve your organization's network security.

### System requirements

To set up the Security Fabric in FortiOS 5.6, the devices that you want to include in the Security Fabric must meet the following requirements. Some features of the Security Fabric are available only in certain firmware versions.

| Device          | Requirement                                                                                                                                                                                                                             | Feature conditions                                            |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| FortiGate       | <ul style="list-style-type: none"><li>• Version 5.6 and later</li><li>• All ISFW FortiGates should be running the same firmware version as the root FortiGate</li><li>• FortiGate is a required device in the Security Fabric</li></ul> |                                                               |
| FortiAnalyzer   | <ul style="list-style-type: none"><li>• Version 5.6 and later</li><li>• Logging to the FortiAnalyzer must be enabled</li><li>• FortiAnalyzer is a required device in the Security Fabric</li></ul>                                      |                                                               |
| FortiClient     | Version 5.6 and later                                                                                                                                                                                                                   |                                                               |
| FortiClient EMS | Version 1.2 and later                                                                                                                                                                                                                   |                                                               |
| FortiAP         | Version 5.4 and later                                                                                                                                                                                                                   | Version 5.6 and later is recommended to access all features   |
| FortiSwitch     | Version 3.5.2 and later                                                                                                                                                                                                                 | Version 3.5.3 and later is recommended to access all features |

For more information about upgrading the Security Fabric to version 5.6, see the [Security Fabric Upgrade guide](#).

### Prerequisites

- Determine which devices you want to have in the Security Fabric
- Ensure devices meet the [System requirements](#)

- If devices are not already installed in your network, complete basic installation and configuration tasks by following the instructions in the device documentation
- Disable virtual domains (VDOMs) on all FortiGate devices that you want to add to the Security Fabric
- Configure all FortiGate devices that you want to add to the Security Fabric to use NAT mode

### Forming the Security Fabric

To form the Security Fabric, you configure the root FortiGate and then the ISFW FortiGate devices. Although you can configure any of the FortiGate devices in the Security Fabric to be the root FortiGate, you typically configure the edge FortiGate as the root FortiGate. This setup allows you to view the full topology of the Security Fabric from the top down.

The following procedures include configuration steps for a typical Security Fabric implementation, where the root FortiGate is the edge FortiGate and the ISFW FortiGate devices are all FortiGate devices that are downstream from the root FortiGate.

#### Configure the root FortiGate for the Security Fabric

1. In the root FortiGate GUI, select **Security Fabric > Settings**.
2. In the Security Fabric Settings page, enable **FortiGate Telemetry**.
3. In the **Group name** field, set a name for the Security Fabric group.
4. In the **Group password** field, set a password for the Security Fabric group.
5. Ensure that **Connect to upstream FortiGate** is disabled.
6. In the **FortiTelemetry enabled interfaces** field, add the interfaces on this FortiGate that listen for downstream Security Fabric connections.  
The **FortiAnalyzer Logging** setting is automatically enabled.
7. In the **IP address** field, enter the IP address of the FortiAnalyzer that you want the Security Fabric to send logs to. If you select **Test Connectivity**, and this is the first time that you are connecting the FortiGate to the FortiAnalyzer, you will receive an error message because the FortiGate has not yet been authorized on the FortiAnalyzer. You can configure this authorization when you configure the FortiAnalyzer.
8. In the **Upload option** field, select the option for how often you want the FortiGate to send logs to the FortiAnalyzer.
9. If you want log transmissions encrypted, enable the **Encrypt log transmission** option. The log transmissions are encrypted using SSL.
10. Select **Apply**.

## Configure ISFW FortiGates for the Security Fabric

1. In the ISFW FortiGate GUI, select **Security Fabric > Settings**.
2. In the Security Fabric Settings page, enable **FortiGate Telemetry**.
3. In the **Group name** field, enter the group name that you set for the Security Fabric.
4. In the **Group password** field, enter the group password that you set for the Security Fabric.
5. Enable the **Connect to upstream FortiGate** option.
6. In the **FortiGate IP** field, enter the IP address of the port on the upstream FortiGate that this FortiGate connects to. Depending on your network topology, the upstream FortiGate is another ISFW FortiGate or the root FortiGate. The FortiAnalyzer setting is automatically enabled. Settings for the FortiAnalyzer will be retrieved when the ISFW FortiGate connects to the root FortiGate.
7. Select **Apply**.
8. Repeat this procedure on every ISFW in the Security Fabric.

## Setting up data collection for the Security Fabric

To set up data collection for the Security Fabric, you enable device detection on ISFW FortiGates and then connect the FortiAnalyzer to the Security Fabric.

You enable device detection on the interfaces of the ISFW FortiGates where you want the devices attached to those interfaces added to the Security Fabric. Only devices detected on those interfaces are shown in the Security Fabric topology views.

Connecting the FortiAnalyzer to the Security Fabric allows the Security Fabric to show historical data for the Security Fabric topology and logs for the entire Security Fabric.

## Enable device detection on ISFW FortiGates

1. In the ISFW FortiGate GUI, select **Network > Interfaces**.
2. Select the interface that you want to enable device detection on.
3. Select **Edit**.
4. In the **Addressing mode** field, select **Manual**.
5. In the **IP/Network Mask** field, enter a private IP address and network mask.
6. If you have FortiClient clients behind this interface, in the **Administrative Access** section, enable **FortiTelemetry**.
7. If you require the FortiGate to provide IP addresses using DHCP to devices that connect to this interface, enable **DHCP Server**. Suitable address ranges are automatically created.
8. In the **Networked Devices** section, enable **Device Detection**.
9. Select **OK**.
10. Repeat this procedure for every interface that you want to enable device detection on.

## Connect the FortiAnalyzer to the Security Fabric

---

Ensure that all FortiGates in the Security Fabric are registered with the same FortiAnalyzer.

---

1. In the FortiAnalyzer GUI, select **System Settings > Network**.
2. Select **All Interfaces**.
3. Select the port that connects to the root FortiGate.
4. Select **Edit**.
5. In the **IP Address/Netmask** field, enter the IP address used for the Security Fabric configuration on the root FortiGate.
6. In the **Default Gateway** field, enter the IP address of the interface on the root FortiGate that the FortiAnalyzer connects to.
7. Select **OK**.
8. Select **System Settings > Device Manager**.  
The FortiGates are listed as **Unregistered**.
9. Select the root FortiGate and the ISFW FortiGates in the Security Fabric.
10. Select **+ Add Device**.  
The FortiGates are now listed as **Registered**.  
A warning icon will appear beside the root FortiGate, because the FortiAnalyzer requires administrative access to the root FortiGate in the Security Fabric.
11. In the **Authentication** window, complete the **Admin User** and **Password** fields to authenticate the Security Fabric.  
After the FortiAnalyzer authenticates the Security Fabric, the FortiAnalyzer shows the full Security Fabric topology.

You can verify that the FortiAnalyzer configuration is successful by selecting **Security Fabric > Settings** on the root and ISFW FortiGates. The **Storage usage** field in the **FortiAnalyzer Logging** section should now show storage usage information.

## Using the Security Fabric to improve network security

Once you set up the Security Fabric, there are various Security Fabric features that you can use to improve your network security, including the following:

- Dashboard widgets
- Topology views
- Security Fabric Audit
- Monitoring views

### Understanding the Security Fabric dashboard widgets

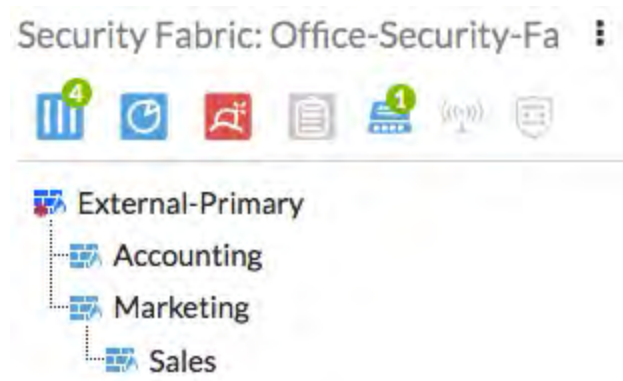

You can add Security Fabric widgets to the dashboard on the root FortiGate. There are two widgets available: the Security Fabric widget and the Security Fabric Score widget. The widgets allow you to see information about the status of the Security Fabric when you first log in to the FortiGate.

If either of these widgets do not appear on your dashboard, you can add them using the settings button in the bottom right corner. This button appears when your mouse hovers over any part of the dashboard.

On the root FortiGate, select **Dashboard > Main**.

#### The Security Fabric widget

The Security Fabric widget shows a visual summary of many of the devices in the Security Fabric. You can hover over the icons at the top of the widget to get a quick view of the status of the Security Fabric, including the status of FortiTelemetry and devices in the Security Fabric.

The widget shows the following information:

- The name of your Security Fabric
- Icons indicating the other Fortinet devices that can be used in the Security Fabric:
  - Devices in blue are detected in your network
  - Devices in gray are not detected in your network
  - Devices in red are not detected in your network, but are recommended for the Security Fabric
- The names of the FortiGates in the Security Fabric

## The Security Fabric Score widget

The Security Fabric Score widget shows the latest Security Fabric Audit score and allows you to apply audit recommendations from the dashboard.

The widget shows the following information:

- The time that the score was last calculated
- The Security Fabric score
- A list of the number of checks that were not passed, ranked by the following severities: Critical, High, Medium, and Low

## Viewing the Security Fabric topology

You can see the Security Fabric topology in the FortiGate GUI, in the Security Fabric menu. You can choose the Physical Topology or Logical Topology views. In both topology views, you can hover over device icons and use filtering and sorting options to see more information about devices and your organization's network. To view the complete network, you must access the topology views on the root FortiGate in the Security Fabric.

You can also see the Security Fabric topology in the FortiAnalyzer GUI. In the FortiAnalyzer GUI, select **Device Manager**. The FortiGates in the Security Fabric are shown as part of a Security Fabric group. An asterisk (\*) appears beside the root FortiGate in the Security Fabric. To see the topology of the Security Fabric, right-click on the Security Fabric group and select **Fabric Topology**.

Only Fortinet devices are shown in the Security Fabric topology views.

## View the Physical Topology

To see the Physical Topology, in the root FortiGate GUI, select **Security Fabric > Physical Topology**.

The Physical Topology view displays your network as a bubble chart of interconnected devices. These devices are grouped based on the upstream device they are connected to. The bubbles appear smaller or larger, based on their traffic volume. You can double-click any bubble to resize it and view more information about the device.

Security Fabric Audit recommendations are also shown in the topology, beside the icon of the device the recommendations apply to.

The Logical Topology view is similar to the Physical Topology view, but it shows the network interfaces, logical or physical, that are used to connect devices in the Security Fabric.

The Logical Topology view displays your network as a bubble chart of network connection points. These devices are grouped based on the upstream device interface they are connected to. The bubbles appear smaller or larger, based on their traffic volume. You can double-click any bubble to re-size it.

Security Fabric Audit recommendations are also shown in the topology, beside the icon of the device the recommendations apply to.

### Filter the topology views by specific criteria

You can use filters to narrow down the data on the topology views, so you can find specific information.

1. In the drop-down menu to the right of the **Search** field, select one of the following:
  - Device Traffic
  - Device Count
  - Device Type
  - Vulnerability
  - Threat Score
  - No Device
2. To filter the view by time, in the time period drop-down menu, select one of the following:
  - now
  - 5 minutes
  - 1 hour
  - 24 hours
  - 7 days
3. To sort the topology by traffic options, in the **Sort By** drop-down menu, select one of the following:
  - Bytes (Sent/Received)
  - Packets (Sent/Received)
  - Bandwidth
  - Session

## Running a Security Fabric Audit

You can run a Security Fabric Audit to analyze your organization's Security Fabric deployment, identify potential vulnerabilities, and highlight best practices that you can use to improve the overall security and performance of your organization's network.

The Security Fabric Audit performs a variety of checks when it analyzes your network. All checks are based on your current network configuration, using real-time monitoring. The audit runs the checks across all FortiGate in the Security Fabric.

When the audit is complete, a list of recommendations is shown. Two views are available: Failed or All Results. You can filter these views further in order to view results from a specific FortiGate or all FortiGates. Each view has a chart that shows the results of individual checks, and includes the name and a description of the check, which FortiGate the check was performed on, the impact of the check on the overall security score, and recommendations. If you hover over the result for a check, you can see a breakdown of how the score was determined.

You can choose to automatically apply the recommendations that include the Easy Apply option. By using Easy Apply, you can change the configuration of any FortiGate in the Security Fabric. Further action is required if you want to follow other recommendations.

You can also view audit recommendations for specific devices in the Physical and Logical Topology views in the Security Fabric menu. If a recommendation is available for a device, a circle containing a number appears. The

number shows how many recommendations are available. The color of the circle shows the severity of the highest check that failed. The following table shows the severity that each color represents:

| Color  | Severity |
|--------|----------|
| Red    | Critical |
| Orange | High     |
| Yellow | Medium   |
| Blue   | Low      |

For more information about the Security Fabric Audit, and details about each of the audit checks that are performed, see the [Fortinet Recommended Security Best Practices](#) document.

## Run a Security Fabric Audit

You must run the Security Fabric Audit on the root FortiGate in the Security Fabric.

1. In the root FortiGate GUI, select **Security Fabric > Audit**.  
In the **Detect Security Fabric FortiGates** step, all FortiGates in the Security Fabric are listed.
2. To run the audit, select **Next**.  
The Audit will run. When it completes, the **Audit** step is displayed, which shows the following information:
  - The **Security Score** field shows the score for your Security Fabric
  - The page shows the overall count of how many checks passed or failed, with the failed checks divided by severity
  - Information about each failed check, including which FortiGate failed the check, the effect of the check failure on the security score, and recommendations to fix the issue
  - The **Easy Apply** option appears with recommendations that can be automatically applied by the wizard
3. To move to the **Easy Apply** option page, select **Next**.
4. Select all recommendations that you want to implement in the Security Fabric.
5. Select **Apply Recommendations**.

## Set up logging for the Security Fabric Audit

You can configure an event filter subtype for the Security Fabric Audit. When you run an audit, event logs are created on the root FortiGate that summarize the results of the audit and show detailed information for the individual tests.

To configure logging for the Security Fabric Audit, use the following CLI commands:

```
config log eventfilter
 set security-audit {enable | disable}
end
```

## Understanding the Security Fabric Score

When you run a Security Fabric Audit, your organization's Security Fabric receives a Security Fabric Score. The score will be positive or negative, and a higher score represents a more secure network.

The score is based on how many checks your network passes and fails, as well as the severity level of these checks. The following table shows the weight for each severity level:

| Severity level | Weight    |
|----------------|-----------|
| Critical       | 50 points |
| High           | 25 points |
| Medium         | 10 points |
| Low            | 5 points  |

The audit awards points when a check passes, using the following formula:

$$+ \text{<Severity Weight>} \times \text{<Secure FortiGate Multiplier>}$$

where:

- *Severity Weight* is  $\text{<Severity level>} / \text{<number of FortiGates in the Security Fabric>}$
- *Secure FortiGate Multiplier* is determined using logarithms and the number of FortiGates in the Security Fabric

For example, if you have four FortiGates in the Security Fabric, and all of them pass the Compatible Firmware check, the score for each FortiGate is calculated as:  $(50/4) \times 1.292 = 16.2$  points.

All FortiGates in the Security Fabric must pass the check in order to receive points. If any of the FortiGates in the Security Fabric fail a check, any FortiGates in the Security Fabric that passed the check are not awarded points. For the FortiGate that failed the test, the score is calculated using the following formula:

$$- \text{<Severity Weight>} \times \text{<Count>}$$

where:

- *Severity Weight* is  $\text{<Severity level>}$
- *Count* is the number of times the check failed during the audit

For example, if the audit finds two critical FortiClient vulnerabilities, the score for that check is calculated as:  $-50 \times 2 = -100$  points.

The score is not affected by checks that do not apply to your network. For example, if you do not have any FortiAPs in the Security Fabric, you will not receive any points for the FortiAP Firmware Versions check.

## Viewing monitoring information for devices in the Security Fabric

The Security Fabric retrieves monitoring information from all devices in the Security Fabric and displays it in the monitor pages in the root FortiGate GUI.

### View monitoring information for a specific device in the Security Fabric

1. In the root FortiGate GUI, select **Monitor**.
2. Select the monitor page that you want to view. For example, **Routing Monitor** or **Quarantine Monitor**.
3. In the drop-down menu, select the device in the Security Fabric that you want to see monitoring information for.

# Chapter 25 - Security Profiles

## Security profiles

Welcome and thank you for selecting Fortinet products for your network protection.

The following chapter describes the Security Profile features available on your FortiGate unit, including antivirus, intrusion prevention system (IPS), web filtering, email filtering, data leak prevention, (DLP) and application control. The guide includes step-by-step instructions showing how to configure each feature. Example scenarios are included, with suggested configurations.

Examples include scenarios using web filtering to protect users from inappropriate content, using IPS to protect web servers from attack, and using antivirus scanning to protect your network against viruses and malicious file attachments.

## Before you begin

Before you begin using this guide, take a moment to note the following:

Administrators are assumed to be super\_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.

Firewall policies limit access, and, while this and other similar features are a vital part of securing your network, they are not covered in this guide.

If your FortiGate unit supports SSL acceleration, it also supports SSL content scanning and inspection for HTTPS, IMAPS, POP3S, and SMTPS traffic.

## How this chapter is organized

This FortiOS Handbook chapter contains the following sections:

- [What's New in FortiOS 5.6](#) describes the new security profile features in FortiOS 5.6.
- Inside FortiOS highlights the features and benefits of key FortiOS 5.6 components. The technical documentation team maintains these documents as part of the Handbook and as standalone documents which are available at Fortinet's Online Help. Inside FortiOS covers the following security profiles topics:
  - [AntiVirus](#)
  - [Application Control](#)
  - [Intrusion Prevention System](#)
  - [Web Filtering](#)
- [Security Profiles overview](#) describes Security Profiles components and their relation to firewall policies, as well as SSL content scanning and inspection.
- [Inspection Modes](#) discusses the FortiGate's inspection modes and how the security profiles function depending on inspection mode.
- [AntiVirus](#) explains how the FortiGate unit scans files for viruses and describes how to configure the antivirus options.

- [Web filter](#) describes basic web filtering concepts, FortiGuard Web Filtering, the order in which the FortiGate unit performs web filtering, and configuration.
- [DNS filter](#) explains how to configure the Domain Name System (DNS) Filter security profile independent of the Web Filter security profile.
- [Application Control](#) describes how your FortiGate unit can detect and take action against network traffic based on the application generating the traffic.
- [Intrusion prevention](#) explains basic Intrusion Protection System (IPS) concepts and how to configure IPS options; includes guidance and a detailed table for creating custom signatures as well as several examples.
- [Anti-Spam filter](#) explains how the FortiGate unit filters email, how to configure the filtering options, and which actions to take when spam is detected.
- [Data leak prevention](#) describes the DLP features that allow you to prevent sensitive data from leaving your network and explains how to configure the DLP rules, compound rules, and sensors.
- [ICAP support](#) describes how to offload traffic to a separate server specifically set up for the specialized processing of the traffic.
- [FortiClient Profiles](#) addresses the FortiClient Profiles endpoint protection features and configuration.
- [SSL/SSH Inspection](#) presents SSL and SSH content scanning and inspection with your FortiGate.
- [Custom Application & IPS Signatures](#) describes how to create custom Application Control and IPS signatures.
- [Other Security Profiles considerations](#) addresses topics like Security Profiles VDOMs, conserve mode, using wildcards and Perl regular expressions, adding External Security Devices, CPU allocation and tuning commands to survive reboot and so on.

## What's new in FortiOS 5.6

This chapter describes new Security Profile features added to FortiOS 5.6.

### FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

- "Configuring the FortiClient offline grace period" on page 2921
- "Excluding industrial IP signatures" on page 2958

### FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

#### Added multiple ports and port range support in the explicit ftp/web proxy (402775)

Added multiple ports and port range support in the explicit ftp/web proxy:

- added new monitor api endpoint for checking whether a list of TCP port ranges is being used, sample usage: `/api/v2/monitor/system/check-port-availability?port_ranges=[{"start":8080,"end":8080},{"start":400,"end":600}, {"start":1,"end":200}]&service=webproxy`
- added GUI support for port ranges in web-proxy and ftp-proxy settings

#### Block access to unsupported FortiClient endpoints (457695)

You can use the following command to deny registration of unsupported FortiClients endpoints. An unsupported FortiClient endpoint means the endpoint is running FortiClient but for some reason not all of the criteria are available to identify the endpoint, or the endpoint may be running an unsupported version of FortiClient. Information required that is not available could include the endpoint's IP address or MAC address is not visible.

```
config endpoint-control setting
 set forticlient-dereg-unsupported-client {enable | disable}
end
```

#### Exempt list fix (381762)

The FortiClient Monitor page now shows exempt device types, as opposed to just the device category. FortiOS can now differentiate the three cases both from backend and GUI.

#### Backend changes

Differentiate the three cases:

- exempt by custom device
- exempt by device category
- exempt by device group

#### GUI changes

1. **Monitor > FortiClient Monitor** page:

- show device exempt reasons as any combination of device, device category, device group, source address.
2. Update REST monitor api
    - (URI: /api/v2/monitor/user/device/select?compliance\_visibility=true)
    - update "exempt\_reason" field from string to array of strings in json result

## FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

### FortiGuard WAN IP blacklist service is now online (404859)

The Fortiguard WAN IP blacklist service was not online in FortiOS 5.6.0. In FortiOS 5.6.1, a notification appears on the **Dashboard** when WAN IP is blacklisted. Clicking on the notification brings up the blacklist details.

### Application Control GUI improvements (279956)

An **All Categories** button on the **Security Profiles > Application Control** page makes it easier to apply an action (Monitor, Allow, Block, Quarantine) to all categories at once.

Note that the **All Categories** selector goes blank when any of the actions to be applied to individual categories is manually changed to something different than what was selected for all the categories. The **Unknown Application** action will match the **All Categories** action unless that action is Quarantine, which is unsupported for unknown applications.

### Industrial Application Control signatures (434592)

The application control category Industrial is now controlled by a FortiGuard license and the default disable mask is no longer needed. The special category is also no longer used.

### GUI updates to reflect package and license changes for IPS, Application Control and Industrial signatures (397010)

The following changes have been made to the GUI to reflect changes in the signature databases:

- Application Control signature database information is displayed under on the **System > FortiGuard** page in the FortiCare section.
- The IPS package version and license status are shown in a separate section in **System > FortiGuard** page. A link to manually upload the IPS database signatures has been added.
- The Industrial package version and license status are shown in a separate section in **System > FortiGuard** page. A link to manually upload the Industrial database signatures is available. Access to the Industrial database is provided with the purchase of the FortiGuard Industrial Security Service. The row item for this license will not appear if you are not subscribed.
- Botnet category is no longer available when searching the Application Signatures list.

### Improved FortiClient monitor display (378288)

The GUI for the **Monitor > FortiClient Monitor** page has been revised.

- new dropdown option: **Online Only** or **Include Offline**. The default is **Online Only**.
- new dropdown option
  - **Sending FortiTelemetry Only** (default)
  - **Include All FortiTelemetry States**
  - **Not Sending FortiTelemetry Only**
- update: **Compliance** status for offline device is **N/A**
- update: offline status indicator to grey
- new compliance status text after the icon in **Compliance** column
- Moved **Compliance** column after **Status** column
- Combined unregistered endpoint devices with not registered devices

### FortiSandbox integration with AntiVirus in quick mode (436380)

FortiSandbox options in an AntiVirus Security Profile in quick scanning mode can now be enabled with CLI commands.

#### CLI syntax

```
config antivirus profile
edit default
set ftgd-analytics disable/everything
set analytics-max-upload 10
set analytics-wl-filetype 0
set analytics-bl-filetype 0
set analytics-db enable/disable
set scan-mode quick
end
```

### Pre-configured parental controls for web filtering (399715)

Pre-configured filters based on the Motion Picture Association of America (MPAA) ratings can now be added to the Web Filter Security Profile. This feature is already available on FortiCloud and uses the same ratings categories.

### Anti-Spam GUI updates (300423)

Changes made to the Anti-Spam profile update the GUI to reflect FortiOS 5.6 style.

## FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

### Application control is now standard with FortiCare support

Application Control is now a standard part of any FortiCare support contract and the database for Application Control signatures is separate from the Intrusion Prevention System (IPS) database. However, botnet application signatures are still part of the IPS signature database since these are more closely related to security issues than application detection.

With the release of FortiOS 5.6.1, the Application Control signature database information is displayed under the **System > FortiGuard** page, in the FortiCare section. The botnet category is no longer available when you search for the Application Signatures list.

To receive updates to the Application Control signature database, you must have a valid FortiCare support contract.

## IPS / Application Control logging performance

There is a major boost to Application Control and IPS when logging is enabled. With the latest changes, the performance difference with or without logging enabled is negligible.

## CASI functionality moved into application control (385183, 372103)

Cloud Access Security Inspection (CASI) is merged with Application Control resulting in changes to the GUI and the CLI.

### GUI Changes

- Toggle option added to quickly filter CASI signatures in the Application Signatures list.
- Application Overrides table now shows any parent-child hierarchy using the --parent metadata on signatures. Deleting a parent app also deletes its child apps. And conversely, adding a child app will add all its parent apps but with implicit filter action.
- A policy breakdown is shown on existing application control profiles for policies using the profile. The breakdown indicates which policies are using a deep inspection.
- A breakdown is shown for application categories and filter overrides to indicate the number of CASI and non-CASI signatures. A lock icon is shown for applications requiring deep inspection.

### CLI Changes

Commands removed:

- `config application casi profile`
- `casi profile in config firewall policy`
- `casi profile in config firewall policy6`
- `casi-profile-status` and `casi-profile under config firewall sniffer`
- `casi-profile-status` and `casi-profile under config firewall interface-policy`

## Application control and Industrial signatures separate from IPS signatures (382053)

IPS, Application control and industrial signatures have been separated. The `get system status` command shows the versions of each signature database:

```
get system status
Version: FortiGate-5001D v5.6.0,build1413,170121 (interim)
Virus-DB: 42.00330(2017-01-23 01:16)
Extended DB: 1.00000(2012-10-17 15:46)
Extreme DB: 1.00000(2012-10-17 15:47)
IPS-DB: 6.00741(2015-12-01 02:30)
IPS-ETDB: 0.00000(2001-01-01 00:00)
APP-DB: 6.00741(2015-12-01 02:30)
```

## Block Google QUIC protocol in default Application Control configuration (385190)

QUIC is an experimental protocol from Google. With recent Google Chrome versions (52 and above), and updated Google services, more than half of connections to Google servers are now in QUIC. This affects the accuracy of Application Control. The default configuration for Application control blocks QUIC.

Users may enable QUIC with CLI commands.

### CLI Syntax

```
config application list
edit <profile-name>
set options allow-quic
end
```

## FortiClient profile improvements (386267, 375049)

FortiClient profiles have been changed in FortiOS 5.6 to include new protection features and to change organization of the GUI options. FortiClient profiles also use the FortiGate to warn or quarantine endpoints that are not compliant with a FortiClient profile.

A bug that prevented the Dialog and Device Inventory pages from loading when there is a large number of devices (for example, 10,000) has been fixed.

## Default FortiClient profile

FortiClient profiles allow you to perform vulnerability scans on endpoints and make sure endpoints are running compliant versions of FortiClient. Also, security posture features cause FortiClient to apply realtime protection, AntiVirus, web filtering, and application control on endpoints.

|              |                                                       |
|--------------|-------------------------------------------------------|
| Profile Name | <input type="text" value="default"/>                  |
| Comments     | <input type="text" value="Write a comment..."/> 0/255 |

### Telemetry Data

Endpoints must send telemetry data to FortiGate for Security Fabric.  
Non-compliant endpoints will be issued a warning.

Non-compliance action ☐ Block ☒ Warning

☒ Endpoint Vulnerability Scan on Client

☐ System Compliance

☐ Security Posture Check

The default FortiClient profile also allows you to set a general **Non-compliance action** for endpoints that don't have FortiClient installed on them. The non-compliance action can be block or warning and is applied by the FortiGate. Blocked endpoints are quarantined by the FortiGate.

### Endpoint vulnerability scanning

Similar to FortiOS 5.4 you can set the FortiClient Profile to run the FortiClient vulnerability scanner on endpoints and you can set the Vulnerability quarantine level to quarantine endpoints that don't comply.

**Endpoint Vulnerability Scan on Client**

Vulnerability quarantine level ⓘ High

Non-compliance action Block **Warning**

The vulnerability scan **Non-compliance action** can block or warn endpoints if the vulnerability scan shows they do not meet the vulnerability quarantine level.

### System compliance

FortiOS 5.6 system compliance settings are similar to those in 5.4 with the addition of a non-compliance action. System compliance checking is performed by FortiClient but the non-compliance action is applied by the FortiGate.

**System Compliance**

Minimum FortiClient version 5.6.0

Windows endpoints 5.6.0

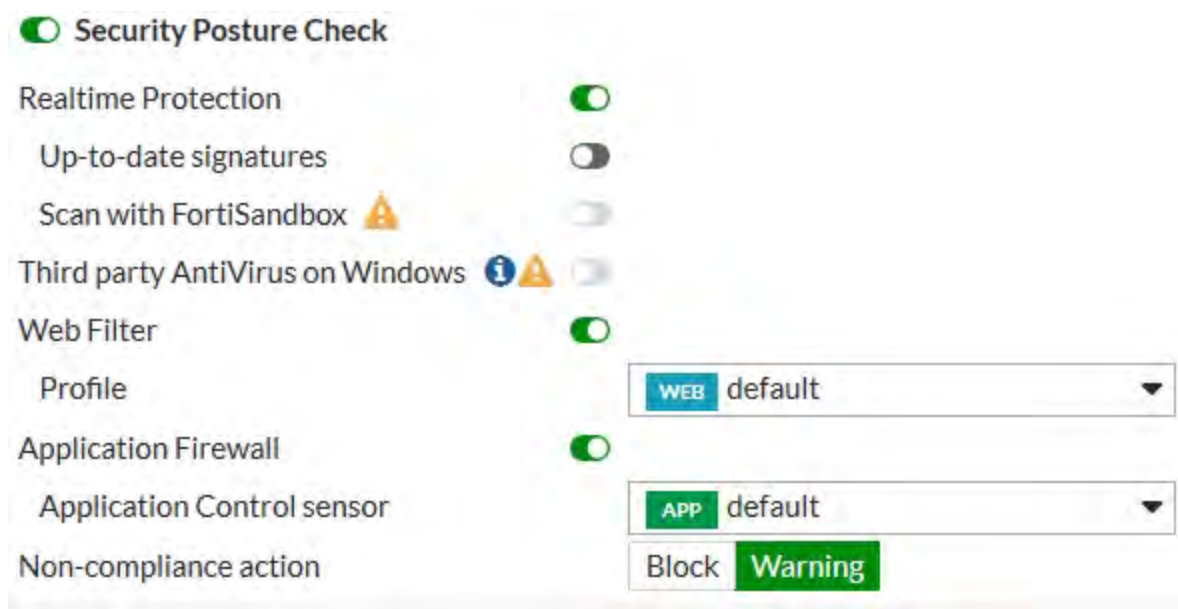

Mac endpoints 5.6.0

Upload Logs to FortiAnalyzer ⓘ 5.6.0 ☒ Traffic ☒ Event ☒ Vulnerability

Non-compliance action Block **Warning**

### Security posture checking

Security posture checking collects realtime protection, antivirus protection, web filtering and application firewall features under the **Security Posture Check** heading.

### FortiClient endpoint license updates (401721)

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum ([forum.fortinet.com](https://forum.fortinet.com)). Phone support is only available for paid licenses.

| Model(s)                            | Maximum client limit |
|-------------------------------------|----------------------|
| VM00                                | 200                  |
| FGT/FWF 30 to 90 series             | 200                  |
| FGT 100 to 400 series               | 600                  |
| FGT 500 to 900 series, VM01, VM02   | 2,000                |
| FGT 1000 to 2900 series             | 20,000               |
| FGT 3000 to 3600 series, VM04       | 50,000               |
| FGT 3700D and above, VM08 and above | 100,000              |

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

### FortiClient Vulnerability Exemption Setting (407230)

A new CLI command provides a manual override for client computers with vulnerabilities that cannot be fixed.

## CLI Syntax

New command to enable/disable compliance exemption for vulnerabilities that cannot be auto patched. Default is disable.

```
config endpoint-control profile
 edit <profile-name>
 config forticlient-winmac-setting
 set forticlient-vuln-scan enable
 set forticlient-vuln-scan-exempt [enable|disable]
 end
 next
end
```

## New FortiGuard Web Filter categories (407574)

New categories added to FortiGuard Web Filter sub-categories:

- Under Security Risk:
  - Newly Observed Domain (5.90)
  - Newly Registered Domain (5.91)
- Under General Interest - Business
  - Charitable Organizations (7.92)
  - Remote Access (7.93)
  - Web Analytics (7.94)
  - Online Meeting (7.95)

Newly observed domain (NOD) applies to URLs whose domain name is not rated and were observed for the first time in the past 30 minutes.

Newly registered domain (NRD) applies to URLs whose domain name was registered in the previous 10 days.

## Overall improvement to SSL inspection performance (405224)

The enabling / disabling of proxy cipher / kxp hardware acceleration in CP8/CP9 required restarting of the WAD daemon for the change to take effect; this bug has been repaired.

## New CLI commands

The FortiGate will use the `ssl-queue-threshold` command to determine the maximum queue size of the CP SSL queue. In other words, if the SSL encryption/decryption task queue size is larger than the threshold, the FortiGate will switch to use CPU rather than CP. If less, it will employ CP.

```
config firewall ssl setting
 set ssl-queue-threshold <integer>
end
```

The integer represents the maximum length of the CP SSL queue. Once the queue is full, the proxy switches cipher functions to the main CPU. The range is 0 - 512 and the default is 32.

## DNS profile supports safe search (403275)

Users can take advantage of pre-defined DNS doctor rules to edit DNS profiles and provide safe search for Google, Bing, and YouTube.

### To add safe search to a DNS profile - GUI

1. Go to **Security Profiles > DNS Filter**.
2. Edit the default filter or create a new one.
3. Enable **Enforce 'Safe Search on Google, Bing, YouTube'**.
4. Select **Strict** or **Moderate** level of restriction for **YouTube Access**.

### To add safe search to a DNS profile - CLI

```
config dnsfilter profile
 edit "default"
 set safe-search enable
 set youtube-restrict {strict | moderate} (only available is safe-search enabled)
 next
end
```

### Changes to default SSL inspection configuration (380736)

SSL inspection is mandatory in the CLI and GUI and is enabled by default.

#### GUI Changes

- Updated edit dialogues for IPv4/IPv6 Policy and Explicit Proxy Policy
  - SSL/SSH inspection data displayed in muted palette
  - disabled the toggle button for this option
  - set the default profile as "certificate-inspection"
- Updated list pages for IPv4/IPv6 Policy and Explicit Proxy Policy
  - Add validation for "ssl-ssh-profile" when configuring UTM profiles
- Updated SSL/SSH Inspection list page
  - disabled delete menu on GUI for default ssl profiles
  - changed "Edit" menu to "View" menu for default ssl profiles
  - added implicit class (grayed) the default ssl profile entries
- Updated SSL/SSH Inspection edit dialog
  - disabled all the inputs for default ssl profiles except download/view trusted certificate links
  - changed button to "Return" for default ssl profiles to return the list page
- Updated Profile Group edit dialog
  - removed checkbox for "ssl-ssh-profile" option, make it always required.

#### CLI changes

1. `ssl-ssh-profile` default value is `certificate-inspection` when applicable in table `firewall.profile-group`, `firewall.policy`, `firewall.policy6`, `firewall.proxy-policy`
2. make default profiles "certificate-inspection", "deep-ssl-inspection" read only in table `firewall.ssl-ssh-profile`

### Botnet database changes (390756)

Starting in FortiOS 5.6, FortiGate units and FortiGuard Distribution Servers (FDS) will use object IDs IBDB and DBDB to download and update the Botnet database. Botnet protection will be part of the AntiVirus contract.

FortiOS 5.4 uses object IDs IRDB and BDDb.

## Fortinet Security Fabric audit check for endpoint vulnerability and unauthorized FAP and FSW (401462)

The new Security Fabric Audit feature allows for the display of endpoint vulnerability status in real-time. Users can see:

- FortiClient devices that have critical vulnerabilities detected.
- Discovered FortiSwitches that have not yet been authorized.
- Discovered FortiAPs that have not yet been authorized.

## Change to CLI commands for configuring custom Internet services (397029)

Custom internet services are no longer configured through use of the commands `config application internet-service` and `config application internet-service-custom` in the CLI.

These commands are replaced by `config firewall internet-service` and `config firewall internet-service-custom`.

### CLI Syntax - examples

```
config firewall internet-service 1245324
 set name "Fortinet-FortiGuard"
 set reputation 5
 set icon-id 140
 set offset 1602565
 config entry
 edit 1
 set protocol 6
 set port 443
 set ip-range-number 27
 set ip-number 80
 next
 edit 2
 set protocol 6
 set port 8890
 set ip-range-number 27
 set ip-number 80
 next
 edit 3
 set protocol 17
 set port 53
 set ip-range-number 18
 set ip-number 31
 next
 edit 4
 set protocol 17
 set port 8888
 set ip-range-number 18
 set ip-number 31
 next
 end
end

config firewall internet-service-custom
 edit "custom1"
 set comment "custom1"
```

```
config entry
 edit 1
 set protocol 6
 config port-range
 edit 1
 set start-port 30
 set end-port 33
 next
 end
 set dst "google-drive" "icloud"
 next
end
next
end
```

### Enable "sync-session-ttl" in "config ips global" CLI by default (399737)

`sync-session-ttl` is now set to enable by default in order to:

- enhance detection of P2P traffic. Efficient detection of P2P is important on hardware accelerated platforms
- ensure that IPS and the kernel use the same ttl
- ensure that IPS sessions time out sooner

### New diagnose command to delete avatars (388634)

Commands to delete avatars by FortiClient UID or avatar name have been added to the CLI.

the two following commands has been added to diagnose endpoint avatar:

- `diagnose endpoint avatar delete <ftcl_uid>`
- `diagnose endpoint avatar delete <ftcl_uid> <username>`

The attribute `delete` did not exist before. The values `<ftcl_uid>` and `<user_name>` describe a set of avatars. If only `<ftcl_uid>` is defined, all avatars belonging to this FortiClient UID that are not being used will be removed. If both values are defined, the avatar belonging to them will be removed unless they are being used in which case this call will cause an error to user.

### Fortinet bar option disabled in profile protocol options when VDOM is in flow-based inspection mode (384953)

In order to prevent the Fortinet Bar from being enabled and redirecting traffic to proxy (WAD) when a VDOM is in flow-based mode, the Fortinet Bar option is disabled in profile protocol options.

### SSL/SSH profile certificate handling changes (373835)

In order to support DSA and ECDSA key exchange (in addition to RSA) in SSL resign and replace mode, CLI commands for `deep-inspection` have changed. The `certname` command in `ssl-ssh-profile` has been removed.

To select from the list of available certificates in the system, use the CLI below.

```
edit deep-inspection
 set server-cert-mode re-sign
 set certname-{rsa | dsa | ecdsa}
```

## Restricting access to YouTube (replacement for the YouTube Education filter feature) (378277)

Previous versions of FortiOS supported YouTube for Schools (YTfS). As of July 1, 2016 this feature is no longer supported by YouTube. Instead you can use the information in the YouTube support article [Restrict YouTube content on your network or managed devices](#) to achieve the same result. FortiOS supports applying **Strict** or **Moderate** restrictions using HTTP headers as described in this article.

In FortiOS 5.6 with inspection mode set to proxy-based, in a Web Filter profile under **Search Engines** you can select **Restrict YouTube Access** and select either **Strict** or **Moderate**.

## Enhancements to IPS Signatures page (285543)

The IPS signatures list page now shows which IPS package is currently deployed. Users can also change their IPS package by linking directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

## DLP sensor GUI changes (307225)

The DLP sensor for file size has been corrected to indicate that the file size has to be greater than the number of KB entered. Previously, the GUI incorrectly showed that the files size could be greater than or equal to the number of KB entered.

## Web Filter profile page GUI updates (309012)

The GUI for the **Web Filter** security profile and **Web Profile Overrides** pages are changed.

### Web Filter profile page

- removed multilist for override user group and profile
- replaced FortiGuard categories actions icons with font icons
- added tooltip for **Allow users to override blocked categories** to explain the policy group dependency

### Web Profile Overrides page

- removed multilist of user, user group, original profile, new profile
- duplicate profile for new profile (for bug #284239)

## Web Filter Quota traffic can no longer be set to 0 (374380)

To fix a bug in older major release, the CLI has been changed so that minimum traffic quota does not allow 0 as an entry. The value entered must be in the range of 1 - 4,294,967,295; if 0 is entered, then an error message will be returned.

### CLI Commands:

```
config webfilter profile
 edit default
 config ftgd-wf
 config quota
 edit 1
 set type traffic
 set value {a number in the range of 1 - 4,294,967,295}
```

### Webcache-https and SSL deep inspection profile configuration changes (381101)

In older releases, the CLI blocked the configuration of the SSL deep inspection profile when webcache-https was enabled. This bug is fixed in FortiOS 5.6.0.

### FortiGate conserve mode changes (242562, 386503)

The following changes were made to rework **conserve mode** and facilitate its implementation:

- Implemented CLI commands to configure **extreme**, **red**, and **green** memory usage thresholds in percentages of total RAM. Memory used is the criteria for these thresholds, and set at 95% (extreme), 88% (red) and 82% (green).
- Removed structure `av_conserve_mode`, other changes in kernel to obtain and set memory usage thresholds from the kernel
- Added conserve mode diagnostic command `diag hardware sysinfo conserve`, which displays information about memory conserve mode.
- Fixed conserve mode logs in the kernel
- Added conserve mode stats to the proxy daemon through command `diag sys proxy stats all | grep conserve_mode`

### New custom IPS and Application Control Signatures list (280954)

You can now create IPS and Application control custom signatures by going to **Security Profiles > Custom Signatures**. From here you can create and edit all custom IPS and Application Control signatures.

### Default inspection mode set to flow-based (377392)

In FortiOS 5.6.0, the following changes were made to inspection mode:

- factory default sets the FortiGate to flow-based inspection with VDOM disabled
- whenever a VDOM is created, the default inspection mode is flow-based
- when in flow-based inspection mode, the Inspection Mode will not appear on the **Dashboard**; it will appear when in proxy-based inspection mode.

You must use the CLI to set the FortiGate to proxy-based inspection. To change the inspection mode back to flow-based inspection, you may use the GUI or the CLI.

```
config system settings
 edit <name_str>
 set inspection-mode {proxy | flow}
end
```

## Inside FortiOS: AntiVirus

AntiVirus uses a suite of integrated security technologies to provide against a variety of threats, including both known and unknown malicious codes (Malware), plus Advanced Targeted Attacks (ATA), also known as Advanced Persistent Threats (APT).

### Advanced Protection against Malware and APTs

Malware and Advanced Persistent Threats can cause significant damages to today's organizations. These malicious codes are commonly designed to steal valuable data, gain unauthorized access, or cause products to degrade. FortiOS's AntiVirus is an industry-proven anti-malware security solution with robust features and deployment options

FortiOS offers the unique ability to implement both Flow- and Proxy-based AV concurrently, depending on traffic type, users, and locations. Flow-based AV offers higher throughput performance while proxy-based solutions are useful in mitigating stealthy malicious codes. The AV detection capabilities are further enhanced with complementary security features and external sandbox integration.

By utilizing the unique Content Pattern Recognition Language (CPRL) built into the FortiASIC Content Processor, FortiOS is able to deliver high performance and low latency anti-malware capabilities. This real-time protection is backed by a team of worldwide researchers.

### Highlights

- Certification from multiple industries for best-in-class security and capacity with proven coverage and high performance.
- Multi-layered protection with extended AV components and external file analysis integration.
- Comprehensive remediation actions such as file quarantine and knowledge tools.

### Key Features & Benefits

|                                                                             |                                                                                                                 |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Robust feature set</b>                                                   | Allows the flexibility to deploy appropriate protection according to security needs and infrastructure designs. |
| <b>High performance utilizing FortiASIC and patented CPRL AV signatures</b> | Low latency and high capacity ensures that business applications are not affected while security is enforced.   |
| <b>Backed by FortiGuard Labs that deliver real-time protection</b>          | Critical digital assets are covered by continuous protection against latest threats.                            |

## Features

### Industry's Validated Protection

FortiOS anti-malware components and FortiGuard AV signatures periodically undergo numerous authoritative certifications. These independent certifications demonstrate that the solution offered is of the highest standard in performance and accuracy, ensuring organizations are truly protected.

Fortinet has been consistently ranked among the top vendors for Virus Bulletin's RAP (Reactive And Proactive) bimonthly tests. This test measures a product's detection rates over the freshest samples available, as well as samples not seen until after product databases are frozen, thus reflecting both the vendor's ability to handle the huge quantity of newly emerging malware and accurately detect previously unknown malware.

## Real Time Protection

The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content-level threats via the experienced FortiGuard global network is backed by over 200 researchers. With the release of FortiOS 5.6, botnet protection is part of the FortiGuard AntiVirus contract.

### FortiGuard AV service quick facts

- 95,000 malware programs neutralized per minute
- 1.8 Million new and updated AV definitions per week
- Hourly updates of the AV signature database
- 190 TB of threat samples till date

Organizations can also engage the FortiGuard Premier Signature Service, which provides enhanced virus detection and threat analysis support. This service offers submissions for custom AntiVirus signatures on a daily basis, offering prioritized support with guaranteed response times. With the release of FortiOS 5.6, botnet protection is part of the FortiGuard AntiVirus contract.

## Unique Proxy and Flow Based AV

FortiOS offers organizations the flexibility to select the most appropriate inspection method for different network sessions. This can be implemented by defining policies that match specific source objects (IP, IP ranges, users, and devices), destination objects, applications, and schedules with different AV profiles.

Flow-based AV relies on IPS technology where packets are inspected in real-time and matched against the AV signature database. It offers lower latency and higher throughput than Proxy-based AV. Flow-based AV is recommended for inspecting traffic that requires spontaneous user experience or when serving as an additional AV protection layer.

FortiOS's Proxy-based AV offers the most secure AV protection as it's able to inspect more protocols and provides replacement messages on wider range of applications.

## AV Acceleration with Content Processor

The FortiASICS Content Processor (CP) accelerates content processing traditionally performed completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

## Proactive Protection using Patented CPRL

Compact Pattern Recognition Language (CPRL) is a patented and proprietary programming language that allows for further inspection of common patterns to not only protect against threats and their variants but also to predict tomorrow's zero-day malware. It allows FortiGuard analysts to describe entire families of malware with a single program, instead of the traditional signature-based "one signature, one variant" model used by other vendors. With fewer signatures to match, throughput performance and latency naturally improve.

## Intelligent Behavioral Evaluation

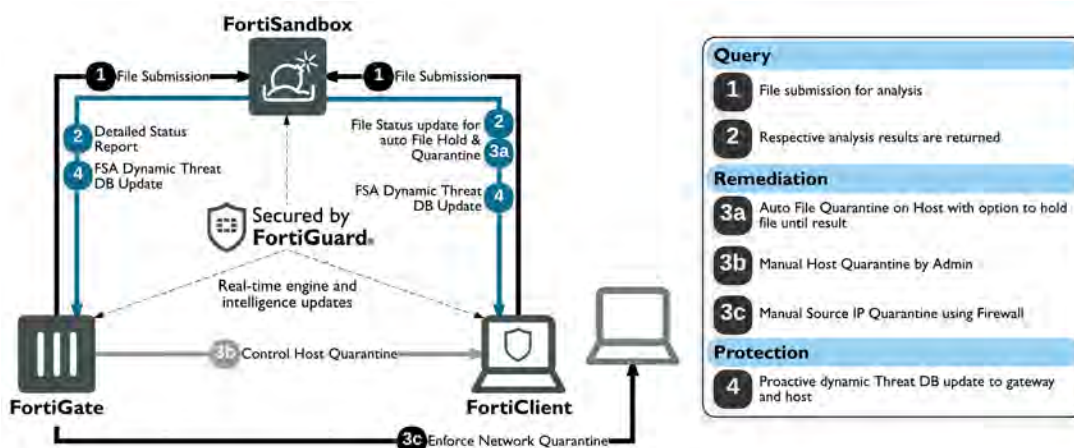

Signature-based security alone is no longer sufficient; it is now critical to understand how devices on your network are behaving. Threat Weight scoring provides a cumulative security ranking of each client device on your network based on a range of behaviors. It provides specific, actionable information that helps identify compromised systems and potential zero-day attacks in real-time.

This unique system attaches predefined scores to various malicious network activities discovered by IPS, application control, URL filtering, etc., to determine the top suspicious users. Administrator can then further inspect these users to undercover unknown threats or APTs via FortiView.

## External File Analysis Integration

FortiOS offers organizations the ability to adopt robust ATP (Advanced Threat Protection) framework that reaches mobile users and branch offices, detecting and preventing advanced attacks that may bypass traditional defenses by examining files from various vectors, including encrypted files. To detect unknown threats, zero-day, and targeted attacks, the FortiGate can engage external resources to perform additional file analysis. Files can be submitted to an on-premise appliance (FortiSandbox) or cloud-based service (FortiSandbox Cloud) after both proxy-based and flow-based AV processing.

It is also possible to configure the FortiGate to automatically receive dynamic signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list. In addition, if the organization deploys integrated endpoint control with FortiClient, an administrator can instruct an infected terminal to self-quarantine.

## **File Filtering**

File filtering using data leak prevention (DLP) on the FortiGate offers an effective way to stop unwanted file transmission instantly. Administrators may implement granular file controls by defining protection profiles using filenames or nearly 50 different file types over mail, web, and file download protocols.

## **File Quarantine**

FortiOS offers sophisticated file quarantine capabilities that allow organizations to archive suspicious or blocked files for further examination or to release false positives.

## **Anti-bot**

Organizations may prevent, uncover, and block botnet activities using FortiOS Anti-Bot traffic pattern detection and domain and IP reputation services supplied in real-time by FortiGuard threat experts.

## **User Notification**

User notifications are helpful in reducing administration and support burdens, as well as providing user education. FortiOS is able to automatically replace blocked attachments and downloads with detailed information sent to E-mail, FTP, or web users.

## **Monitoring, Logging, and Reporting**

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView widgets provide useful analysis data with detailed and contextual session information, which can be filtered, ranked, and further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

FortiOS also offers robust in-built E-mail and SMS alert systems, as well as integration with external threat management systems using SNMP and standard-based Syslogs.

# **Inside FortiOS: Application Control**

Application control technologies detect and take action against network traffic based on the application that generated the traffic. Application control uses protocol decoders with signatures that analyze network traffic to detect application traffic, even if the traffic uses nonstandard ports or protocols.

## **Enhance Control and Network Visibility**

Controlling and monitoring applications on a network can seem like a daunting task due to the wide range of available applications. It is no longer an option to simply block or allow TCP and/or UDP ports since most applications do not map to individual ports. For example, controlling traffic on an HTTP or HTTPS port is futile against complex social networking sites and cloud applications.

FortiOS leverages its massive application database to identify applications and their activities while still providing a suitable and sufficient user experience, thanks to FortiASIC Content Processors (CPs), which boost CPU performance. Organizations can adopt more granular control, such as allowing logins but not chatting over selected sites. Traffic shaping may also be applied to the application traffic that is allowed. After applying control measures, continuous monitoring ensures that the measures are effective and allow for changes in application traffic patterns to be managed.

## Highlights

- Superior performance using the unique FortiASIC Content Processor that offloads heavy computation from the CPU.
- Flexible implementation with robust deployment modes and granular controls.
- Excellent visibility and management tools that help administrators improve security.
- Application control is a standard part of any FortiCare support contract and the database for application control signatures is separate from the IPS database. You don't require a FortiGuard IPS subscription to access the database.

To receive updates to the Application Control signature database, you must have a valid FortiCare support contract.

- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).
- Ability to configure application control by adding individual applications or application categories to security policies when operating in flow-based inspection and NGFW policy-based mode.

## Key Features & Benefits

|                                                                              |                                                                                                                 |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Identifies and controls application traffic</b>                           | Allows organization to strengthen security policies by controlling evasive application communications.          |
| <b>Leverages FortiGate's hardware acceleration and software optimization</b> | Offers more security without compromising performance.                                                          |
| <b>Granular control and integration with other FortiOS capabilities</b>      | Provides administrators the ability to implement the most appropriate configuration for any given organization. |

## Features

### NSS Labs “Recommend” Rating for Next Generation Firewall

Fortinet's entry into the NSS Labs Next Generation Firewall Group Test in 2013, 2014 and 2016 received the “Recommend” rating, placing it as one of the top performing systems. NSS Labs uses respectable real-world testing methodologies to measure Next Generation Firewall protection and performance, including application control.

### Superior performance with Unique Hardware Architecture

Unlike a traditional security gateway, which relies heavily on CPUs for packet inspection, the FortiGate's unique hardware architecture allows FortiOS to automatically utilize appropriate hardware components to achieve optimal performance. This prevents the CPU from becoming a bottleneck as it performs various functions concurrently.

In support of application control, the Content Processor (CP) is a specialized ASIC chip that handles demanding cryptographic computation for SSL inspection and intensive signature matching. By offloading these processes

from the CPU, the FortiGate is able to minimize performance degradation when administrators opt for greater security.

## Robust Deployment Modes

FortiOS supports a wide array of network protocols and operating modes, allowing administrators to deploy the most appropriate security for their unique IT infrastructure. FortiOS also supports a variety of routing and switching protocols.

The FortiGate is able to operate in inline route and transparent mode. It can also operate in offline sniffer mode for passive monitoring of user activities. These different operating modes run concurrently by using virtual systems.

## Protection at the Edge

With today's BYOD and mobile workforce environment, it is no longer wise to deploy control just at the Internet gateway. Through Fortinet Security Fabric, FortiOS unique wireless and switch controller feature allows organizations to implement better visibility and protection closer to internal devices. Moreover, with FortiClient, administrators can also apply similar policies when mobile users are outside of the protected networks.

## Advanced Application Detection and Control

By relying on the FortiOS 3rd Generation IPS engine, the FortiGate is able to inspect many of today's encrypted and evasive traffic, as well as traffic running on new technologies, such as SPDY protocol. The inspection can be applied to both network and IPsec/SSL VPN traffic.

An application and its specific activity are identified using FortiGuard's Application Control database of over 2,500 distinct signatures. These signatures are crafted by researchers across the globe to include applications that may be unique to platforms, regions, and/or languages. It also offers specific application activity identification, such as a Facebook posting or Dropbox file sync. The database is kept up to date via scheduled or manual downloads.

The application database is classified into 20 intuitive categories for ease of use. Administrators may also create specific application overrides that differ from the category settings. These specific applications can be filtered and selected by type of behavior, risk levels, technology type, application vendor and popularity.

Administrators may also apply advanced controls, such as setting up session TTLs for specific applications using CLI commands.

## Traffic Shaping

Organizations may better utilize bandwidth and protect critical applications by enforcing granular application usage with traffic shaping. Administrators can create various traffic shaping profiles by defining traffic priority and maximum or guaranteed bandwidth. These profiles can then be assigned to targeted applications.

## User Notification

User education is central to an effective security implementation. In response to this, FortiOS lets you provide user notification when blocking an unauthorized application. The notification appears as an HTML block page for web-based applications.

Advanced notification is possible by implementing Fortinet's browser-embedded frame. And when "off-net" users are denied access, notifications appear via FortiClient's notification pop-ups.

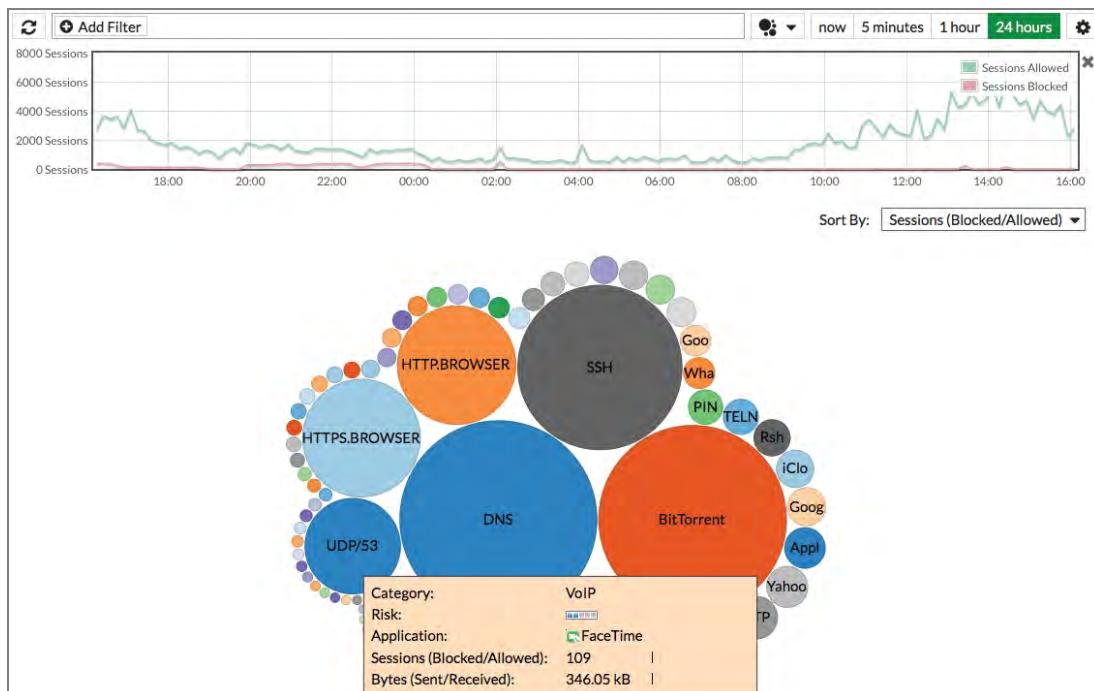

## Deep Inspection for Cloud Applications

The prevalence of cloud applications like Dropbox poses a security challenge to today's organizations. Using FortiOS's deep inspection for popular cloud applications, administrators gain deep and useful insights, via FortiView and logs, into activities associated with these applications, such as user IDs, cloud actions, file names, and file sizes. For popular video sites, FortiOS will also be able to track video files viewed.

## SSL Inspection for Encrypted Traffic

SSL (Secure Sockets Layer) is a popular encryption standard used to protect Internet traffic but may also be used to evade traditional inspection. FortiOS enables organizations to adopt effective application control even when traffic is encrypted.

Unique hardware components and software optimizations can decrypt traffic with minimal performance impact. The inspection can easily omit sensitive communications, such as financial transaction (thereby complying with privacy policies), or bypass applications that forbid SSL inspection by using granular policy settings.

## Monitoring, Logging, and Reporting

FortiOS empowers organization to implement security best practices that require continuous examination of threat statuses and the ability to adapt to new requirements.

The FortiView widgets provide useful analyses with detailed and contextual session information that can be filtered, ranked, and further inspected. For example, an administrator can instantly query the top applications that are currently consuming bandwidth and drill down to identify their users and help decide if such activities should be blocked.

Network, threat, and system events activities can be archived via syslogs. In turn, these logs can generate useful trending and overview reports.

Lastly, the FortiOS offers robust in-built email and SMS alert systems. Meanwhile, integration with external threat management systems can be achieved with SNMP and standard-based syslogs.

## Inside FortiOS: Intrusion Prevention System (IPS)

Intrusion Prevention System (IPS) technology protects your network from cybercriminal attacks by actively seeking and blocking external threats before they can reach potentially vulnerable network devices.

## World Class Next Generation IPS Capabilities

Today, sophisticated and high volume attacks are the challenges that every organization must recognize. These attacks are evolving, infiltrating ever-increasing vectors and complex network environments. The result is an urgent need for network protection while maintaining the ability to efficiently provide demanding services and applications.

FortiOS's IPS functionality is an industry-proven network security solution that scales up to over 200 Gbps of in-line protection. Powered by purpose-built hardware and FortiASICs, FortiOS is able to achieve attractive TCO while meeting performance requirements. IPS is easy to set up, yet offers feature-rich capabilities, with contextual visibility and coverage. It is kept up-to-date by research teams that work 24 hours a day worldwide, in order to detect and deter the latest known threats as well as zero-day attacks.

## Highlights

- Validated best-in-class security and capacity with proven coverage and high performance.
- Comprehensive protection provided by a signatures-based IPS engine, protocol anomaly scanning, and DDOS mitigation.
- Flexible deployment options and actionable implementations for a wide array of network integration and operation requirements.

## Key Features & Benefits

|                                                                    |                                                                                                                                                                                       |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>High Performance IPS, powered by FortiASIC</b>                  | Low latency and high capacity ensure business applications are not affected while security is enforced.                                                                               |
| <b>Best-in-class security with superior coverage</b>               | Protects critical digital resources from both internal exploits and external cybercriminals, even if sophisticated attacks are crafted.                                               |
| <b>Backed by FortiGuard Labs that deliver real-time protection</b> | Maintains up-to-date and proactive protection against latest known threats and newly discovered hacking techniques while allowing time for organizations to patch vulnerable systems. |

## Features

### Tested and Proven Protection

Not only have FortiGates been deployed in some of the largest enterprises in the world since 2002, FortiOS IPS components and FortiGuard IPS signatures are periodically tested and certified by well-known external labs. For example, Fortinet's FortiGate 3000D earned the highest ratings for Security Effectiveness, blocking 99.9 percent of exploits in the recent NSS Labs DCIPS test. These independent certifications ensure that solutions delivered to customers are of the highest standards in performance, coverage, and accuracy.

### Real-Time & Zero-day Protection

The FortiGuard Intrusion Prevention Service (IPS) provides customers with the latest defenses against stealthy network-level threats through a constantly updated database of known threats and behavior-based signatures.

#### FortiGuard IPS service quick facts

- Over 10,000 signatures consisting of 18,000 rules
- Approximately 470,000 network intrusion attempts resisted per minute
- About 1,000 rules are updated or added per week
- Over 300 Zero-day vulnerabilities discovered to date

This update service is backed by a team of threat experts and a close relationship with major application vendors. The best-in-class team also uncovers significant zero-day vulnerabilities continuously, providing FortiGate units with advanced protection ahead of vendor patches.

### Uncompromised Performance

The FortiASIC Content Processor (CP) accelerates content processing, which is traditionally done completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

### Protocol Decoders and Anomaly Detection

Protocol decoders are required to assemble the packets and detect suspicious, nonconforming sessions that resemble known attacks or are non-compliant to RFC or standard implementation.

FortiOS offers one of the most comprehensive arrays of protocol decoders in the industry, providing customers with significantly wide coverage in all kinds of environments.

### **Pattern & Rate-Based Signatures**

The pattern signature matching technique is essential in IPS implementation due to its high level of precision and accuracy. FortiOS offers administrators robust pattern signature selection using filters based on severity, target, operating system, application, and protocol. Each of the 10,000+ signatures has a direct link to its detailed entry on the threat encyclopedia and CVE-ID references. After selection, administrators are able to assign associated actions such as monitoring, blocking, or resetting the session.

Rate-based IPS signatures protect networks against application based DoS and brute force attacks. Administrators can configure nearly 30 rate-based IPS signatures and tune them to their needs. Threshold (incidents per minute) and an action to take when the threshold is reached can be assigned to each signature. If the action is set to block, then a timeout period can be set so that the block is removed after a specified duration.

### **DoS and DDoS Mitigation**

DoS policies can help protect against DDoS attacks that aim to overwhelm server resources. In FortiOS, the DoS scans precede the policy engine at the incoming interfaces, thus eliminating unnecessary sessions from the firewall process and state table entry during a surge of attack traffic. This helps to safeguard the firewall from overloading and allows it to perform optimally.

FortiOS DoS policies can be configured to detect and block floodings, port scans, and sweeps. Administrators can set baselines for the amount of concurrent sessions from sources or to destinations. The settings utilize thresholds and can be applied to UDP, TCP, ICMP, IP, and SCTP.

Network interfaces associated with a port attached to a Network Processor (NP) can be configured to offload anomaly checking, further offloading the CPU for greater performance. Some of the anomaly traffic dropped includes LAND attacks, IP protocol with malformed options, and WinNukes.

### **Quarantine Attacks**

FortiOS offers sophisticated automatic attack quarantine capabilities which allow organizations to proactively prevent further attacks from known attackers over a predefined duration. Quarantining by duration can be used to protect potentially vulnerable servers until more permanent defense.

### **Packet Logging**

Administrators may choose to automatically perform IPS packet logging, which saves packets for detailed analysis when an IPS signature is matched. Saved packets can be viewed and analyzed on the FortiGate unit or by using third-party analysis tools. Packet logging is also useful in determining false positives.

### **Custom Signatures**

Custom IPS signatures can be created to further extend protection. For example, you can use custom IPS signatures to protect unusual or specialized applications, or even custom platforms from known and unknown attacks.

Organizations may use FortiConverter to easily convert Snort signatures for FortiOS use.

| Enable                              | Signature                            | Threshold | Duration (seconds) | Track By | Action                                   | Block Duration (minutes) |
|-------------------------------------|--------------------------------------|-----------|--------------------|----------|------------------------------------------|--------------------------|
| <input checked="" type="checkbox"/> | Apache.HTTP.Server.DoS               | 200       | 1                  | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | Digium.Asterisk.File.Descriptor.DoS  | 20        | 1                  | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | Digium.Asterisk.IAX2.Call.Number.DoS | 275       | 1                  | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | DotNetNuke.Padding.Oracle.Attack     | 1000      | 5                  | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | FTP.Login.Brute.Force                | 200       | 10                 | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | FreeBSD.TCP.Reassembly.DoS           | 10        | 2                  | Any      | <span style="color: red;">⛔</span> Block | None                     |
| <input checked="" type="checkbox"/> | GlassFish.Login.Brute.Force          | 200       | 10                 | Any      | <span style="color: red;">⛔</span> Block | None                     |

[Apply](#)

## Resistant Against Evasions

Evasion techniques attempt to fool the protocol decoders in IPS products by crafting exotic network streams that would not be handled or reconstructed by the decoders, yet still be valid enough for the target recipient to process. Robust IPS engine is capable of handling both common evasions and sophisticated AETs (Advanced Evasion Techniques) deployed by hackers such as IP Packet Fragmentation, TCP Stream Segmentation, RPC Fragmentation, URL & HTML Obfuscation, and other protocol specific evasion techniques.

## Intrusion Detection Mode

In out-of-band sniffer mode (or one-arm IPS mode), IPS operates as an Intrusion Detection System (IDS), detecting attacks and reporting them but not taking any action against them. In sniffer mode, the FortiGate unit does not process network traffic and instead is connected to a spanning or mirrored switch port, or a network tap. If an attack is detected, log messages can be recorded and alerts sent to system administrators.

## Traffic Bypass

Since most IPS deployments are in transparent inline mode, active traffic bypass is often desired until normal operation of the device resumes. Some FortiGates offer inbuilt active bypass interfaces while others may use external bypass devices such as the FortiBridge. Administrators are also offered with software fail-open option to tackle instances where the IPS engine fails.

## Monitoring, Logging, and Reporting

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView query widgets provide useful analysis data

with detailed and contextual session information, which can be filtered, ranked, and further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

## Inside FortiOS: Web Filtering

A Web Filtering solution is designed to restrict or control the content a reader is authorized to access, delivered over the Internet via the Web browser. It may be used to improve security, prevent objectionable activities, and increase productive within an organization.

### Intelligent and Effective Content Control

Web-based threats such as Phishing, drive-by Malware sites, and Botnets are more sophisticated and scrutinized than ever, and as well as increasingly difficult to control due to the rise of mobility in the workplace, even more difficult for you to control. The Web has become the preferred medium of choice for hackers and thieves looking for new ways to disrupt services, steal information, and perform malicious activities for financial gain. In addition, employees who visit websites containing objectionable content can expose your organization to civil or criminal liability.

FortiOS Web Filtering solution utilizes three main components of the web filtering function: the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service. These functions integrate with each other to provide maximum control over what the Internet user can view as well as protection to the network from many Internet content threats. Web Content Filtering blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic by independent real-world tests.

### Highlights

- Comprehensive and advanced Web Filtering features Safe Search and user override options.
- FortiGuard Web Filtering Services with superior coverage of over 250 million rated websites.
- Integration with other FortiOS components, such as User Identification for flexible and secured implementation.
- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).
- Ability to configure web filtering by adding URL categories to security policies when operating in flow-based inspection and NGFW policy-based mode. You can set the action to accept or deny to allow or block the applications.

### Key Features & Benefits

|                                                                |                                                                                                                       |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Cloud-based Rating Database</b>                             | Real-time website category rating provides accurate content control.                                                  |
| <b>Wide choice of web filtering technologies</b>               | Various web filtering technology options are available to provide each organization the most suitable implementation. |
| <b>Integrated with other security and networking functions</b> | Allows organizations to simplified networks and reduce TCO.                                                           |

## Features

### Cloud-based Rating System

Fortinet is a pioneer in cloud-based rating systems for web filtering. FortiOS provides an innovative approach to HTTP and HTTPS web filtering technology by combining the advantages of a cloud-based service offering with layered response caching. The multiple FortiGuard data centers around the world hold the entire categorized URL database and receive rating requests from FortiGate units triggered by browser-based URL requests. FortiGuard responds to these rating requests with the categories stored for specific URLs, the requesting FortiGate unit then uses its own local profile configuration to determine what action is appropriate to the category, such as: blocking, monitoring, allowing the page, displaying a warning, or requiring authentication to view the page.

Rating responses are also cached directly in FortiGate unit memory so that ratings for frequently used sites can be retrieved directly from the cache, reducing the number of requests to the FortiGuard network. Caching URLs in memory makes URL lookups almost instantaneous while only using a very small amount of system memory.

An appropriately licensed FortiManager appliance can be synchronized to the FortiGuard network and as such can be used in the same way to as the FortiGuard network for managed FortiGate devices. This can further reduce any latency associated with the round trip time for individual rating requests while at the same time ensuring complete database coverage. Consider the combination of a LAN attached FortiGate cluster and FortiManager combination with the potential to handle tens of thousands of requests per second.

### Superior Coverage

FortiGuard Web Filter ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. This service currently rates more than 250 million sites covering billions of URLs with each site able to be rated in multiple categories. The FortiGuard database provides a truly international service with support for 70 languages.

### Extensive and Flexible Categorization

Rated URLs are assigned into one of the 98 categories (including 20 user defined ones) which administrators can then easily manage and control. Administrators can configure and populate local categories or place specific URLs in existing categories should the FortiGuard rating not be in agreement with an organization's policies and practices.

### Rating Override

At times, administrators may have to allow approved people to access what they need during periods when an exception to the normal rules is required, while still having enough control that the organization's web usage policies are not compromised. FortiOS can provide such setup by using alternate profiles.

### Protection against Malicious URLs

The malicious URL database contains all malicious URLs active in the last month and is organized as one of the categories. With Fortinet Security Fabric, customers can further their protection by having the FortiSandbox add newly discovered URLs to a dynamic URL filter, thus blocking files from being downloaded again from that URL.

## Inspection Modes

FortiOS web filtering can operate in different modes: proxy-based and flow-based inspection modes and DNS filtering. Each mode has strengths and weaknesses and all three can be active at the same time on different traffic streams.

**Proxy-based** web filtering uses a proxy to assemble and analyze web content as it passes through the FortiGate unit. If a page is blocked the proxy can replace the blocked page with a customizable web page informing users that the page is blocked. Proxy-based web filtering is the most feature-rich mode, supporting many advanced filters including web content filtering that analyzes web page content according to your custom requirements, Java applet filtering, and blocking invalid URLs.

**Flow-based** web filtering uses the FortiOS IPS engine to filter web content packets as they pass through the FortiGate unit without any buffering. Flow-based inspection does not use a proxy, so inspected packets are not proxied and altered by the FortiGate unit. Flow-based inspection does not support as many advanced features as proxy-based web filtering.

To control your FortiGate's security profile inspection mode in FortiOS 5.6, you can select **Flow** or **Proxy Inspection Mode** from **System > Settings**. Having control over flow and proxy mode is helpful if you want to ensure that only flow inspection mode is used.

In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Some implementations, however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

Two new policy modes are available in FortiOS 5.6.

- NGFW mode simplifies applying application control and web filtering to traffic by allowing you to add applications and web filtering profiles directly to policies. This is used in conjunction with flow-based inspection.
- Transparent proxy allows you to apply web authentication to HTTP traffic without using the explicit proxy.

**DNS web filtering** employs DNS lookups to the FortiGuard DNS service to get web page ratings. Filtering is done as part of the DNS lookup and web pages can be blocked or redirected to a web filter block page before the HTTP session starts. As a result, it is lightweight in terms of resource usage although it only supports a limited number of advanced features.

## Usage Quota

Administrators can set a daily timed access quota by category or category group. Quotas allow access for a specified length of time or traffic volume, calculated separately for each user.

## Safe Search

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch on the FortiGate for the supported search sites can better enforce its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature.

## Restrict YouTube Access

In FortiOS 5.6 with inspection mode set to proxy-based, you can set Strict or Moderate access to YouTube in a Web Filter profile.

## Manual URL and Content Filter

FortiOS web filtering offers specific URL filtering by standard, wildcard, and regular expression definition, as well as content filtering by pattern type and language.

## Advanced web filter configurations

FortiOS rich feature set includes ability to implement a number of enterprise features such as:

- Block HTTP redirects by rating, invalid URLs, HTTP POST actions, and Web resume download
- Cookie, Java applet, and ActiveX filter
- Rate Images by URL and URLs by domain and IP address
- Restrict Google account usage to specific domains

## Proxy Avoidance Preventions

FortiGate is able to improve the effectiveness of the web filtering by preventing users from evading the security implementation. Organizations can use its multiple integrated technologies including proxy site URL, proxy application control, and IPS proxy behavior blocking.

## User and Device Awareness

Most networks in today's organizations are connected with both corporate and personal mobile devices. User and device awareness provides the option to configure intelligent policies that can effectively enforce security.

To tackle the prevalence of BYOD environments, administrators are able to configure web content access policies with sources defined by IPs, users, and devices, either combined or selectively.

## External URL Filtering support

In instances where customers have large, existing, deployed implementations of a specific URL filtering solution but replace their legacy firewalls with a FortiGate family, they can still retain their web filtering infrastructure since FortiOS supports both ICAP and WISP.

## **Monitoring, Logging, and Reporting**

FortiOS empowers an organization to implement security best practices that require continuous monitoring of threats, allowing the organization to adapt to new requirements.

The FortiView dashboards display useful analysis data with detailed and contextual session information, which can be filtered and ranked, with drilldown options also available. This information, including system events activities and administration audit trails, can also be archived via logs.

FortiOS logs all the types of traffic that can connect to or terminate at the FortiGate unit. In turn, these logs can generate useful trending and overview reports.

## Security Profiles overview

The FortiGate line combines a number of security features to protect your network from threats. As a whole, these features, when included in a single Fortinet security appliance, are referred to as Security Profiles.

This overview addresses the following topics:

- [Traffic inspection](#)
- [Content inspection and filtering](#)
- [Security Profiles components](#)
- [Security Profiles/lists/sensors](#)

Firewall policies limit access, and while this and similar features are a vital part of securing your network, they are not covered in this discussion of Security Profiles.

FortiOS 5.4 no longer supports FortiClient 5.0.

FortiOS 5.4.1 supports only FortiClient 5.4.1. Be sure to upgrade managed FortiClients before upgrading the FortiGate to 5.4.1.

FortiOS 5.2 can support FortiClient 5.0, but only if the FortiGate upgraded to FortiOS 5.2. Customers need to purchase a FortiClient 5.4 subscription-based FortiClient license.

---

## Traffic inspection

When the FortiGate unit examines network traffic one packet at a time for IPS signatures, it is performing traffic analysis. This is unlike content analysis where the traffic is buffered until files, email messages, web pages, and other files are assembled and examined as a whole.

DoS policies use traffic analysis by keeping track of the type and quantity of packets, as well as their source and destination addresses.

Application control uses traffic analysis to determine which application generated the packet.

Although traffic inspection doesn't involve taking packets and assembling files they are carrying, the packets themselves can be split into fragments as they pass from network to network. These fragments are reassembled by the FortiGate unit before examination.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against content threats.

### IPS signatures

IPS signatures can detect malicious network traffic. For example, the Code Red worm attacked a vulnerability in the Microsoft IIS web server. Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions.

## IPS recommendations

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive new IPS signatures as soon as they are available.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to **Block**.
- You can view these signatures by going to **Security Profiles > Intrusion Prevention** and selecting the **[View IPS Signatures]** link in the right-hand corner of the window.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to **Block**.

## Suspicious traffic attributes

Network traffic itself can be used as an attack vector or a means to probe a network before an attack. For example, SYN and FIN flags should never appear together in the same TCP packet. The SYN flag is used to initiate a TCP session while the FIN flag indicates the end of data transmission at the end of a TCP session.

The FortiGate unit has IPS signatures that recognize abnormal and suspicious traffic attributes. The SYN/FIN combination is one of the suspicious flag combinations detected in TCP traffic by the `TCP . BAD . FLAGS` signature.

The signatures that are created specifically to examine traffic options and settings, begin with the name of the traffic type they are associated with. For example, signatures created to examine TCP traffic have signature names starting with TCP.

## Application control

While applications can often be blocked by the ports they use, application control allows convenient management of all supported applications, including those that do not use set ports.

### Application control recommendations

- Some applications behave in an unusual manner in regards to application control. For more information, see [Application considerations on page 2864](#).
- By default, application control allows the applications not specified in the application control list. For high security networks, you may want to change this behavior so that only the explicitly allowed applications are permitted.

## SSL/SSH inspection

Regular web filtering can be circumvented by using `https://` instead of `http://`. By enabling this feature, the FortiGate can filter traffic that is using the HTTPS protocol. This sort of analysis is some times referred to as deep scanning.

Deep Inspection works along the following lines: If your FortiGate unit has the correct chipset it will be able to scan SSL encrypted traffic in the same way that regular traffic can be scanned. The FortiGate firewall will essentially receive the traffic on behalf of the client and open up the encrypted traffic. Once it is finished it re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. By enabling this feature, it allows the FortiGate firewall to filter on traffic that is using the SSL encrypted protocol.

The encrypted protocols that can be inspected are:

- HTTPS
- SMTPS
- POP3S
- IMAPS
- FTPS

Before the invention of SSL inspection, scanning regular web traffic can be circumvented by using the prefix `https://` instead of `http://` in the URL. SSL inspection prevents this circumvention. However, because when the encrypted traffic is decrypted it has to be re-encrypted with the FortiGate's certificate rather than the original certificate it can cause errors because the name on the certificate does not match the name on the web site.

At one point deep inspection was something that was either turned on or off. Now individual deep inspection profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic.
- Configure which SSL protocols will be inspected.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites will be exempt from SSL inspection
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not SSH traffic will be inspected.

## Web Rating Overrides

This feature allows you to override the FortiGuard Web Filtering. This option allows users to change the rating for a website and control access to the site without affecting the rest of the sites in the original category. More information can be found in [Overriding FortiGuard website categorization](#).

## Web Profile Overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. See the section on [Web Profile Overrides](#) for more information.

## Content inspection and filtering

When the FortiGate unit buffers the packets containing files, email messages, web pages, and other similar files for reassembly before examining them, it is performing content inspection. Traffic inspection, on the other hand, is accomplished by the FortiGate unit examining individual packets of network traffic as they are received.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against threats to content. Be sure to understand the effects of the changes before using the suggestions.

## AntiVirus

The FortiGate antivirus scanner can detect viruses and other malicious payloads used to infect machines. The FortiGate unit performs deep content inspection. To prevent attempts to disguise viruses, the antivirus scanner will reassemble fragmented files and uncompress content that has been compressed. Patented Compact Pattern Recognition Language (CPRL) allows further inspection for common patterns, increasing detection rates of virus variations in the future.

## AntiVirus recommendations

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure that new antivirus signatures are loaded onto your FortiGate as soon as they are available.
- Enable the Extended Virus Database if your FortiGate unit supports it.
- Examine antivirus logs periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.
- To conserve system resources, avoid scanning email messages twice. Scan messages as they enter and leave your network or when clients send and retrieve them, rather than both.
- Enable **Treat Windows Executables in Email Attachments as Viruses** if you are concerned about incoming '.exe' files.

## FortiGuard Web Filtering

The web is the most popular part of the Internet and, as a consequence, virtually every computer connected to the Internet is able to communicate using port 80, HTTP. Botnet communications take advantage of this open port and use it to communicate with infected computers. FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

### FortiGuard Web Filtering recommendations

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous.
- In the Anti-Spam profile, enable **Spam Detection and Filtering** and then enable **IP Address Check**. Many IP addresses used in spam messages lead to malicious sites; checking them will protect your users and your network.

## DNS Filter

### DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

The following filtering options can be configured in a DNS Filter security profile:

## Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing; you must have an active FortiGuard web filtering license to use this feature. You can view the botnet lists by going to **System > FortiGuard > Botnet IPs** and **System > FortiGuard > Botnet Domains**.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**. When you do this in FortiOS 5.4.1, you can open a definitions window by clicking on "botnet package."

## Static URL filter

The DNS static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

## Anti-Spam

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine. The FortiGate email filter can detect harmful spam and mark it, alerting the user to the potential danger.

### Anti-Spam filter recommendations

- Subscribe to the FortiGuard Anti-Spam Filtering service.
- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint scanning for protection against threats that get into your network.

## Data Leak Prevention

Most security features on the FortiGate unit are designed to keep unwanted traffic out of your network while Data Leak Prevention (DLP) can help you keep sensitive information from leaving your network. For example, credit card numbers and social security numbers can be detected by DLP sensors.

### DLP recommendations

- Rules related to HTTP posts can be created, but if the requirement is to block all HTTP posts, a better solution is to use application control or the **HTTP POST Action** option in the web filter profile.
- While DLP can detect sensitive data, it is more efficient to block unnecessary communication channels than to use DLP to examine it. If you don't use instant messaging or peer-to-peer communication in your organization, for example, use application control to block them entirely.

## Security Profiles components

Below is a brief description of the security profiles and their features.

### AntiVirus

Your FortiGate unit stores a virus signature database that can identify more than 15,000 individual viruses. FortiGate models that support additional virus databases are able to identify hundreds of thousands of viruses. With a FortiGuard AntiVirus subscription, the signature databases are updated whenever a new threat is discovered.

AntiVirus also includes file filtering. When you specify files by type or by file name, the FortiGate unit will block the matching files from reaching your users.

FortiGate units with a hard drive or configured to use a FortiAnalyzer unit can store infected and blocked files for that you can examine later.

### Web Filter

Web filtering includes a number of features you can use to protect or limit your users' activity on the web.

FortiGuard Web Filtering is a subscription service that allows you to limit access to web sites. More than 60 million web sites and two billion web pages are rated by category. You can choose to allow or block each of the 77 categories.

URL filtering can block your network users from access to URLs that you specify.

Web content filtering can restrict access to web pages based on words and phrases appearing on the web page itself. You can build lists of words and phrases, each with a score. When a web content list is selected in a web filter profile, you can specify a threshold. If a user attempts to load a web page and the score of the words on the page exceeds the threshold, the web page is blocked.

### DNS Filter

The FortiGate will inspect DNS traffic to any DNS server, so long as the policy has DNS inspection enabled. The FortiGate will intercept DNS requests, regardless of the destination IP, and redirect it to the FortiGuard Secure DNS server – this is separate from the FortiGuard DNS server.

The Secure DNS server will resolve and rate the FQDN and send a DNS response which includes both IP and rating of the FQDN back to the FortiGate, where it will handle the DNS response according to the DNS filter profile.

### Application Control

Although you can block the use of some applications by blocking the ports they use for communications, many applications do not use standard ports to communicate. Application control can detect the network traffic of more than 1,000 applications, improving your control over application communication.

### Cloud Access Security Inspection (CASI)

This feature introduced in FortiOS 5.4 is now merged with Application Control. See the "[Cloud Access Security Inspection \(CASI\)](#)" on page 2860 discussion under Application Control for more information on this feature.

## Intrusion Protection

The FortiGate Intrusion Protection System (IPS) protects your network against hacking and other attempts to exploit vulnerabilities of your systems. More than 3,000 signatures are able to detect exploits against various operating systems, host types, protocols, and applications. These exploits can be stopped before they reach your internal network.

You can also write custom signatures tailored to your network.

## Anti-Spam

FortiGuard Anti-Spam is a subscription service that includes an IP address black list, a URL black list, and an email checksum database. These resources are updated whenever new spam messages are received, so you do not need to maintain any lists or databases to ensure accurate spam detection.

You can use your own IP address lists and email address lists to allow or deny addresses, based on your own needs and circumstances.

## Data Leak Prevention

Data Leak Prevention (DLP) allows you to define the format of sensitive data. The FortiGate unit can then monitor network traffic and stop sensitive information from leaving your network. Rules for U.S. social security numbers, Canadian social insurance numbers, as well as Visa, Mastercard, and American Express card numbers are included.

## VoIP

The Session Initiation Protocol (SIP) is an IETF application layer signaling protocol used for establishing, conducting, and terminating multi-user multimedia sessions over TCP/IP networks using any media. SIP is often used for Voice over IP (VoIP) calls but can be used for establishing streaming communication between end points.

For more information, see [VoIP Solutions: SIP](#).

## ICAP

This module allows for the offloading of certain processes to a separate server so that your FortiGate firewall can optimize its resources and maintain the best level of performance possible.

## FortiClient Profiles

FortiClient is an all-in-one comprehensive endpoint security solution that extends the power of Fortinet's Advanced Threat Protection (ATP) to end user devices. As the endpoint is the ultimate destination for malware that is seeking credentials, network access, and sensitive information, ensuring that your endpoint security combines strong prevention with detection and mitigation is critical.

The FortiGate provides network security by defining compliance rules for FortiClient endpoints.

## Proxy Options

Proxy Options includes features you can configure for when your FortiGate is operating in proxy mode, including protocol port mapping, block oversized files/emails, and other web and email options.

## SSL/SSH Inspection

SSL/SSH Inspection (otherwise known as Deep Inspection) is used to scan HTTPS traffic in the same way that HTTP traffic can be scanned. This allows the FortiGate to receive and open up the encrypted traffic on behalf of the client, then the traffic is re-encrypted and sent on to its intended destination.

Individual Deep Inspection profiles can be created, depending on the requirements of the policy. Depending on the profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic
- Configure which SSL protocols will be inspected
- Configure which ports will be associated with which SSL protocols for inspection
- Configure whether or not to allow invalid SSL certificates
- Configure whether or not SSH traffic will be inspected

## Security Profiles/lists/sensors

A profile is a group of settings that you can apply to one or more firewall policies. Each Security Profile feature is enabled and configured in a profile, list, or sensor. These are then selected in a security policy and the settings apply to all traffic matching the policy. For example, if you create an antivirus profile that enables antivirus scanning of HTTP traffic, and select the antivirus profile in the security policy that allows your users to access the World Wide Web, all of their web browsing traffic will be scanned for viruses.

While you can apply more than one security profile to a firewall policy, it is not recommended that you use flow-based profiles and proxy-based profiles in the same firewall policy.

---

Because you can use profiles in more than one security policy, you can configure one profile for the traffic types handled by a set of firewall policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate sets of profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

## Inspection Modes

You can select one of two inspection modes from the **System > Settings** page to control the security profile inspection mode for your FortiGate or VDOM.

- [Proxy-based inspection](#), that reconstructs content passing through the FortiGate unit and inspects the content for security threats, or
- [Flow-based inspection](#), that takes a snapshot of content packets and uses pattern matching to identify security threats in the content.

Each inspection component plays a role in the processing of traffic en route to its destination. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used). In most cases proxy mode is preferred because more security profile features are

available and more configuration options for these individual features are available. Yet, some implementations may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used. While both modes offer significant security, proxy-based provides more features and flow-based is designed to optimize performance.

This section addresses the following topics:

## Proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection, then a mixture of flow-based and proxy-based inspection occurs. Traffic initially encounters the IPS engine, which applies single-pass IPS, Application Control, and CASI, if configured in the firewall policy accepting the traffic.

The traffic is then sent for proxy-based inspection. Proxy-based inspection extracts and caches content, such as files and web pages, from a content session and inspects the cached content for threats. Content inspection takes place in the following order: **VoIP inspection**, **DLP**, **AntiSpam**, **Web Filtering**, **AntiVirus**, and **ICAP**.

If no threat is found, the proxy relays the content to its destination. If a threat is found, the proxy can block the threat and send a replacement message in its stead. The proxy can also block VoIP traffic that contains threats.

## Flow-based inspection

Flow-based inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Web Filtering**, **DLP**, and **AntiVirus**. Flow-based inspection is all done by the IPS engine and, as you would expect, no proxying is involved.

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. **IPS**, **Application Control**, flow-based **Web Filtering**, and flow-based **DLP** filtering happen together. Flow-based **AntiVirus** scanning caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires fewer processing resources than proxy-based inspection and does not change packets, unless a threat is found and packets are blocked. Flow-based inspection cannot apply as many features as proxy inspection. For example, flow-based inspection does not support client comforting and some aspects of replacement messages.

In FortiOS 5.6, flow-based inspection requires the new [NGFW mode](#).

## Changing between proxy and flow mode

You can see which inspection mode your FortiGate is using by looking at the **System Information** widget on your **Dashboard**.

To change inspection modes, go to **System > Settings** and scroll down to **Inspection Mode**. You can select Flow-based to operate in Flow mode or Proxy to operate in Proxy mode.

When you select **Flow-based**, all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

When you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the **System > Settings** page.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left drop-down menu to go to **Global > System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

Switching to flow-based inspection also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

## NGFW profile-based and NGFW policy-based modes

When you select **Flow-based** as the **Inspection Mode**, you have the option in FortiOS 5.6 to select an **NGFW Mode**. **NGFW Profile-based** mode works the same as flow-based mode did in FortiOS 5.4

When selecting NGFW policy-based mode you can also select the SSL/SSH Inspection mode that is applied to all policies.

In the new **NGFW Policy-based** mode, you add applications and web filtering profiles directly to a policy without having to first create and configure Application Control or Web Filtering profiles. See [NGFW Policy Mode \(397035\)](#) on page 96.

The screenshot shows the FortiGate GUI configuration page for inspection modes. It features three rows of settings:

- Inspection Mode:** A toggle switch with 'Flow-based' selected (highlighted in green) and 'Proxy' unselected.
- NGFW Mode:** A toggle switch with 'Profile-based' unselected and 'Policy-based' selected (highlighted in green).
- SSL/SSH Inspection:** A dropdown menu with 'SSL' selected (highlighted in orange) and 'deep-inspection' as the other visible option.

When you change to flow-based inspection, all proxy mode profiles are converted to flow mode, removing any proxy settings. And proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Go to **System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

## CLI syntax

The following CLI commands can be used to configure inspection and NGFW (called "policy" in the CLI) modes:

```
config system settings
```

```

set inspection-mode {proxy | flow}
set policy-mode {standard | ngfw}
end

```

## Comparison of inspection types

The tables in this section show how different security features map to different inspection types and present the strengths and weaknesses of proxy- vs. flow-based inspection.

### Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

| Security Profile Feature | Flow-based inspection | Proxy-based inspection |
|--------------------------|-----------------------|------------------------|
| AntiVirus                | x                     | x                      |
| Web Filter               | x                     | x                      |
| DNS Filter               | x                     | x                      |
| Application Control      | x                     | x                      |
| Intrusion Protection     | x                     | x                      |
| Anti-Spam                |                       | x                      |
| Data Leak Protection     |                       | x                      |
| VoIP                     |                       | x                      |
| ICAP                     |                       | x                      |
| Web Application Firewall |                       | x                      |
| FortiClient Profiles     | x                     | x                      |
| Proxy Options            | x                     | x                      |
| SSL Inspection           | x                     | x                      |
| SSH Inspection           |                       | x                      |
| Web Rating Overrides     | x                     | x                      |
| Web Profile Overrides    |                       | x                      |

## Individual Security Profile considerations

In flow mode, AntiVirus and Web Filter profiles only include flow-mode features. Web filtering and virus scanning are still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

Application control uses flow-based inspection; if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the warning, or replacement, message. However, Application Control will still function.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

If you set flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or AntiSpam profile to a firewall policy.

## Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

### Antivirus features in proxy and flow mode

| Feature                                                   | Proxy | Flow                                      |
|-----------------------------------------------------------|-------|-------------------------------------------|
| Scan Mode (Quick or Full)                                 | no    | yes                                       |
| Detect viruses (Block or Monitor)                         | yes   | yes                                       |
| Inspected protocols                                       | yes   | no (all relevant protocols are inspected) |
| Inspection Options                                        | yes   | yes (not available for quick scan mode)   |
| Treat Windows Executables in Email Attachments as Viruses | yes   | yes                                       |
| Send Files to FortiSandbox Appliance for Inspection       | yes   | yes                                       |
| Use FortiSandbox Database                                 | yes   | yes                                       |
| Include Mobile Malware Protection                         | yes   | yes                                       |

## Web Filter features in proxy and flow mode

| Feature                                                     |                                                       | Proxy | Flow                              |
|-------------------------------------------------------------|-------------------------------------------------------|-------|-----------------------------------|
| FortiGuard category based filter                            |                                                       | yes   | yes (show, allow, monitor, block) |
| Category Usage Quota                                        |                                                       | yes   | no                                |
| Allow users to override blocked categories (on some models) |                                                       | yes   | no                                |
| Search Engines                                              |                                                       | yes   | no                                |
|                                                             | Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex | yes   | no                                |
|                                                             | Restrict YouTube Access                               | yes   | no                                |
|                                                             | Log all search keywords                               | yes   | no                                |
| Static URL Filter                                           |                                                       | yes   | yes                               |
|                                                             | Block invalid URLs                                    | yes   | no                                |
|                                                             | URL Filter                                            | yes   | yes                               |
|                                                             | Block malicious URLs discovered by FortiSandbox       | yes   | yes                               |
|                                                             | Web Content Filter                                    | yes   | yes                               |
| Rating Options                                              |                                                       | yes   | yes                               |
|                                                             | Allow websites when a rating error occurs             | yes   | yes                               |
|                                                             | Rate URLs by domain and IP Address                    | yes   | yes                               |
|                                                             | Block HTTP redirects by rating                        | yes   | no                                |
|                                                             | Rate images by URL                                    | yes   | no                                |
| Proxy Options                                               |                                                       | yes   | no                                |

| Feature                                             | Proxy | Flow |
|-----------------------------------------------------|-------|------|
| Restrict Google account usage to specific domains   | yes   | no   |
| Provide details for blocked HTTP 4xx and 5xx errors | yes   | no   |
| HTTP POST Action                                    | yes   | no   |
| Remove Java Applets                                 | yes   | no   |
| Remove ActiveX                                      | yes   | no   |
| Remove Cookies                                      | yes   | no   |
| Filter Per-User Black/White List                    | yes   | no   |

### AntiVirus Scanning differences between versions of FortiOS 5.x

In FortiOS 5.0, 5.2, 5.4, and 5.6, there are several AntiVirus (AV) scanning inspection modes available. FortiOS 5.0 includes proxy and flow-based virus scanning. FortiOS 5.2 also uses proxy-based and flow-based scanning, but the flow-based mode in FortiOS 5.2 uses a new approach to flow-based scanning (that is sometimes called deepflow or deep flow scanning). FortiOS 5.4 and 5.6 offer another flow-based mode, quick mode, to inspect traffic efficiently.

The databases used for AV scanning does not change from proxy to flow mode unless quick mode is enabled. In flow-based quick mode, a compact antivirus database is used.

AntiVirus scanning examines files in HTTP, HTTPS, email, and FTP traffic for threats as they pass through your FortiGate. If the traffic contains compressed files, they are also examined. Go to the SysAdmin Note on the Fortinet Cookbook site for detailed information on [supported compression formats](#) in antivirus scanning.

If the AV scanner finds a threat such as a virus or some other malware, FortiOS protects your network by blocking the file.

FortiOS includes a number of AntiVirus features that make virus scanning more user-friendly. One of these features, called replacement messages, sends a customizable message to anyone whose file is blocked by AV scanning, to explain what happened and why. Other features make communication between the client and the server more seamless. The availability of these changes depending on the inspection mode.

### Proxy-based AV scanning

Proxy-based AV scanning is the most feature-rich AV scanning mode. This mode uses a proxy to manage the communication between client and server. The proxy extracts content packets from the data stream as they arrive and buffers the content until the complete file is assembled. Once the file is whole, the AV scanner examines the file for threats. If no threats are found, the file is sent to its destination. If a threat is found, the file is blocked.

Because proxy-based scanning is applied to complete files, including compressed files, it provides very effective threat detection. Proxy-based scanning also supports a full range of features, including replacement messages and client comforting, making proxy-based scanning the most user friendly inspection mode. In addition the proxy

manages the communication between the client and the server, improving the user experience. For example, in flow mode if a virus is found, the last part of the file is not downloaded and the connection just times out and the user cannot tell what is going on. In proxy mode, the users gets a message about the file being blocked.

Proxy-based scanning inspects all files under the oversized threshold. Since the FortiGate unit has a limited amount of memory, files larger than a certain size do not fit within the memory buffer. The default buffer size is 10 MB. You can use the `uncompssize limit CLI` command to adjust the size of this memory buffer. Files larger than the threshold are passed to the destination without scanning. You can use the **Oversized File/Email** setting in **Security Profiles > Proxy Options** to block files larger than the antivirus buffer if allowing files that are too large to be scanned is an unacceptable security risk.

During the buffering and scanning procedure, the client must wait. With a default configuration, the file is released to the client only after it is scanned. You can enable client comforting in the **Proxy Options** security profile to feed the client a trickle of data to prevent them from possibly thinking the transfer is stalled and consequently canceling the download.

### Flow-based AV scanning

Although the name "flow-based scanning" is used in FortiOS 5.0, 5.2, 5.4, and 5.6, the different versions handle this mode in very different ways.

#### Flow AV in FortiOS 5.4 and 5.6

In FortiOS 5.4 and 5.6, there are two modes available for flow-based virus scanning: **Quick** and **Full** scan mode. Full mode is the same as flow-based scanning in FortiOS 5.2 (see below). Quick mode uses a compact antivirus database and advanced techniques to improve performance. You can designate quick or full scan mode when configuring the antivirus profile in the GUI. Alternatively, use the following CLI command to enable quick or full mode:

```
config antivirus profile
 edit <profile>
 set scan-mode {quick | full}
 end
```

#### Flow AV in FortiOS 5.2 (deepflow or deep flow)

FortiOS 5.2 introduced a new type of flow-based AV scanning, that is sometimes called deepflow or deep flow, and that takes a hybrid approach where content packets are buffered while simultaneously being sent to their destination. When all of the files packets have been collected and buffered, but before the final packet is delivered, the buffered file is scanned. If a threat is found, the last packet is blocked and the client application has to deal with not getting the completed file. If no threat is found the final packet is sent and the user gets their file.

Deepflow AV scanning is as good as proxy-based AV scanning at detecting threats. There may be a small performance advantage over proxy-based AV as files get larger based on the difference between sending the whole file after analysis and just sending the last packet. Deepflow's most notable limitation is that, just like the flow-based AV in 5.0, it does not support many of the user-friendly features provided by proxy-based AV.

#### Flow AV in FortiOS 5.0

In FortiOS 5.0, flow-based AV scanning examines the content of individual data packets as they pass through the FortiGate. There is no proxy involved so packets are not changed by the proxy and files are not buffered for analysis. Potentially less memory and CPU resources are used, resulting in a potential performance increase compared to using proxy-based mode. FortiOS 5.0 flow-based AV scanning is also not limited by file size.

Flow AV uses the IPS engine and the AV database and is effective at many kinds of threat detection; however, because it can only analyze what is in an individual packet rather than a complete file, flow-based scanning cannot detect some types of malware, including polymorphic code. Malware in documents, compressed files, and some archives are also less likely to be detected.

Flow AV does not actually block files, it stops delivering a file's packets once a threat has been detected. This means that parts of the file may already have been delivered when the threat has been detected and the recipient application is responsible for dealing with the partially complete content.

In addition flow AV can be less user friendly. Replacement messages are not supported and clients may have to wait for sessions to time out without knowing why content has been blocked.

## AntiVirus

This section describes how to configure the antivirus options. From an antivirus profile you can configure the FortiGate unit to apply antivirus protection to HTTP, FTP, IMAP, POP3, SMTP, and NNTP sessions. If your FortiGate unit supports SSL/SSH content scanning and inspection, you can also configure antivirus protection for HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.

In many cases you can just customize the default antivirus profile and apply it to the security policy that accepts the traffic to be virus scanned. You can also create custom antivirus profiles if want to apply different types of virus protection to different traffic.

This Handbook chapter includes [Inside FortiOS: AntiVirus](#) providing readers an overview of the features and benefits of key FortiOS 5.6 components.

For readers needing to delve into greater detail, we provide the following topics:

- [Antivirus concepts](#)
- [Enabling AntiVirus scanning](#)
- [Testing your antivirus configuration](#)
- [Example Scenarios](#)

### Antivirus concepts

The word “antivirus” refers to a group of features that are designed to prevent unwanted and potentially malicious files from entering your network. These features all work in different ways, which include checking for a file size, name, or type, or for the presence of a virus or grayware signature.

The antivirus scanning routines your FortiGate unit uses are designed to share access to the network traffic. This way, each individual feature does not have to examine the network traffic as a separate operation, and the overhead is reduced significantly. For example, if you enable file filtering and virus scanning, the resources used to complete these tasks are only slightly greater than enabling virus scanning alone. Two features do not require twice the resources.

Antivirus scanning examines files for viruses, worms, trojans, and other malware. The antivirus scan engine has a database of virus signatures it uses to identify infections. If the scanner finds a signature in a file, it determines that the file is infected and takes the appropriate action.

### Malware threats

Malware is the general term covering all the different types of threats to your computer safety such as:

- [Viruses](#)
- [Worms](#)
- [Trojan horses](#)
- [Ransomware](#)
- [Scareware](#)
- [Spyware](#)
- [Adware](#)
- [Botnets](#)

- [Phishing](#)
- [Grayware](#)

## Viruses

Viruses are self-replicating code that install copies of themselves into other programs or data files for boot sectors of storage devices. Viruses can often carry a “payload” which performs some undesirable function. These functions can include but are not limited to:

- Stealing drive space
- Stealing CPU cycles
- Accessing private information
- Corrupting data
- Digital defacement or vandalism
- Spamming contact lists

## Worms

A worm is a piece of standalone computer code that replicates itself in order to spread to other computers. It normally uses a computer network to spread itself, using security vulnerabilities on the target computer or network to propagate. Unlike a virus, it does not attach itself to an existing file. Even if there is no payload, worms consume resources such as bandwidth and storage space just through their act of replication.

## Trojan horses

A Trojan horse, or Trojan is malware that is defined by its delivery method. Through the use of social engineering, or some other method, the code is installed on a system by a valid user of the system and like the original Trojan horse there is something more than advertised within the software. Trojans, unlike worms or viruses are generally non-self-replicating. The most common payload of a Trojan is the setting up of a “backdoor” control mechanism to the system that it is installed on.

## Ransomware

Ransomware is a type of malware that, as the name implies, hold the system ransom until payment of some kind is made. It does this by restricting access to the legitimate owner of the system either by encrypting files or locking the system. Usually, a message of some kind is displayed with the demands. Upon payment a utility or key is sent to the user to unlock the system.

## Scareware

Scareware comes in two main flavours; the first tries to convince the user that his computer is infected with some non-existent malware, scaring the user into purchasing the author’s virus removal utility. The utility is nonfunctional or some additional form of malware.

The second form tries to convince the user that the computer has been or is being used for an illegal act, such as being part of a botnet or storing child pornography. Again, the objective is to scare the user into paying to cure something that is not really there.

## Spyware

Spyware is used by its authors to collect information about the user and its computer without the user's knowledge. The end result can be as benign as being better able to target ads, to as criminal as key loggers designed to record account ids and passwords of bank accounts and forward them off to the authors.

## Adware

Adware is not malware per se. It is merely any software that produces advertisements in order to generate revenue for its author. While a lot of people find this inconvenient or irritating, it is not malware. As such, it is not blocked by the antivirus software for being malware.

Software that has adware built into it will be blocked if it has malware in it.

## Botnets

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a "master". These transmissions can be minimally damaging, such as spam, or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer "robot" or "bot" that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

According to a report from Russian-based Kaspersky Labs, botnets -- not spam, viruses, or worms -- currently pose the biggest threat to the Internet. A report from Symantec came to a similar conclusion.

See also: [Botnet protection](#).

## Phishing

Phishing is a social engineering technique that is used to obtain sensitive and confidential information by masquerading as a communication from a trusted entity such as a well-known institution, company, or website. Usually, the malware is not in the communication itself but in the links within the communication.

## Grayware

Grayware programs are unsolicited software programs installed on computers, often without the user's consent or knowledge. Grayware programs are generally considered an annoyance, but they can also cause system performance problems or be used for malicious purposes.

## AntiVirus scanning order

The antivirus scanning function includes various modules and engines that perform separate tasks.

FortiOS has two different modes of antivirus scanning: **proxy-based** and **flow-based**. The reasons for the different modes are performance and granularity. In just about everything relating to security there is a constant balancing act going on. As the level of security and comprehensiveness increases, there is by necessity a decrease in either convenience or performance or both. The increase in processing to scan for more threats requires more resources; resources that are a finite supply on the hardware. Granularity can sometimes be used to mitigate performance impact by scanning for a smaller subset of traffic but this is only recommended when that smaller subset of traffic is the only traffic going through the firewall.

If the traffic on the device is slight, then the impact on the performance will hardly be noticeable. But if the unit is working close to capacity in terms of traffic and there are a lot of files coming through, then there might be a noticeable decline in the performance.

While both modes offer significant security, proxy-based is weighted towards being more thorough and easily configurable, while flow-based is designed to optimize performance.

See [Antivirus scanning differences in FortiOS 5.0, 5.2, 5.4, and 5.6](#) in the [Inspection Modes](#) section for more details on flow vs. proxy inspection modes on your FortiGate.

---

### Proxy-based antivirus scanning order

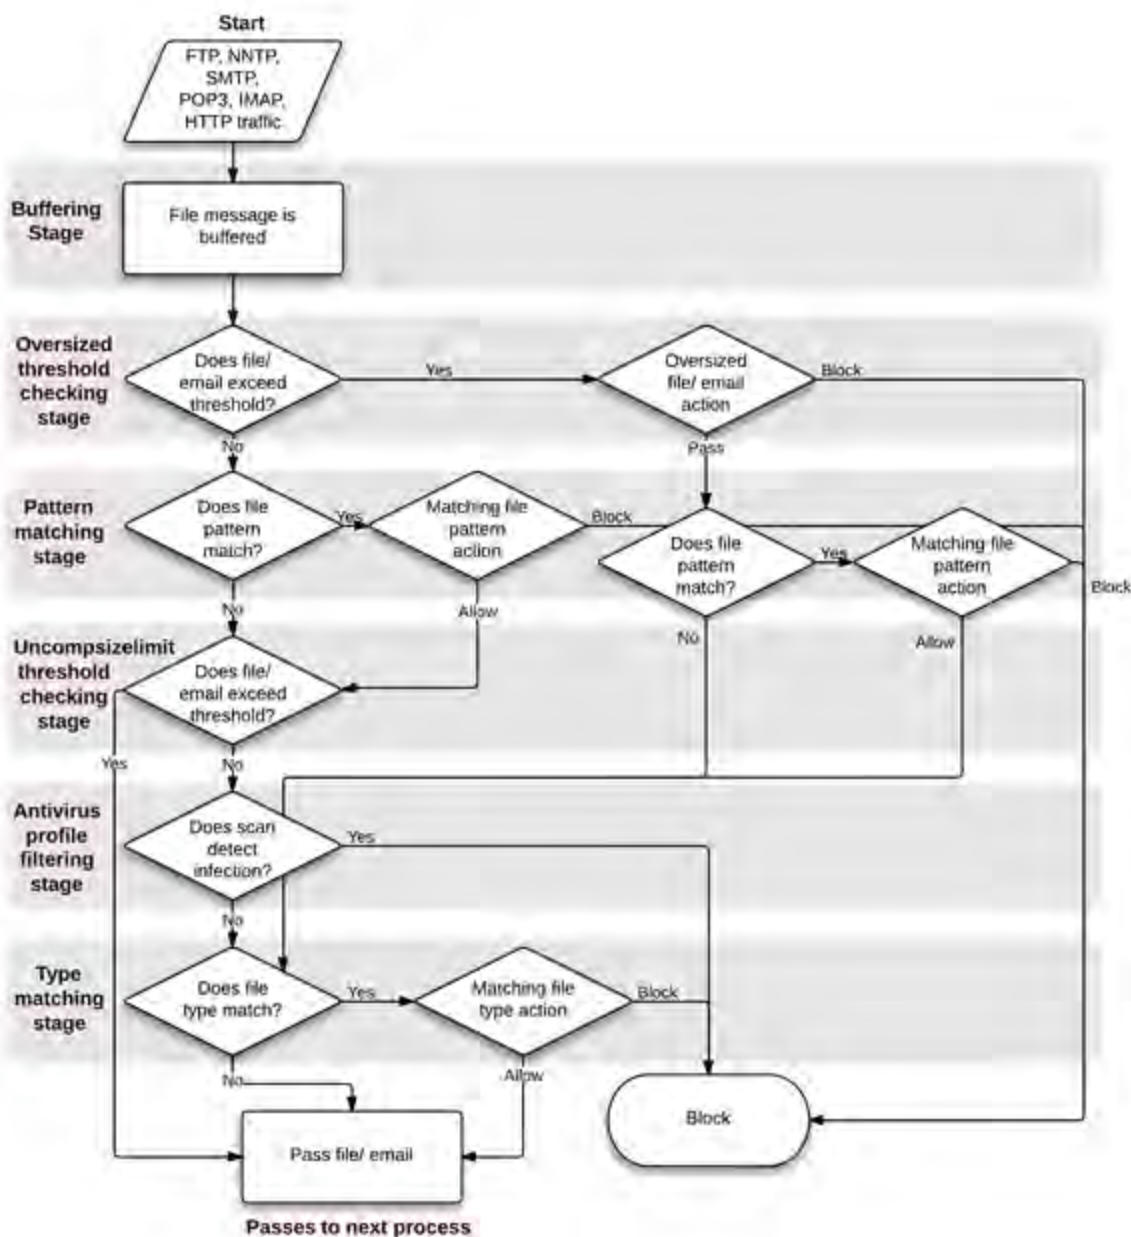

The following figure illustrates the antivirus scanning order when using proxy-based scanning. The first check for oversized files/email is to determine whether the file exceeds the configured size threshold. The `uncompsizelimit` check is to determine if the file can be buffered for file type and antivirus scanning. If the file is too large for the buffer, it is allowed to pass without being scanned. For more information, see the `config antivirus service` command. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics, if enabled.

File filtering includes file pattern and file type scans which are applied at different stages in the antivirus process.

---

## Antivirus scanning order when using the normal, extended, or extreme database

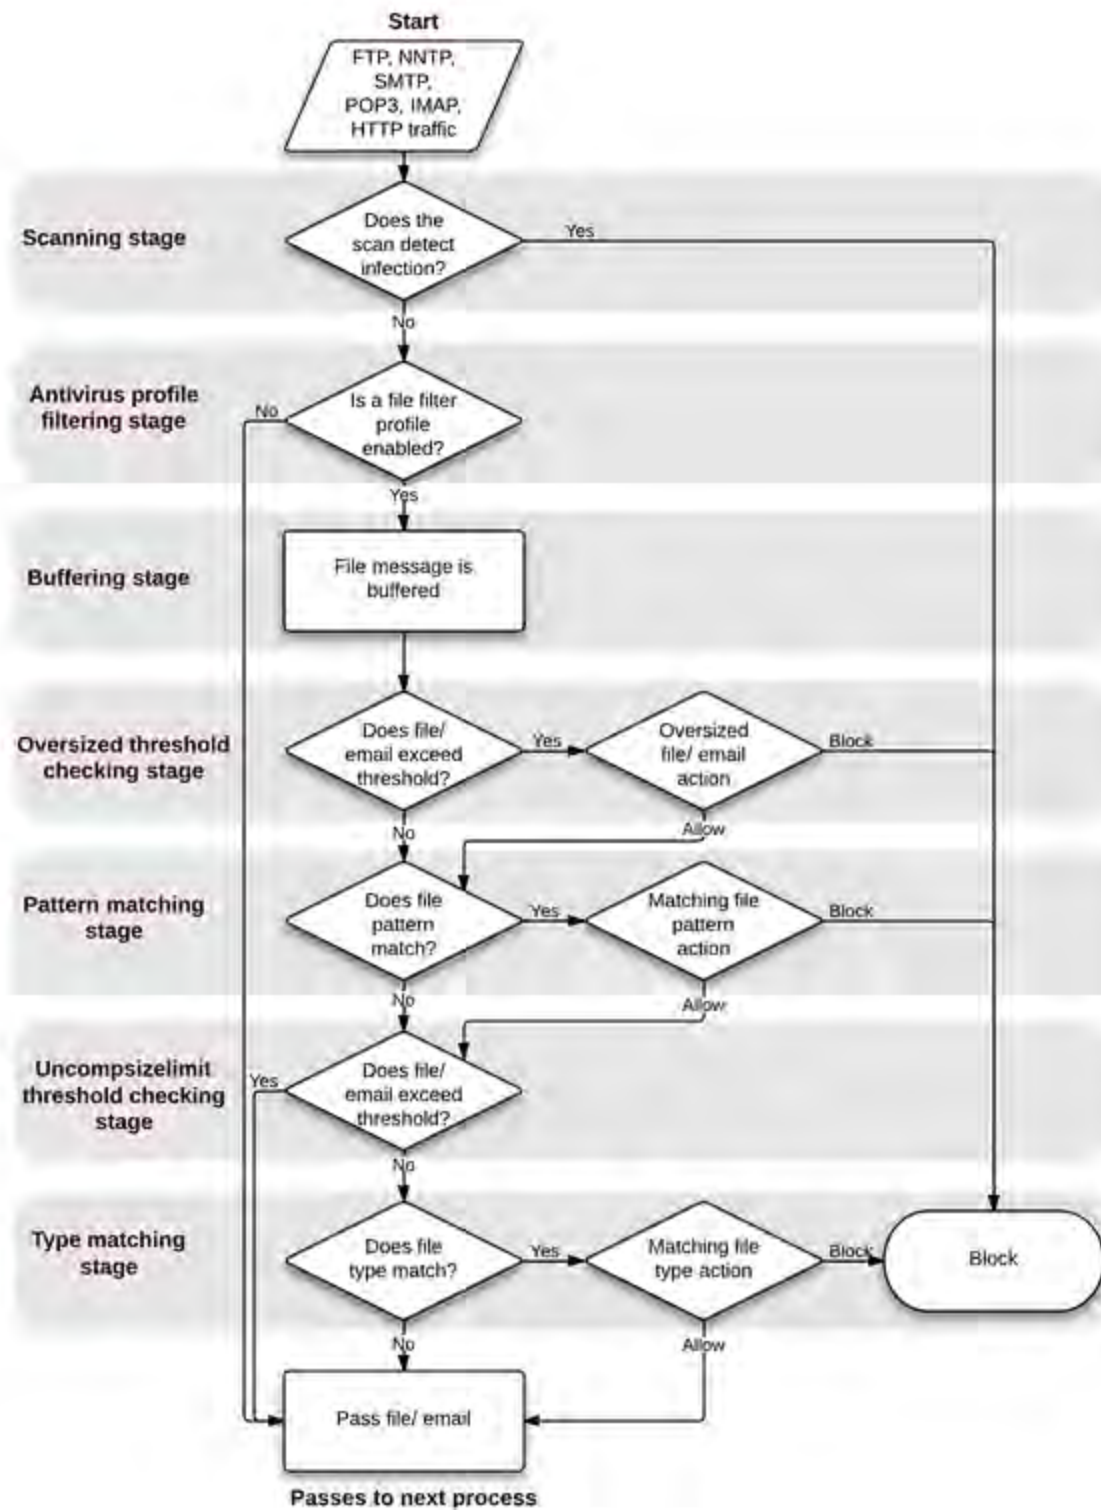

If a file fails any of the tasks of the antivirus scan, no further scans are performed. For example, if the file `fakefile.EXE` is recognized as a blocked file pattern, the FortiGate unit will send the end user a replacement message, and delete or quarantine the file. The unit will not perform virus scan, grayware, heuristics, and file type scans because the previous checks have already determined that the file is a threat and have dealt with it.

### Flow-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using flow-based scanning (i.e. the flow-based database). The antivirus scan takes place before any other antivirus-related scan. If file filter is not enabled, the

file is not buffered. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics if they are enabled.

## AntiVirus databases

The antivirus scanning engine relies on a database of virus signatures to detail the unique attributes of each infection. The antivirus scan searches for these signatures, and when one is discovered, the FortiGate unit determines the file is infected and takes action.

All FortiGate units have the normal antivirus signature database but some models have additional databases you can select for use. Which you choose depends on your network and security needs.

|                 |                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Normal</b>   | Includes viruses currently spreading as determined by the FortiGuard Global Security Research Team. These viruses are the greatest threat. The Normal database is the default selection and it is available on every FortiGate unit.                                |
| <b>Extended</b> | Includes the normal database in addition to recent viruses that are no-longer active. These viruses may have been spreading within the last year but have since nearly or completely disappeared.                                                                   |
| <b>Extreme</b>  | Includes the extended database in addition to a large collection of 'zoo' viruses. These are viruses that have not spread in a long time and are largely dormant today. Some zoo viruses may rely on operating systems and hardware that are no longer widely used. |

If your FortiGate unit supports extended, extreme, or flow-based virus database definitions, you can select the virus database most suited to your needs.

If you require the most comprehensive antivirus protection, enable the extended virus database. The additional coverage comes at a cost, however, because the extra processing requires additional resources.

### To change the antivirus database

Use the CLI to run the following commands:

```
config antivirus settings
 set default-db extended
end
```

## AntiVirus techniques

The first three antivirus features in the list below work in sequence to efficiently scan incoming files and offer your network optimal antivirus protection. The first two features have specific functions, the third, heuristics, protects against new or previously unknown virus threats.

- **Virus scan**

If the file passes the file pattern scan, the FortiGate unit applies a virus scan to it. The virus definitions are kept up-to-date through the FortiGuard Distribution Network (FDN).

- **Grayware protection**

If the file passes the virus scan, it can be checked for grayware. Grayware scanning is an optional function and must be enabled in the CLI if it is to be scanned for along with other malware. Grayware cannot be scanned for on

its own. While done as a separate step, antivirus scanning must be enabled as well.

To enable grayware detection enter the following in the CLI:

```
config antivirus settings
 set grayware enable
end
```

To disable grayware detection enter the following in the CLI:

```
config antivirus settings
 set grayware disable
end
```

Grayware signatures are kept up to date in the same manner as the antivirus definitions.

### • Heuristics

After an incoming file has passed the grayware scan, it is subjected to the heuristics scan. The FortiGate heuristic antivirus engine, if enabled, performs tests on the file to detect virus-like behavior or known virus indicators. In this way, heuristic scanning may detect new viruses, but may also produce some false positive results. You configure heuristics from the CLI.

To set heuristics, enter the following in the CLI:

```
config antivirus heuristic
 set mode {pass | block |disable}
end
```

- “block” enables heuristics and any files determined to be malware are blocked from entering the network.
- “pass” enables heuristics but any files determined to be malware are still allowed to pass through to the recipient.
- “disable” turns off heuristics.

### • FortiGuard AntiVirus

The FortiGuard Antivirus services are included in the regular FortiGuard subscription and include automatic updates of antivirus engines and definitions as well as a DNS black list (DNSBL) through the FortiGuard Distribution Network (FDN).

Current information about your subscription and version numbers can be found at **System > FortiGuard**. This page will also allow the configuration of connections to the FortiGuard Center and how often to check for updates to the antivirus files.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

---

### • Botnet protection

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a “master”. These transmissions can be minimally damaging, such as spam, or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer “robot” or “bot” that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > AntiVirus >** and you will see data for **Botnet IPs** and **Botnet Domains**. You can also block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

### • Quarantine / Source IP ban

As of FortiOS 5.2, quarantine was a place where traffic content was held in storage where it couldn't interact with the network or system. This was removed, but the term quarantine was kept to describe keeping selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

You quarantine a source address through the GUI. Go to **FortiView > Sources**. Right-click on the source address you wish to quarantine and select **Quarantine Source Address**. You can set the duration of the quarantine in days, hours, minutes, or seconds. A User Quarantine ban can be removed in **Monitor > User Quarantine Monitor**.

To configure the AntiVirus security profile to add the source IP address of an infected file to the quarantine or list of banned source IP addresses in the CLI:

```
config antivirus profile
 edit <name of profile>
 config nac-quar
 set infected quar-src-ip
 set expiry 5m
 end
```

If the `quar-src-ip` action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP address will be blocked. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

## FortiGuard AntiVirus updates

To ensure that your system receives the most protection available, all virus definitions and signatures are updated regularly through the FortiGuard AntiVirus services. To configure this feature, go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**. From here you can schedule updates to occur on a consistent weekly, daily, or even hourly basis.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

## FortiSandbox

Not every piece of malware has a signature. This is especially true of new malware and variations on existing malware. FortiOS can upload suspicious files to FortiSandbox for sandbox inspection. When a FortiGate uses sandbox inspection, files are sent to the FortiSandbox. Then the FortiSandbox uses virtual machines (VMs)

running different operating systems to test the file, to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to both the local FortiGate malware database and the FortiGuard AntiVirus signature database.

A file is deemed suspicious when it does not contain a known threat but has characteristics that suggest it may be malware. The characteristics that determine if a file is suspicious are updated by Fortinet to reflect the current threat climate.

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiCloud).

To configure an AntiVirus profile to send files to FortiSandbox, first verify that your FortiSandbox appliance is configured or that your FortiCloud account is active. Then go to **Security Profiles > AntiVirus** and enter the desired **Inspection Options**.

Sending files to the FortiSandbox appliance or to FortiSandbox Cloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is downloaded by the FortiGate every two minutes for live detection.

The **Advanced Threat Protection Statistics** dashboard widget displays the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox. To see FortiSandbox statistics for the last 7 days, go to **Fortinet Security Fabric > Settings**.

## Client Comforting

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit scans it. If no infection is found, the file is sent along to the client. The client initiates the file transfer and nothing happens until the FortiGate finds the file clean, and releases it. Users can be impatient, and if the file is large or the download slow, they may cancel the download, not realizing that the transfer is in progress.

The client comforting feature solves this problem by allowing a trickle of data to flow to the client so they can see the file is being transferred. The default client comforting transfer rate sends one byte of data to the client every ten seconds. This slow transfer continues while the FortiGate unit buffers the file and scans it. If the file is infection-free, it is released and the client will receive the remainder of the transfer at full speed. If the file is infected, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned and potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

---

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

## Enable and configure client comforting

1. Go to **Security Profiles > Proxy Options**.
2. Select a Proxy Options profile and choose **Edit**, or select **Create New** to make a new one.
3. Scroll down to the **Common Options** section and enable the **Comfort Clients** feature. This will set the option on all of the applicable protocols. The ability to set this feature on a protocol by protocol basis exists in the CLI.
4. Select **OK** or **Apply** to save the changes.
5. Apply this Proxy Options profile in any security policy for it to take effect on all traffic handled by the policy.

The default values for Interval and Amount are 10 and 1, respectively. This means that when client comforting takes effect, 1 byte of the file is sent to the client every 10 seconds. You can change these values to vary the amount and frequency of the data transferred by client comforting.

## Oversized files and emails

Downloaded files can range from a few Kilobytes to multiple Gigabytes. A FortiGate doesn't have the memory to allow for a large number of people downloading large files. Imagine the memory required for a team of developers to all download the latest Linux OS distribution at once, in addition to the normal requirements of the firewall. Everything would come to a grinding halt if the FortiGate tried to store each of those Gigabyte+ files in memory. To give you some piece of mind, the chances of malware being in a large file like those is much smaller than in a smaller single Megabyte file, so the threat is somewhat limited, but you will probably want to use your computers antivirus software to scan those large files after they have been downloaded.

A threshold must be set to prevent the resources of the system from becoming overloaded. By default the threshold is 10 MB. Any files larger than the threshold will not be scanned for malware. With a maximum file size threshold in place, it must now be determined what is to be done with the files that are larger than threshold. There are only 2 choices; either the file is passed through without being scanned for malware or the file is blocked. The default action for oversized files is to pass them through.

If you wish to block the downloading of files over the threshold, this can be set within the Proxy Option profile found at **Security Profiles > Proxy Options**, under **Common Options**.

### Enable **Block Oversized File/Email**.

This will reveal an additional option, **Threshold (MB)**. The threshold of the files is set based upon the protocol being used to transfer the file. In the CLI and configuration file, the threshold variable is found in each of the protocol sections within the profile. Changing the value in this field will change the `oversize-limit` value for all of the protocols.

If you wish to change the `oversize-limit` value on the protocols covered in a Proxy Option profile you have two options.

1. You can go into the CLI and change the value manually within each of the protocol sections.
2. You can use the GUI to temporarily block oversized files, and when configuring it change the threshold to the new value that you want. Apply this setting. Then go back to the profile and turn off the block setting. If you now go into the CLI you will find that the configuration file has retained the new `oversize-limit` value.

The settings can be found in the CLI by going to:

```
config firewall profile-protocol-options
 edit <profile_name>
 config <protocol>
 set oversize-limit <size_int>
 end
 end
end
```

## Archive scan depth

The antivirus scanner will open archives and scan the files inside. Archives within other archives, or nested archives, are also scanned to a default depth of twelve nestings. You can adjust the number of nested archives the FortiGate unit will scan with the `uncompressed-nest-limit` CLI command. Further, the limit is configured separately for each traffic type.

### Configuring archive scan depth

For example, this CLI command sets the archive scan depth for SMTP traffic to 5. That is, archives within archives will be scanned five levels deep.

```
config firewall profile-protocol-options
 edit "default"
 config http
 set uncompressed-nest-limit 5
 end
 end
end
```

You can set the nesting limit from 2 to 100.

## Scan buffer size

When checking files for viruses, there is a maximum file size that can be buffered. Files larger than this size are passed without scanning. The default size for all FortiGate models is 10 megabytes.

Archived files are extracted and email attachments are decoded before the FortiGate unit determines if they can fit in the scan buffer. For example, a 7 megabyte ZIP file containing a 12 megabyte EXE file will be passed without scanning with the default buffer size. Although the archive would fit within the buffer, the uncompressed file size will not.

### Configuring the uncompression buffer

In this example, the `uncompressed-oversize-limit` CLI command is used to change the scan buffer size to 20 megabytes for files found in HTTP traffic:

```
config firewall profile-protocol-options
 edit <profile_name>
 config http
 set uncompressed-oversize-limit 20
 end
 end
end
```

The maximum buffer size varies by model. Enter `set uncompressed-oversize-limit ?` to display the buffer size range for your FortiGate unit.

## Windows file sharing (CIFS)

FortiOS supports virus scanning of Windows file sharing traffic. This includes CIFS, SMB, and SAMBA traffic. This feature is applied by enabling SMB scanning in an antivirus profile and then adding this profile to a security policy that accepts CIFS traffic. CIFS virus scanning is available only through flow-based antivirus scanning.

FortiOS flow-based virus scanning can detect the same number of viruses in CIFS/SMB/SAMBA traffic as it can for all supported content protocols.

Note the following about CIFS/SMB/SAMBA virus scanning:

- Some newer version of SAMBA clients and SMB2 can spread one file across multiple sessions, preventing some viruses from being detected if this occurs.
- Enabling CIFS/SMB/SAMBA virus scanning can affect FortiGate performance.
- SMB2 is a new version of SMB that was first partially implemented in Windows Vista.
- Currently SMB2 is supported by Windows Vista or later, and partly supported by Samba 3.5 and fully support by Samba 3.6.
- The latest version of SMB2.2 will be introduced with Windows 8.
- Most clients still use SMB as default setting.

### Configuring CIFS/SMB/SAMBA virus scanning

Use the following command to enable CIFS/SMB/SAMBA virus scanning in an antivirus profile:

```
config antivirus profile
 edit <smb-profile>
 config smb
 set options scan
 end
```

Then add this antivirus profile to a security policy that accepts the traffic to be virus scanned. In the security policy the service can be set to ALL, SAMBA, or SMB.

```
config firewall policy
 edit <policy-id-integer>
 set service ALL
 ...
 set utm-status enable
 set av-profile <smb-profile>
 end
```

## Enabling AntiVirus scanning

Antivirus scanning is configured in an AntiVirus profile, but it is enabled in a firewall policy. Once the use of an AntiVirus profile is enabled and selected in one or more firewall policies, all the traffic controlled by those firewall policies will be scanned according to the settings in that profile.

By going to **System > Feature Visibility**, you can enable or disable two aspects of the AntiVirus Profile.

1. **AntiVirus** will determine if the option to use AntiVirus profiles is available.
2. **Multiple Security Profiles** will determine if you can configure any AntiVirus profiles beyond the default profile.

The enabling or disabling of a feature in **Feature Visibility** refers to its visibility within the GUI, not whether or not the feature's will work. Disabling the AntiVirus Profile feature removes it from the GUI but it can still be accessed and configured in CLI. Since the functionality of the FortiGate unit is based on the contents of the config file any profile referred to by the policy in the configuration will be acted upon. The **Feature Visibility** section is primarily for keeping the GUI clean and uncluttered by features that are not being used by the administrators.

The use of antivirus protection is a minimum standard for security protection. The question left to decide is whether or not you wish to use multiple profiles in your configuration.

## AntiVirus profiles

From **Security Profiles > AntiVirus** you can edit existing profiles or create and configure new antivirus profiles that can then be applied to firewall policies. A profile is specific configuration information that defines how the traffic within a firewall policy is examined and what action may be taken based on the examination.

The configuration of the antivirus profile depends on whether the inspection mode is proxy-based or flow-based. You select the inspection mode by going to the **System > Settings** page. The FortiGate's inspection mode is also displayed on the unit's **Dashboard** in the **System Information** widget.

The discussion of the [differences in antivirus scanning modes](#) helps to understand how this scanning works in proxy- and flow-based inspection, as well as in different versions of FortiOS 5.x.

## Enabling AntiVirus in Proxy-mode - GUI

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an existing profile or create a new one.
  - The default profile will be the one displayed by default.
  - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.
  - If you need to create a new profile you can either select the **Create New** icon (a plus sign within a circle) or select the **List icon** and then select the **Create New** link in the upper left of the window that appears.
3. If you are creating a new profile, write a name for it in the **Name** field.
4. For the **Detect Viruses** field, select either **Block** to prevent infected files from passing throughout the FortiGate or **Monitor** to allow infected files to pass through the FortiGate but to record instances of infection.
5. Under **Inspected Protocols**, enable the protocols you wish to be blocked or monitored.
6. Under **Inspection Options**, you may enable the following: **Treat Windows Executables in Email Attachments as Viruses** and **Include Mobile Malware Protection**.

You may also enable the following options if you have a FortiCloud account active on your FortiGate: **Send Files to FortiSandbox Cloud for Inspection** and **Use FortiSandbox Database**.

---

7. Select **OK** or **Apply**.
8. Add the AntiVirus profile to a firewall security policy.

To view Mobile Malware license and version information, go to **System > FortiGuard** and locate the Mobile Malware section in the **License Information** table.

## Enabling AntiVirus in Flow-mode - GUI

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an existing profile or create a new one.

- The default profile will be the one displayed by default.
  - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.
  - If you need to create a new profile you can either select the **Create New** icon (a plus sign within a circle) or select the **List icon** and then select the **Create New** link in the upper left of the window that appears.
3. If you are creating a new profile, write a name for it in the **Name** field.
  4. Select **Quick** or **Full Scan Mode**(see the discussion of the [differences in antivirus scanning modes](#) for more information).
  5. For the **Detect Viruses** field, select either **Block** to prevent infected files from passing throughout the FortiGate or **Monitor** to allow infected files to pass through the FortiGate but to record instances of infection.
  6. Under **Inspected Protocols**, enable the protocols you wish to be blocked or monitored.
  7. Under **Inspection Options**, you may enable the following: **Treat Windows Executables in Email Attachments as Viruses** and **Include Mobile Malware Protection**.

You may also enable the following options if you have a FortiCloud account active on your FortiGate: **Send Files to FortiSandbox Cloud for Inspection** and **Use FortiSandbox Database**.

8. Select **OK** or **Apply**.
9. Add the AntiVirus profile to a firewall security policy.

## Enabling AntiVirus - CLI

Configure the scan option for each type of traffic you want scanned.

### 1. Configure the AntiVirus profile

```
config antivirus profile
 edit <profile_name>
 set comment "scan and delete virus"
 set replacemsg-group ''
 set scan-botnet-connections block
 set ftgd-analytics suspicious
 config http
 set options scan
 end
 config ftp
 set options scan
 end
 config imap
 set options scan
 end
 config pop3
 set options scan
 end
 config smtp
 set options scan
 end
 config nntp
 set options scan
```

```
end
config smb
 set options scan
end
end
```

2. Add the AntiVirus profile to the Fortigate firewall security policy. When using the CLI, you will need to know the policy ID number.

```
config firewall policy
 edit <policy ID number>
 set av-profile <profile_name>
 set profile-protocol-options default
 end
end
```

## Testing your antivirus configuration

You have configured your FortiGate unit to stop viruses, but you'd like to confirm your settings are correct. Even if you have a real virus, it would be dangerous to use for this purpose. An incorrect configuration will allow the virus to infect your network.

To solve this problem, the European Institute of Computer Anti-virus Research has developed a test file that allows you to test your antivirus configuration. The EICAR test file is not a virus. It cannot infect computers, nor can it spread or cause any damage. It's a very small file that contains a sequence of characters. Your FortiGate unit recognizes the EICAR test file as a virus so you can safely test your FortiGate unit antivirus configuration.

Go to <http://www.fortiguard.com/antivirus/eicartest.html> to download the test file (eicar.com) or the test file in a ZIP archive (eicar.zip).

If the antivirus profile applied to the security policy that allows you access to the Web is configured to scan HTTP traffic for viruses, any attempt to download the test file will be blocked. This indicates that you are protected.

## Example scenarios

The following examples provide sample antivirus configuration scenarios.

### Configuring simple default AntiVirus profile

If performance is not a real concern and the FortiGate's resources are not being stretched, it is perfectly reasonable to create one AntiVirus profile that covers the range of uses found in your environment. This example is one possible default configuration.

Context:

- This is an edited default profile and will be used on all security policies
- It will need to scan for malware on all available protocols.
- Malware, botnets, and grayware should be blocked
- The inspection method should be flow-based
- A current FortiCloud account is available

## Creating the profile - GUI

1. In the following fields, enter the settings shown in the screenshot.
2. Select **Apply**.
3. Enable grayware scanning through the CLI.

```
config antivirus settings
 set grayware enable
end
```

## Creating the profile - CLI

1. Enter the CLI by one of the following methods:
  - SSH through a terminal emulator
  - CLI Console access
  - FortiExplorer's CLI mode
2. Enter the following commands:

```
config antivirus profile
 edit default
 set comment "scan and delete virus"
 set inspection-mode flow-based
 set scan-botnet-connections block
 set ftgd-analytics suspicious
 config http
 set options scan
 end
 config ftp
 set options scan
end
```

```
end
config imap
 set options scan
end
config pop3
 set options scan
end
config smtp
 set options scan
end
config nntp
 set options scan
end
config smb
 set options scan
end
end
```

### 3. Enable grayware scanning

```
config antivirus settings
 set grayware enable
end
```

## Setting up a basic proxy-based AntiVirus profile for email traffic

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable antivirus protection on a FortiGate unit located in a satellite office.

Context:

- The satellite office does not have an internal email server. To send and retrieve email, the employees connect to an external mail server.
- There is a specific firewall security profile that handles the email traffic from the Internet to the mail server. The only traffic on this policy will be POP3 and IMAP and SMTP
- The company policy is to block viruses and connections to botnets.
- The FortiGate unit is a small model and the Internet bandwidth is limited so the policy is to not submit files to the FortiSandbox.

### Creating the profile - GUI

1. In the following fields, enter the indicated values or selections:

|                                                  |                                               |
|--------------------------------------------------|-----------------------------------------------|
| <b>Name</b>                                      | email-av                                      |
| <b>Comments</b>                                  | Scans email traffic from Internet for malware |
| <b>Inspection Mode</b>                           | Proxy                                         |
| <b>Detect Virus</b>                              | Block                                         |
| <b>Send Files to FortiSandbox for Inspection</b> | checked                                       |

|                                                     |         |
|-----------------------------------------------------|---------|
| • <b>Suspicious Files Only</b>                      | checked |
| <b>Detect Connections to Botnet C&amp;C Servers</b> | checked |
| • <b>Block</b>                                      | checked |

2. Check the appropriate protocols:

| Inspected Protocols | Virus Scan and Block |
|---------------------|----------------------|
| <b>HTTP</b>         | checked              |
| <b>SMTP</b>         | checked              |
| <b>POP3</b>         | checked              |
| <b>IMAP</b>         | checked              |
| <b>MAPI</b>         | checked              |
| <b>FTP</b>          | checked              |
| <b>NNTP</b>         | checked              |

3. Select **Apply**.

### Creating the profile - CLI

1. Enter the CLI by one of the following methods:

- SSH through a terminal emulator
- CLI Console widget
- FortiExplorer's CLI mode

2. Enter the following commands:

```
Config antivirus profile
edit "email-av"
set comment "Scans email traffic from Internet for malware"
set inspection-mode proxy
config imap
set options scan
end
config pop3
set options scan
end
config smtp
set options scan
end
end
```

### Adding the profile to a policy

In this scenario the following assumptions will be made:

- The policy that the profile is going to be added to is an IPv4 policy.
- The ID number of the policy is 11.
- The AntiVirus profile being added will be the "default" profile
- The SSL/SSH Inspection profile used will be the "default" profile

FortiClient enforcement has been moved from the Policy page to **Network > Interfaces** to enforce FortiClient registration on a desired LAN interface rather than a policy.

---

### Adding the profile - GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Use your preferred method of finding a policy.
  - If the ID column is available you can use that.
  - You can also choose based on your knowledge of the parameters of the policy
  - Select the policy with ID value of 11
3. In the Edit Policy window, go to the Security Profiles section
4. Turn ON AntiVirus, and in the drop down menu for the field, select default
5. If the AntiVirus profile is proxy-based the Proxy Options field and drop down menu will be revealed.
6. The SSL/SSH Inspection field will automatically be set to ON and one of the profiles will need to be selected from the drop down menu. In this case default is selected.
7. The log options will depend on your requirements and resources but to verify that everything is working properly, it is a good idea to turn ON logging of All Sessions after setting up a new profile and after giving some time for logs to accumulate
8. Turn on Antivirus.
9. Select an antivirus profile.
10. Select **OK** to save the security policy.

### Adding the profile - CLI

To select the antivirus profile in a security policy — CLI

```
config firewall policy
 edit 11
 set utm-status enable
 set profile-protocol-options default
 set av-profile basic_antivirus
 end
```

### Block files larger than 8 MB

#### Set proxy options profile to block files larger than 8 MB

1. Go to **Security Profiles > Proxy Options**.
2. Edit the default or select Create New to add a new one.
3. Scroll down to the common Options Section and place a check in the box next to BlockOversized File/Email
4. The sub line Threshold (MB) will appear with a value field. Enter 8.
5. Select **OK** or **Apply**.

The proxy options profile is configured, but to block files, you must select it in the firewall policies handling the traffic that contains the files you want blocked.

#### To select the Proxy Options profile in a security policy

1. Go to **Policy & Objects > IPv4 Policy** (or **IPv6 Policy**, depending).
2. Edit or create a security policy.
3. Select a proxy-based security profile. You will know that there is a proxy component to the Security Profile because when a Security Profile is Proxy based the Proxy Options field will be visible (for example, select an Antivirus profile that includes proxy scanning).
4. Beside Proxy Options select the name of the MTU proxy options protocol.
5. Select **OK** to save the security policy.
6. Once you complete these steps, any files in the traffic subject to Security Profile scanning handled by this policy that are larger than 8MB will be blocked. If you have multiple firewall policies, examine each to determine if you want to apply similar file blocking the them as well.

## Web filter

This section describes FortiGate web filtering for HTTP traffic. The three main parts of the web filtering function, the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service interact with each other to provide maximum control over what users on your network can view as well as protection to your network from many Internet content threats. Web Content Filter blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic.

This Handbook chapter includes [Inside FortiOS: Web Filtering](#) and provides readers an overview of the features and benefits of key FortiOS 5.6 components.

For further detail than the Inside FortiOS document, we provide the following topics:

### Web filter concepts

Web filtering is a means of controlling the content that an Internet user is able to view. With the popularity of web applications, the need to monitor and control web access is becoming a key component of secure content management systems that employ antivirus, web filtering, and messaging security. Important reasons for controlling web content include:

- lost productivity because employees are accessing the web for non-business reasons
- network congestion — when valuable bandwidth is used for non-business purposes, legitimate business applications suffer
- loss or exposure of confidential information through chat sites, non-approved email systems, instant messaging, and peer-to-peer file sharing
- increased exposure to web-based threats as employees surf non-business-related web sites
- legal liability when employees access/download inappropriate and offensive material
- copyright infringement caused by employees downloading and/or distributing copyrighted material.

As the number and severity of threats increase on the World Wide Web, the risk potential increases within a company's network as well. Casual non-business related web surfing has caused many businesses countless hours of legal litigation as hostile environments have been created by employees who download and view offensive content. Web-based attacks and threats are also becoming increasingly sophisticated. Threats and web-based applications that cause additional problems for corporations include:

- spyware/grayware
- phishing
- pharming
- instant messaging
- peer-to-peer file sharing
- streaming media
- blended network attacks.

**Spyware**, also known as grayware, is a type of computer program that attaches itself to a user's operating system. It does this without the user's consent or knowledge. It usually ends up on a computer because of

something the user does such as clicking on a button in a pop-up window. Spyware can track the user's Internet usage, cause unwanted pop-up windows, and even direct the user to a host web site. For further information, visit the FortiGuard Center.

Some of the most common types of grayware infection occur when:

- downloading shareware, freeware, or other forms of file-sharing services
- clicking on pop-up advertising
- visiting legitimate web sites infected with grayware.

**Phishing** is the term used to describe attacks that use web technology to trick users into revealing personal or financial information. Phishing attacks use web sites and email that claim to be from legitimate financial institutions to trick the viewer into believing that they are legitimate. Although phishing is initiated by spam email, getting the user to access the attacker's web site is always the next step.

**Pharming** is a next generation threat that is designed to identify and extract financial, and other key pieces of information for identity theft. Pharming is much more dangerous than phishing because it is designed to be completely hidden from the end user. Unlike phishing attacks that send out spam email requiring the user to click to a fraudulent URL, pharming attacks require no action from the user outside of their regular web surfing activities. Pharming attacks succeed by redirecting users from legitimate web sites to similar fraudulent web sites that have been created to look and feel like the authentic web site.

**Instant messaging** presents a number of problems. Instant messaging can be used to infect computers with spyware and viruses. Phishing attacks can be made using instant messaging. There is also a danger that employees may use instant messaging to release sensitive information to an outsider.

**Peer-to-peer (P2P)** networks are used for file sharing. Such files may contain viruses. Peer-to-peer applications take up valuable network resources and may lower employee productivity but also have legal implications with the downloading of copyrighted or sensitive company material.

**Streaming media** is a method of delivering multimedia, usually in the form of audio or video to Internet users. Viewing streaming media impacts legitimate business by using valuable bandwidth.

**Blended network threats** are rising and the sophistication of network threats is increasing with each new attack. Attackers learn from each successful attack and enhance and update their attack code to become more dangerous and to spread faster. Blended attacks use a combination of methods to spread and cause damage. Using virus or network worm techniques combined with known system vulnerabilities, blended threats can quickly spread through email, web sites, and Trojan applications. Examples of blended threats include Nimda, Code Red, Slammer, and Blaster. Blended attacks can be designed to perform different types of attacks, which include disrupting network services, destroying or stealing information, and installing stealthy backdoor applications to grant remote access.

## Different ways of controlling access

The methods available for monitoring and controlling Internet access range from manual and educational methods to fully automated systems designed to scan, inspect, rate and control web activity.

Common web access control mechanisms include:

- establishing and implementing a well-written usage policy in the organization on proper Internet, email, and computer conduct
- installing monitoring tools that record and report on Internet usage
- implementing policy-based tools that capture, rate, and block URLs.

The following information shows how the filters interact and how to use them to your advantage.

## Order of web filtering

The FortiGate unit applies web filters in a specific order:

1. URL filter
2. FortiGuard Web Filter
3. web content filter
4. web script filter
5. antivirus scanning.

If you have blocked a FortiGuard Web Filter category but want certain users to have access to URLs within that pattern, you can use the **Override** within the FortiGuard Web Filter. This will allow you to specify which users have access to which blocked URLs and how long they have that access. For example, if you want a user to be able to access [www.example.com](http://www.example.com) for one hour, you can use the override to set up the exemption. Any user listed in an override must fill out an online authentication form that is presented when they try to access a blocked URL before the FortiGate unit will grant access to it.

If you have blocked a FortiGuard Web Filter category but want users within a specific Web Filter profile to have access to URLs within that pattern, you can use the following CLI command below to override (this will have no timeout affiliated to it):

### CLI Syntax:

```
config webfilter profile
 edit <profile>
 config web
 set whitelist exempt-av exempt-dlp exempt-rangeblock extended-log-others
 end
 end
```

This command will set a Web Filter profile that exempts AV, DLP, RangeBlock, and supports extended log by FortiGuard whitelist.

## Inspection Modes

This topic briefly discusses proxy and flow-based inspection modes. For more information on flow vs. proxy inspection modes on your FortiGate and how they impact web filtering, see [Individual Security Profile considerations](#) in the [Inspection Modes](#) section.

### Proxy

Proxy-based inspection involves buffering traffic and examining it as a whole before determining an action. The process of having the whole of the data to analyze allows for the examination of more points of data than the flow-based or [DNS methods](#).

The advantage of a proxy-based method is that the inspection can be more thorough than the other methods, yielding fewer false positive or negative results in the data analysis.

### Flow-based

The flow-based inspection method examines the file as it passes through the FortiGate unit without any buffering. As each packet of the traffic arrives it is processed and forwarded without waiting for the complete file or web page.

The advantage of the flow-based method is that the user sees a faster response time for HTTP requests and there is less chance of a time-out error due to the server at the other end responding slowly.

The disadvantages of this method are: (1) there is a higher probability of a false positive or negative in the analysis of the data; and, (2) a number of security features that can be used in the proxy-based method are not available in the flow-based inspection method. There are also fewer actions available based on the categorization of the website by FortiGuard services.

In flow mode, Web Filter profiles only include flow-mode features. Web filtering is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode.

Configuring Web Filter profiles in flow-mode is different depending on the [NGFW mode](#) selected.

See ["What's new in FortiOS 5.6"](#) on page 2750 and [Individual Security Profile Considerations](#) in the [Inspection Modes](#) section for more details on flow vs. proxy inspection modes on your FortiGate.

---

## FortiGuard Web Filtering Service

FortiGuard Web Filtering is a managed web filtering solution available by subscription from Fortinet. Before you begin to use the FortiGuard Web Filtering options, verify that you have a valid subscription to the service for your FortiGate firewall.

FortiGuard Web Filtering enhances the web filtering features supplied with your FortiGate unit by sorting billions of web pages into a wide range of categories users can allow or block. The FortiGate unit accesses the nearest FortiGuard Web Filtering Service Point to determine the category of a requested web page, and then applies the security policy configured for that user or interface. FortiGuard Web Filtering supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

FortiGuard Web Filtering includes over 45 million individual ratings of web sites that apply to more than two billion pages. Pages are sorted and rated into several dozen categories administrators can allow or block. Categories may be added or updated as the Internet evolves. To make configuration simpler, you can also choose to allow or block entire groups of categories. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

FortiGuard Web Filtering ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. Users can notify the FortiGuard Web Filtering Service Points if they feel a web page is not categorized correctly, so that the service can update the categories in a timely fashion.

### FortiGuard Web Filtering and your FortiGate unit

When FortiGuard Web Filtering is enabled in a web filter or a DNS filter profile, the setting is applied to all firewall policies that use this profile. When a request for a web page appears in traffic controlled by one of these firewall policies, the URL is sent to the nearest FortiGuard server. The URL category is returned. If the category is blocked, the FortiGate unit provides a replacement message in place of the requested page. If the category is not blocked, the page request is sent to the requested URL as normal.

### FortiGuard Web Filtering Actions

The possible actions are:

- **Allow** permits access to the sites within the category.
- **Block** prevents access to sites within the category. Users attempting to access a blocked site will receive a replacement message explaining that access to the site is blocked.
- **Monitor** permits and logs access to sites in the category. You may also enable user quotas when enabling the monitor action.
- **Warning** presents the user with a message, allowing them to continue if they choose.
- **Authenticate** requires a user to authenticate with the FortiGate unit before being allowed access to the category or category group.

The options of actions available will depend on the mode of inspection.

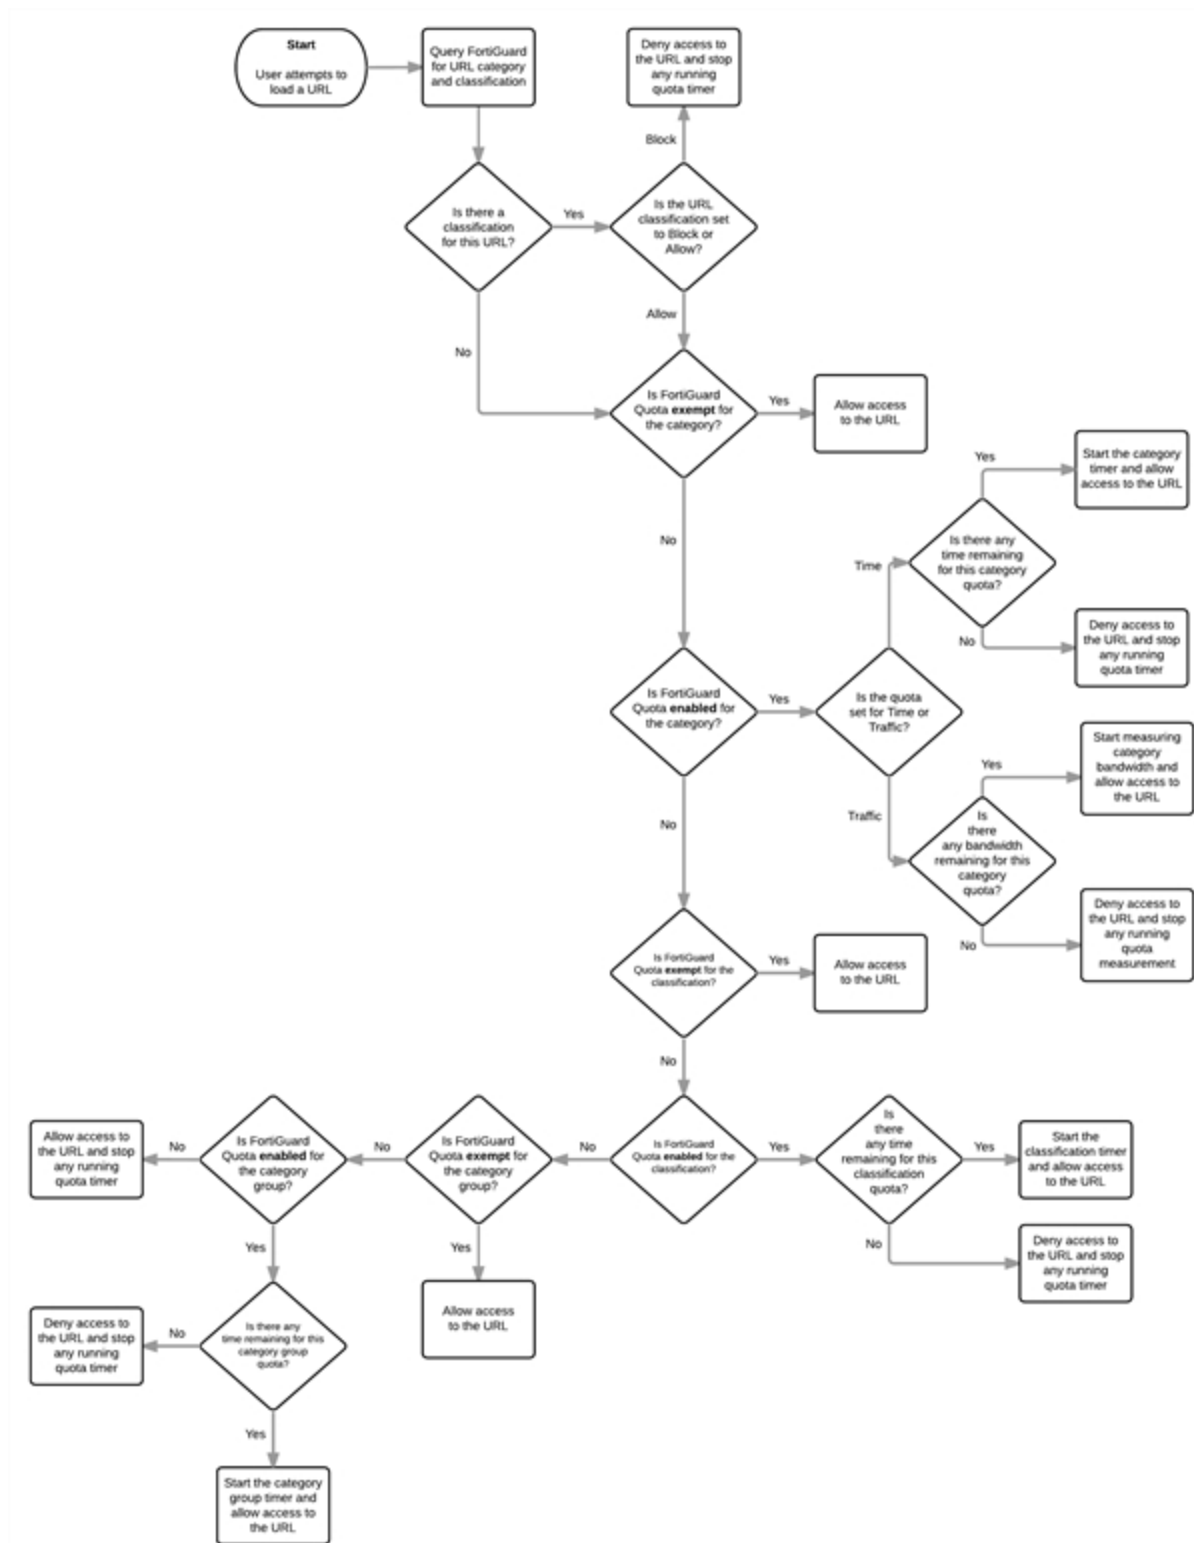

- Proxy - Allow, Block, Monitor, Warning, and Authenticate.
- Flow-based, policy-based - Allow, Deny.
- Flow-based, profile-based - Allow, Block, and Monitor.

Configuring Web Filter profiles in flow-mode is different depending on the [NGFW mode](#) selected.

---

## Web Filtering flowchart

## FortiGuard Web Filtering categories

The following tables identify each FortiGuard web filtering category (organized by group) along with associated category IDs. You can access the current list of category IDs through the CLI.

```
config webfilter profile
edit default
 config ftgd-wf
 config filters
 edit 1
 set category ?
```

For a complete description of each web filtering category, visit <http://www.fortiguard.com/webfilter/categories>.

### Potentially Liable

| ID | Category             |
|----|----------------------|
| 1  | Drug Abuse           |
| 3  | Hacking              |
| 4  | Illegal or Unethical |
| 5  | Discrimination       |
| 6  | Explicit Violence    |

| ID | Category         |
|----|------------------|
| 12 | Extremist Groups |
| 59 | Proxy Avoidance  |
| 62 | Plagiarism       |
| 83 | Child Abuse      |

### Adult/Mature Content

| ID | Category               |
|----|------------------------|
| 2  | Alternative Beliefs    |
| 7  | Abortion               |
| 8  | Other Adult Materials  |
| 9  | Advocacy Organizations |
| 11 | Gambling               |
| 13 | Nudity and Risque      |
| 14 | Pornography            |
| 15 | Dating                 |

| ID | Category                     |
|----|------------------------------|
| 16 | Weapons (Sales)              |
| 57 | Marijuana                    |
| 63 | Sex Education                |
| 64 | Alcohol                      |
| 65 | Tobacco                      |
| 66 | Lingerie and Swimsuit        |
| 67 | Sports Hunting and War Games |

**Bandwidth Consuming**

| ID | Category                        |
|----|---------------------------------|
| 19 | Freeware and Software Downloads |
| 24 | File Sharing and Storage        |
| 25 | Streaming Media and Download    |

| ID | Category                  |
|----|---------------------------|
| 72 | Peer-to-peer File Sharing |
| 75 | Internet Radio and TV     |
| 76 | Internet Telephony        |

**Security Risk**

| ID | Category              |
|----|-----------------------|
| 26 | Malicious Websites    |
| 61 | Phishing              |
|    | Newly Observed Domain |

| ID | Category                |
|----|-------------------------|
| 86 | Spam URLs               |
| 88 | Dynamic DNS             |
|    | Newly Registered Domain |

Newly observed domain (NOD) applies to URLs whose domain name is not rated and were observed for the first time in the past 30 minutes.

Newly registered domain (NRD) applies to URLs whose domain name was registered in the previous 10 days.

**General Interest - Personal**

| ID | Category              |
|----|-----------------------|
| 17 | Advertising           |
| 18 | Brokerage and Trading |
| 20 | Games                 |
| 23 | Web-based Email       |
| 28 | Entertainment         |
| 29 | Arts and Culture      |
| 30 | Education             |
| 33 | Health and Wellness   |
| 34 | Job Search            |
| 35 | Medicine              |

| ID | Category                      |
|----|-------------------------------|
| 47 | Travel                        |
| 48 | Personal Vehicles             |
| 54 | Dynamic Content               |
| 55 | Meaningless Content           |
| 58 | Folklore                      |
| 68 | Web Chat                      |
| 69 | Instant Messaging             |
| 70 | Newsgroups and Message Boards |
| 71 | Digital Postcards             |
| 77 | Child Education               |

| ID | Category                |
|----|-------------------------|
| 36 | News and Media          |
| 37 | Social Networking       |
| 38 | Political Organizations |
| 39 | Reference               |
| 40 | Global Religion         |
| 42 | Shopping                |
| 44 | Society and Lifestyles  |
| 46 | Sports                  |

| ID | Category                    |
|----|-----------------------------|
| 78 | Real Estate                 |
| 79 | Restaurant and Dining       |

### Local categories

Users can define custom or local categories. See [Overriding FortiGuard Website Categorization](#) for details.

### FortiGuard Web Filtering usage quotas

In addition to using category and classification blocks and overrides to limit user access to URLs, you can set a daily quota by category, category group, or classification. Quotas allow access for a specified length of time or a specific bandwidth, calculated separately for each user. Quotas are reset every day at midnight.

Users must authenticate with the FortiGate unit. The quota is applied to each user individually so the FortiGate must be able to identify each user. One way to do this is to configure a security policy using the identity-based policy feature. Apply the web filter profile in which you have configured FortiGuard Web Filter and FortiGuard Web Filter quotas to such a security policy.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

When a user first attempts to access a URL, they're prompted to authenticate with the FortiGate unit. When they provide their user name and password, the FortiGate unit recognizes them, determines their quota allowances, and monitors their web use. The category and classification of each page they visit is checked and FortiGate unit adjusts the user's remaining available quota for the category or classification.

### Quota hierarchy

You can apply quotas to categories and category groups. Only one quota per user can be active at any one time. The one used depends on how you configure the FortiGuard Web Filter.

When a user visits a URL, the FortiGate unit queries the FortiGuard servers for the category of the URL. From highest to lowest, the relative priority of the quotas are:

1. Category
2. Category group

## Configuring Web Filter Profiles

### Web Filter profile page GUI updates (309012)

The GUI for the **Web Filter** security profile and **Web Profile Overrides** pages are changed.

#### Web Filter profile page

- removed multilist for override user group and profile
- replaced FortiGuard categories actions icons with font icons
- added tooltip for **Allow users to override blocked categories** to explain the policy group dependency

#### Web Profile Overrides page

- removed multilist of user, user group, original profile, new profile
- duplicate profile for new profile (for bug #284239)

### Enabling FortiGuard Web Filter

FortiGuard Web Filter is enabled and configured within web filter profiles by enabling FortiGuard Categories. The service is engaged by turning on the Web Filter profile and selecting a profile that has FortiGuard Categories enabled on one or more active policies being run by the firewall.

There is also a system wide setting for the enabling or disabling of FortiGuard Web Filter that is only in the CLI.

```
config system fortiguard
 set webfilter-force-off
```

The two options on this setting are enable or disable. The syntax of the settings name is "force-off" so in order to enable FortiGuard Webfilter you have to choose disable for the setting and enable if you want to turn it off.

## General configuration steps

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and edit an existing one.
3. If you are using FortiGuard Categories, enable the FortiGuard Categories, select the categories and select the action to be performed.
4. Configure any **Category Usage Quotas** needed. (Proxy Mode)
5. Allow blocked override if required. (Proxy Mode)
6. Set up **Safe Search** settings and/or YouTube Education settings. (Proxy & Flow-based)
7. Configure **Static URL Settings**. (All Modes)
8. Configure **Rating Options**. (All Modes)
9. Configure **Proxy Options**.
10. Save the filter and web filter profile.
11. To complete the configuration, you need to select the security policy controlling the network traffic you want to restrict. Then, in the security policy, enable Web Filter and select the appropriate web filter profile from the list.

## Configuring FortiGuard Web Filter settings

FortiGuard Web Filter includes a number of settings that allow you to determine various aspects of the filtering behavior.

### Getting to the Edit Web Filter Profile configuration window

Once you have gotten to the profile configuration window there are a number of settings that can be used, most of which are optional. We will treat each of these options separately, but present the common instructions of how to get to the profile editing page here.

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and then edit an existing one.
  - a. New profile:
    - i. Select the **Create New** icon, in the upper right of the window (looks like a plus sign in a circle) **OR**
    - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Select the **Create New** icon in the upper left.
  - b. Edit existing profile:
    - i. Select the name of the profile that you wish to edit from the drop-down menu **OR**
    - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Highlight the name of the profile from the list and select **Edit** from the options above the list.
  - c. Clone a profile:
    - i. Select **Clone** icon in the upper right corner of the window (looks like one square overlapping another) **OR**
    - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Highlight the name of the profile from the list and select **Clone** from the options above the list.
3. Make sure there is a valid name, and comment if you want.
4. Configure the settings to best achieve your specific requirements
5. Select **Apply** or **OK**, depending on whether you are editing, creating, or cloning a profile.

In older versions of FortiOS there was a character limitation for the URL of 2048 bytes or approximately 321 characters. If the URL you were trying to reach was longer the URL sent to FortiGuard would be truncated and the service would be unable to categorize the site. Starting in version 5 of the firmware, the parsed URL has been increase to 4 Kilobytes, effectively doubling the length of a URL capable of being categorized.

## To configure the FortiGuard Web Filter categories

1. Go to the **Edit Web Filter Profile** window.
2. The category groups are listed in a widget. You can expand each category group to view and configure every sub-category individually within the groups. If you change the setting of a category group, all categories within the group inherit the change.
3. Select the category groups and categories to which you want to apply an action.  
To assign an action to a category left click on the category and select from the pop up menu.
4. Select **Apply** or **OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

If you look at your logs carefully, you may notice that not every URL connection in the log shows a category. They are left blank. If you take one of those URL and enter it in the FortiGuard website designed to show the category for a URL it will successfully categorize it.

The reason for this is that to optimize speed throughput and reduce the load on the FortiGuard servers the FortiGate does not determine a category rating on scripts and css files.

## Configuring FortiGuard Category Quotas

1. Go to the **Edit Web Filter Profile** window
2. Verify that the categories that need to have quotas on them are set to one of these actions:
  - **Monitor**
  - **Warning**
  - **Authenticate**
3. Under **Category Usage Quota**, Select **Create New or Edit**
4. In the **New/Edit Quota** window that pops up, enable or disable the specific categories for that quota.
5. At the bottom of the widget, select a quota type and daily allowance for each user:
  - **Time** -- can be entered in **Hours**, **Minutes**, or **Seconds**.
  - **Traffic** -- can be entered in **Bytes**, **KB**, **MB**, or **GB** The value must be greater than 0.
6. Select **Apply** or **OK**.
7. Continue with any other configuration in the profile
8. Select **Apply** or **OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

---

## Configure Allowed Blocked Overrides

1. Go to the **Edit Web Filter Profile window**.
2. Enable **Allow Blocked Override**
3. In the Apply to Group(s) field select the desired **User Group**
4. In the Assign to Profile field, select the desired profile

## Configure Search Engine Section

There are 2 primary configuration settings in this section.

### Enable Safe Search

#### To enable the Safe Search settings

1. Go to the **Edit Web Filter Profile window**.
2. Enable **Safe Search**
3. Enable Search Engine Safe Search
4. Enable YouTube Filter
  - a. Enter the YouTube User ID in the Text field

Web Filter in flow mode does not support Safe Search

---

## Log All Search Keywords

In the GUI, the configuration setting is limited to a checkbox.

## Configure Static URL Filter

### Web Content Filter

#### To enable the web content filter and set the content block threshold

1. Go to the **Edit Web Filter Profile window**.
2. In the **Static URL Filter section** enable **Web Content Filter**.
3. Select **Create New**.
4. Select the **Pattern Type**.
5. Enter the content **Pattern**.
6. Enter the **Language** from the dropdown menu.
7. Select **Block** or **Exempt**, as required, from the **Action** list.

8. Select **Enable**.
9. Select **OK**.

## Configure Rating Options

### Allow Websites When a Rating error Occurs

In the GUI, the configuration setting is limited to a checkbox.

### Rate URLs by Domain and IP Address

In the GUI, the configuration setting is limited to a checkbox.

### Block HTTP Redirects by Rating

In the GUI, the configuration setting is limited to a checkbox.

### Rate Images by URL (Blocked images will be replaced with blanks)

In the GUI, the configuration setting is limited to a checkbox.

## Configure Proxy Options

### Restrict Google Account Usage to Specific Domains

#### Configuring the feature in the GUI

Go to **Security Profiles > Web Filter**.

In the **Proxy Options** section, check the box next to **Restrict to Corporate Google Accounts Only**.

Use the **Create New** link within the widget to add the appropriate Google domains that will be allowed.

#### Configuring the feature in the CLI

To configure this option in the CLI, the URL filter must refer to a web-proxy profile that is using the Modifying HTTP Request Headers feature. The command is only visible when the action for the entry in the URL filter is set to either allow or monitor.

1. Configure the proxy options:

```
config web-proxy profile
 edit "googleproxy"
 config headers
 edit 1
 set name "X-GoogApps-Allowed-Domains"
 set content "fortinet.com, ladan.ca"
 end
 end
 end
end
```

2. Set a web filter profile to use the proxy options

```
config webfilter urlfilter
 edit 1
 config entries
 edit "*.google.com"
```

```
 set type wildcard
 set action {allow | monitor}
 set web-proxy-profile <profile>
 end
end
end
end
```

In the CLI, you can also add, modify, and remove header fields in HTTP request when scanning web traffic in proxy-mode. If a header field exists when your FortiGate receives the request, its content will be modified based on the configurations in the URL filter.

### Web Resume Download block

In the GUI, the configuration setting is limited to a checkbox.

### Provide Details for Blocked HTTP 4xx and 5xx Errors

In the GUI, the configuration setting is limited to a checkbox.

### HTTP POST Action

### Remove Java Applet Filter

In the GUI, the configuration setting is limited to a checkbox.

### Remove ActiveX Filter

In the GUI, the configuration setting is limited to a checkbox.

### Remove Cookie Filter

In the GUI, the configuration setting is limited to a checkbox.

## Overriding FortiGuard website categorization

In most things there is an exception to the rule. When it comes to the rules about who is allowed to go to which websites in spite of the rules or in this case, policies, it seems that there are more exceptions than to most rules. There are numerous valid reasons and scenarios for exceptions so it follows that there needs to be a way to accommodate this exception.

### The different methods of override

There are two different ways to override web filtering behavior based on FortiGuard categorization of a websites if you are operating in proxy-based inspection.

The second method has two variations in implementation and each of the three has a different level of granularity.

#### 1. Using Alternate Categories

##### ***Web Rating Overrides***

This method manually assigns a specific website to a different Fortinet category or a locally created category.

#### 2. Using Alternate Profiles

### ***Administrative Override or Allow users to override blocked categories***

In this method all of the traffic going through the FortiGate unit, using identity based policies and a Web Filtering profile has the option where configured users or IP addresses can use an alternative Web Filter profile when attempting to access blocked websites.

CLI / flow

## **Using Alternate Categories**

### **Web Rating Overrides**

There are two approaches to overriding the FortiGuard Web Filtering. The first is an identity-based method that can be configured using a combination of identity-based policies and specifically designed webfilter profiles. This is addressed in the Firewall Handbook.

The second method is the system-wide approach that locally (on the FortiGate Firewall) reassigns a URL to a different FortiGuard Category or even subcategory. This is where you can assign a specific URL to the FortiGuard Category that you want to you can also set the URL to one of the Custom Categories that you have created

The Web Rating Overrides option is available because different people will have different criteria for how they categorize websites. Even if the criteria is the same an organization may have reason to block the bulk of a category but need to be able to access specific URLs that are assigned to that category.

A hypothetical example could be that a website, example.com is categorized as being in the Sub-Category Pornography. The law offices of Barrister, Solicitor, and Lawyer do not want their employees looking at pornography at work so they have used the FortiGuard Webfilter to block access to sites that have been assigned to the Category "Pornography". However, the owners of example.com are clients of the law office and they are aware that example.com is for artists that specialize in nudes and erotic images. In this case two approaches can be taken. The first is that the Web Rating Override function can be used to assign example.com to Nudity and Risque instead of Pornography for the purposes of matching the criteria that the law office goes by or the site can be assigned to a Custom Category that is not blocked because the site belongs to one of their clients and they always want to be able to access the site.

Another hypothetical example from the other side of the coin. A private school has decided that a company that specializes in the online selling of books that could be considered inappropriate for children because of their violent subject matter, should not be accessible to anyone in the school. The categorization by Fortinet of the site example2.com is General Interest - Business with the subcategory of Shopping and Auction, which is a category that is allowed at the school. In this case they school could reassign the site to the Category Adult Material which is a blocked category.

### **Local or Custom Categories**

User-defined categories can be created to allow users to block groups of URLs on a per-profile basis. The categories defined here appear in the global URL category list when configuring a web filter profile. Users can rate URLs based on the local categories.

Users can create user-defined categories then specify the URLs that belong to the category. This allows users to block groups of web sites on a per profile basis. The ratings are included in the global URL list with associated categories and compared in the same way the URL block list is processed.

Local categories and local rating features consume a large amount of CPU resources; use these features as little as possible.

The local assignment of a category overrides the FortiGuard server ratings and appear in reports as “Local” Categories or “Custom” Categories depending on the context.

### CLI commands

In the CLI, the term is local category.

To create a local category:

```
config webfilter ftgd-local-cat
 edit local_category_1
 set id 140
 end
```

To set a rating to a Local Category:

```
config webfilter ftgd-local-rating
 edit <url_str>
 set rating {[<category_int>] [group_str] . . .]
 set status {enable | disable}
 end
```

### GUI commands

In the GUI **Local Categories** appears on the **Edit Web Filter** profile page and **Custom Categories** on the **Web Rating Overrides** page, if your FortiGate is in proxy-based or flow-based, profile-based inspection. If your FortiGate is operating with flow-based inspection and the policy-based NGFW mode, then you will not see the **Edit Web Filter** profile page.

Both these features will be used to create local categories and to apply actions to them.

### Creating a Local or Custom Category

1. Go to **Security Profiles > Web Rating Overrides**.
2. Select **Custom Categories** in the top menu bar.
3. In the new window, click on **Create New**.
4. Enter the name of the custom category.
5. Select **OK**.

### Configuring Web Rating Overrides

#### Using the GUI

1. Go to **Security Profiles > Web Rating Overrides**.
2. Select **Create New**
3. Type in the **URL** field the URL of the Website that you wish to recategorize. Do not use wildcard expressions when typing in the URL.
4. Select the **Lookup Rating** button to verify the current categorization assigned to the URL.
5. Change the **Category** field to one of the more applicable options from the drop down menu, for example, one of the custom categories just created.
6. Change the **Sub-Category** field to a more narrowly defined option within the main category.
7. Select **OK**.

It is usually recommended that you choose a category that you know will be addressed in existing Web Filter profiles so that you will not need to engage in further configuration.

## Applying an Action to a Local or Custom Category

1. Go to **Security Profiles > Web Filter**.
2. Expand the **Local Categories** in the list of FortiGuard categories.
3. Right-click on a category from the list and set the action to **Allow**, **Block**, **Monitor**, **Warning**, **Authenticate**, or **Disable**.
4. Select **Apply**.

You cannot apply an action to a local category when operating in flow-based NGFW policy-based mode.

## Local Category scenarios

### Scenario 1: The configuration of the domain name overrides the configuration for the subdirectory.

Depending on the URL specified or other aspects of configuration, the configuration of a local or custom category may not take effect. Consider a scenario where you have defined:

- example.com – local rating as “category 1”, action set to Block
- example.com/subdirectory – local rating as “category 2”, action set to Monitor
- example.com/subdirectory/page.html – local rating as “category 3”, action set to Warning.

If a user browses to “example.com”, access will be blocked. If a user browses to example.com/subdirectory, access will also be blocked, even though that address was configured to be part of category2. The configuration of the domain name overrides the configuration for the subdirectory.

However, if you configure a specific HTML page differently than the domain name, then that configuration will apply. In this scenario, the user will see a Warning message but will be able to pass through to the page.

### Scenario 2: User-defined local ratings and SNI matches

In this scenario, local categories are defined and sites are added to those categories.

- There is no behavioral difference if the hostname is sent from ClientHello SNI or from HTTP request-url.
- The SNI will be used as hostname for https certificate-inspection or ssl-exempt.
- If a valid SNI exist, then SNI will be used as the domain name for url rating instead of CN in the server certificate.
- For the local rating, “example.com” will match “test.example.com”, but will not match “another\_example.com”.

## Using Alternate Profiles

### Allow Blocked Overrides or Web Overrides

The Administrative Override feature for Web Filtering is found by going to **Security Profiles > Web Filter** and then enabling **Allow users to override blocked categories**.

## The Concept

When a Web filter profile is overridden, it does not necessarily remove all control and restrictions that were previously imposed by the Web Filter. The idea is to replace a restrictive filter with a different one. In practice, it makes sense that this will likely be a profile that is less restrictive than the original one but there is nothing that forces this. The degree to which the alternate profile is less restrictive is open. It can be as much as letting the user access everything on the Internet or as little as allowing only one additional website. The usual practice is to have as few alternate profiles as are needed to allow approved people to access what they need during periods when an exception to the normal rules is needed but still having enough control that the organization's web usage policies are not compromised.

You are not restricted to having only one alternative profile as an option to the existing profile. The new profile depends on the credentials or IP address making the connection. For example, John connecting through the "Standard" profile could get the "Allow\_Streaming\_Video" profile while George would get the "Allow\_Social\_Networking\_Sites" profile.

The other thing to take into account is the time factor on these overrides. They are not indefinite. The longest that an override can be enabled is for 1 year less a minute. Often these overrides are set up for short periods of time for specific reasons such as a project. Having the time limitation means that the System Administrator does not have to remember to go back and turn the feature off after the project is finished.

## Identity or Address

In either case, these override features -- for specified users, user groups or IP addresses -- allow sites blocked by Web Filtering profiles to be overridden for a specified length of time. The drawback of this method of override is that it takes more planning and preparation than the rating override method. The advantage is that once this has been set up, this method requires very little in the way of administrative overhead to maintain.

When planning to use the alternative profile approach keep in mind the following: In Boolean terms, one of the following "AND" conditions has to be met before overriding the Web Filter is possible.

### Based on the IP address:

- The Web Filter profile must be specified as allowing overrides
- AND the user's computer is one of the IP addresses specified
- AND the time is within the expiration time frame.

While the conditions are fewer for this situation, there is less control over who has the ability to bypass the filtering configured for the site. All someone has to do is get on a computer that is allowed to override the Web Filter and they have access.

### Based on user group:

- The Web Filter profile must be specified as allowing overrides
- AND the policy the traffic is going through must be identity based
- AND the user's credentials matches the identity credentials specified
- AND the time is within the expiration time frame.

This method is the one most likely to be used as it gives more control in that the user has to have the correct credential and is more versatile because the user can use the feature from any computer that uses the correct policy to get out on the Internet.

## Settings

When using an alternate profile approach to Web Filter overrides, the following settings are used to determine authentication and outcome. Not every setting is used in both methods but enough of them are common to describe them collectively.

### Apply to Group(s)

This is found in the Allow Blocked Overrides configuration. Individual users can not be selected. You can select one or more of the User Groups that are recognized by the FortiGate unit, whether they are local to the system or from a third part authentication device such as a AD server through FSSO.

### Original Profile

This is found in the Administrative Override configuration. In the Allow Blocked Overrides setting the configuration is right inside the profile so there is no need to specify which profile is the original one, but the Administrative Override setup is done separately from the profiles themselves.

### Assign to Profile or New Profile

Despite the difference in the name of the field, this is the same thing in both variations of the feature. You select from the drop down menu the alternate Web Filter Profile that you wish to set up for this override.

### Scope or Scope Range

When setting up the override in the "Allow Blocked Overrides" variation, you are given a drop-down menu next to the field name Scope while in the Administrative Override configuration you are asked to select a radio button next to the same options. In both cases this is just a way of selecting which form of credentials will be required to approve the overriding of the existing Web Filter profile.

When the Web Filter Block Override message page appears it will display a field named "Scope:" and depending on the selection, it will show the type of credentials used to determine whether or not the override is allowed. The available options are:

- **User**  
This means that the authentication for permission to override will be based on whether or not the user is using a specific user account.
- **User Group**  
This means that the authentication for permission to override will be based on whether or not the user account supplied as a credential is a member of the specified User Group.
- **IP**  
This means that the authentication for permission to override will be based on the IP address of the computer that was used to authenticate. This would be used with computers that have multiple users. Example: If Paul logs on to the computer, engages the override using his credentials and then logs off, if the scope was based on the IP address of the computer, anybody logging in with any account on that computer would now be using the alternate override Web Filter profile.

When entering an IP address in the Administrative Override version, only individual IP addresses are allowed.

### Differences between IP and Identity based scope

- Using the IP scope does not require the use of an Identity based policy.
- When using the Administrative Override variation and IP scope, you may not see a warning message when you change from using the original Web Filter profile to using the alternate profile. There is no requirement for credentials from the user so, if allowed, the page will just come up in the browser.

- **Ask**

This option is available only in the "Allowed Blocked Overrides" variation and when used configures the message page to ask which scope the user wished to use. Normally, when the page appears the scope options are greyed out and not editable, but by using the ask option the option is dark and the user can choose from the choice of:

- User
- User Group
- IP Address

- **Switch Duration**

The Administrative Override sets a specified time frame that is always used for that override. The available options are:

- **Predefined**

Using this setting will mean that what ever is set as the duration will be the length of time that the override will be in effect. If the duration variable is set to 15 minutes the length of the override will always be 15 minutes. The option will be visible in the Override message page but the setting will be greyed out.

- **Ask**

Using this setting will give the person the option of setting the duration to the override when it is engaged. The user can set the duration in terms of Day, Hours and or Minutes.

- **Duration**

Duration is one of the areas where the two variations take a different approach, on two aspects of the setting. As already indicated the "Administrative Override" only uses a static time frame there is no option for the user to select on the fly how long it will last. The other way in which the two variation differ is that the "Allow Blocked Overrides" starts the clock when the user logs in with his credentials. For example, if the duration is 1 hour and John initiates an override at 2:00 p.m. on January 1, at the end of that hour he will revert back to using the original profile but he can go back and re-authenticate and start the process over again. The Administrative override variation starts the clock from when the override was configured, which is why it shows an expiration date and time when you are configuring it.

This option, which is available when the Switch Mode is set to Predefined is the time in minutes that the override will last when engaged by the user.

When setting up a constant duration in the Web Based Interface, minutes is the only option for units of time. To set a longer time frame or to use the units of hours or days you can use the CLI.

```
config webfilter profile
 edit <name of webfilter profile>
 config override
 set ovr-dur <###d##h##m>
 end
```

When configuring the duration you don't have to set a value for a unit you are not using. If you are not using days or hours you can use:

```
set ovrd-dur 30m
```

instead of:

```
set ovrd-dur 0d0h30m
```

However, each of the units of time variable has their own maximum level:

```
###d cannot be more than 364
```

```
##h cannot be more than 23
```

```
##m cannot be more than 59
```

So the maximum length that the override duration can be set to is 364 days, 23 hours, and 59 minutes.

## Using cookies to authenticate users in a Web Filter override

Cookies can be used to authenticate users when a web filter override is used. This feature is available in CLI only.

### CLI Syntax:

```
config webfilter cookie-ovrd
 set redir-host <name or IP>
 set redir-port <port>
end

config webfilter profile
 edit <name>
 config override
 set ovrd-cookie [allow | deny]
 set ovrd-scope [user | user-group | ip | ask]
 set profile-type [list | radius]
 set ovrd-dur-mode [constant | ask]
 set ovrd-dur <duration>
 set ovrd-user-group <name>
 set profile <name>
 end
 end
end
```

## Web Profile Overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. The default is 15 minutes.

Temporary access can also be granted to a user, user group, or source IP address by enabling **Allow users to override blocked categories** in a Web Filter security profile and applying that profile to the appropriate policy. In this scenario, the user will have to authenticate to gain access.

When Web Profile Overrides is in effect, a blocked access page or replacement message will not appear and authentication will not be required.

If your FortiGate is operating in flow-based inspection and policy-based NGFW mode, then you cannot create a web profile override.

## Creating a Web Profile Override

Before creating a Web Profile Override, you will have to configure a user or user group if not granting temporary access to a Source IP. You will also have to configure the Web Filter security profile to be applied to the override.

1. Go to **Security Profiles > Web Profile Overrides**.
2. Select **Create New**.

3. Select:
  - The **Scope Range: User** and **User Group** should be previously configured under **User & Device**
  - The **Original Profile** that applied to the scope range.
  - The **New Profile** to apply for the override
  - The time when the override **Expires**; default is 15 minutes

## SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch for the supported search sites enforces its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature. For example, on a Google search it would mean adding the string "&safe=active" to the URL in the search.

The search sites supported are:

- Google
- Yahoo

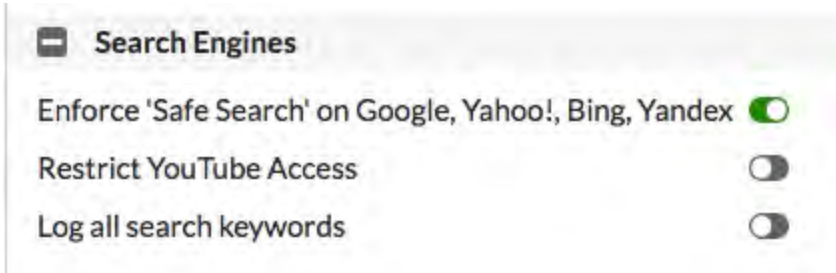

- Bing
- Yandex

You can only enable SafeSearch with proxy-based inspection mode.

### Enabling SafeSearch - GUI

1. Go to **Security Profiles > Web Filter** and edit or create a policy.
2. Expand **Search Engines**

### Enabling SafeSearch - CLI

```
config webfilter profile
 edit default
 config web
 set safe-search <url>
 end
 end
```

This enforces the use of SafeSearch in traffic controlled by the firewall policies using the web filter you configure.

### Search Keywords

There is also the capability to log the search keywords used in the search engines.

## YouTube Education Filter

YouTube for Schools was a way to access educational videos from inside a school network. This YouTube feature gave schools the ability to access a broad set of educational videos on YouTube EDU and to select the specific videos that are accessible from within the school network.

Google decided to stop supporting YouTube for Schools (YTfS) as of July 1, 2016. Consequently, the current YouTube safe search does not work anymore.

Google provides an article entitled "[Restrict YouTube content on your network or managed devices](#)" on its support site. At this time, Google offers two options to restrict inappropriate content: DNS and HTTP header.

In FortiOS 5.6 with inspection mode set to proxy-based, in a Web Filter profile under **Search Engines** you can select **Restrict YouTube Access** and select either **Strict** or **Moderate**.

## Search Engines

Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex ☐

Restrict YouTube Access ☒

**Strict** Moderate

Log all search keywords ☐

## Static URL Filter

You can allow or block access to specific URLs by adding them to the **Static URL Filter** list. The filter allows you to block, allow, or monitor URLs by using patterns containing text, regular expressions, or wildcard characters. The FortiGate unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message instead.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to ftp://ftp.example.com. Instead, use firewall policies to deny ftp connections.

When adding a URL to the URL filter list, follow these rules:

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and file name to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls access to the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.

URLs with an action set to exempt or monitor are not scanned for viruses. If users on the network download files through the FortiGate unit from a trusted web site, add the URL of this web site to the URL filter list with an action to pass it so the FortiGate unit does not virus scan files downloaded from this URL.

## URL formats

### How URL formats are detected when using HTTPS

Filter HTTPS traffic by entering a top level domain name, for example, `www.example.com` if:

- your unit does not support SSL content scanning and inspection
- you have selected the **URL filtering** option in web content profile for **HTTPS content filtering mode** under **Protocol Recognition**.

HTTPS URL filtering of encrypted sessions works by extracting the CN from the server certificate during the SSL negotiation. Since the CN only contains the domain name of the site being accessed, web filtering of encrypted HTTPS sessions can only filter by domain names.

If your unit supports SSL content scanning and inspection and if you have selected Deep Scan, you can filter HTTPS traffic in the same way as HTTP traffic.

### How URL formats are detected when using HTTP

URLs with an action set to Exempt are not scanned for viruses. If users on the network download files through the unit from trusted web site, add the URL of this web site to the URL filter list with an action set to exempt so the unit does not virus scan files downloaded from this URL.

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and filename to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns created using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.
- Fortinet URL filtering supports standard regular expressions.

If virtual domains are enabled on the unit, web filtering features are configured globally. To access these features, select **Global Configuration** on the main menu.

---

### URL Filter actions

You can select one of four actions for how traffic will be treated as it attempts to reach a site in the list.

#### Block

Attempts to access any URLs matching the URL pattern are denied. The user will be presented with a replacement message.

#### Allow

Any attempt to access a URL that matches a URL pattern with an allow action is permitted. The traffic is passed to the remaining antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters, and antivirus scanning.

**Allow** is the default action. If a URL does not appear in the URL list, it is permitted.

## Monitor

Traffic to, and reply traffic from, sites matching a URL pattern with **Monitor** action applied will be allowed through in the same way as the **Allow** action. The difference with the **Monitor** action is that a log message will be generated each time a matching traffic session is established. The requests will also be subject to all other Security Profiles inspections that would normally be applied to the traffic.

## Exempt

**Exempt** allows trusted traffic to bypass the antivirus and DLP proxy operations by default, but it functions slightly differently. In general, if you're not certain that you need to use the **Exempt** action, use **Monitor**.

Using the static URL filter to exempt scanning also prevents SSL inspection.

---

HTTP 1.1 connections are persistent unless declared otherwise. This means the connections will remain in place until closed or the connection times out. When a client loads a web page, the client opens a connection to the web server. If the client follows a link to another page on the same site before the connection times out, the same connection is used to request and receive the page data.

When you add a URL pattern to a URL filter list and apply the **Exempt** action, traffic sent to and replies traffic from sites matching the URL pattern will bypass all antivirus proxy operations. The connection itself inherits the exemption. This means that all subsequent reuse of the existing connection will also bypass all antivirus proxy operations. When the connection times out, the exemption is cancelled.

For example, consider a URL filter list that includes `example.com/files` configured with the **Exempt** action. A user opens a web browser and downloads a file from the URL `example.com/sample.zip`. This URL does not match the URL pattern so it is scanned for viruses. The user then downloads `example.com/files/beautiful.exe` and since this URL does match the pattern, the connection itself inherits the exempt action. The user then downloads `example.com/virus.zip`. Although this URL does not match the exempt URL pattern, a previously visited URL did, and since the connection inherited the exempt action and was re-used to download a file, the file is not scanned.

If the user next goes to an entirely different server, like `example.org/photos`, the connection to the current server cannot be reused. A new connection to `example.org` is established. This connection is not exempt. Unless the user goes back to `example.com` before the connection to that server times out, the server will close the connection. If the user returns after the connection is closed, a new connection to `example.com` is created and it is not exempt until the user visits a URL that matches the URL pattern.

Web servers typically have short time-out periods. A browser will download multiple components of a web page as quickly as possible by opening multiple connections. A web page that includes three photos will load more quickly if the browser opens four connections to the server and downloads the page and the three photos at the same time. A short time-out period on connections will close the connections faster, allowing the server to avoid unnecessarily allocating resources for a long period. The HTTP session time-out is set by the server and will vary with the server software, version, and configuration.

Using the **Exempt** action can have unintended consequences in certain circumstances. You have a web site at `example.com` and since you control the site, you trust the contents and configure `example.com` as exempt. But `example.com` is hosted on a shared server with a dozen other different sites, each with a unique domain name. Because of the shared hosting, they also share the same IP address. If you visit `example.com`, your connection

your site becomes exempt from any antivirus proxy operations. Visits to any of the 12 other sites on the same server will reuse the same connection and the data you receive is exempt from being scanned.

Use of the **Exempt** action is not suitable for configuration in which connections through the FortiGate unit use an external proxy. For example, you use proxy.example.net for all outgoing web access. Also, as in the first example, URL filter list that includes a URL pattern of `example.com/files` configured with the **Exempt** action. Users are protected by the antivirus protection of the FortiGate unit until a user visits a URL that matches the `example.com/files` URL pattern. The pattern is configured with the **Exempt** action so the connection to the server inherits the exemption. With a proxy however, the connection is from the user to the proxy. Therefore, the user is entirely unprotected until the connection times out, no matter what site he visits.

Ensure you are aware of the network topology involving any URLs to which you apply the **Exempt** action.

## Status

The Web Site Filter has the option to either enable or disable individual web sites in the list. This allows for the temporary removal of the actions against a site so that it can be later reengaged without having to rewrite the configuration.

## Configuring a URL filter

You can only set a Static URL Filter with proxy-based inspection mode and flow-based inspection mode in profile-based NGFW mode.

For this example, the URL `www.example*.com` will be used. You configure the list by adding one or more URLs to it.

### To add a URL to a URL filter

1. Go to **Security Profiles > Web Filter**.
2. Create a new web filter or select a one to edit.
3. Expand **Static URL Filter**, enable **URL Filter**, and select **Create**.
4. Enter the URL, without the "http", for example: `www.example*.com`.
5. Select a **Type: Simple**, **Reg. Expression**, or **Wildcard**. In this example, select **Wildcard**.
6. Select the **Action** to take against matching URLs: **Exempt**, **Block**, **Allow**, or **Monitor**.
7. Confirm that **Status** is enabled.
8. Select **OK**.

### 'Simple' Filter type

If you select the **Simple** filter type for a URL filter, the syntax is performing an exact match. Note, however, that the domain and path are separate entities in HTTP despite the fact that a user types them as a single entity and, in the case of 'simple', the rules for each part (domain and path) are different.

### The 'domain' part

For the domain part, the goal of the 'simple' format is to make it easy to block a domain and all its subdomains, such that the admin only has to type "address.xy" to block "address.xy", "www.address.xy", "talk.address.xy", etc. but *not* block "youraddress.xy" or "www.youraddress.xy" which are different domains from "address.xy".

Also, the actual domain does not include `http://` or `https://` so this should *not* be entered or the URL filter will try to match a domain starting with `http`. For this reason, when you enter `http://` in the URL filter via the GUI, it is automatically removed.

A trailing '/' with the domain is not needed. The GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

---

### The 'path' part

For the path part, an exact match takes place. For example:

`www.address.xy/news`

blocks anything that starts with that exact path. So this matches:

`www.address.xy/newsies`  
`www.address.xy/newsforyou`  
`www.address.xy/news/co`  
*etc.*

Also:

`www.address.xy/new`

likewise blocks the same as above but includes:

`/newt`  
`/newp`  
*etc.*

which is a much broader filter, matching:

`www.address.xy/newstand/co`  
`www.address.xy/news/co`  
*etc.*

In other words, the more you specify of the path, the more strictly it will match.

Here as well a trailing '/' with the URL path is not needed, the GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

---

### Referrer URL

A new variable has been added to the Static URL Filter: `referrer-host`. If a referrer is specified, the hostname in the referrer field of the HTTP request will be compared for any entry that contains the matching URL. If the referrer matches, then the specified action will be performed by proxy.

### Configuring in the GUI

The configuration can be done in the GUI but only if advanced web filtering features have been enabled by entering the following commands in the CLI:

```
config system global
 set gui-webfilter-advanced enable
end
```

After this command is used, a new column will be created in **Security Profiles > Web Filter** to set the referrer.

## Configuring in the CLI

When specifying the URL filter, it needs to be identified by its ID. The URLs are listed under each entry.

To find the ID number:

```
config webfilter urlfilter
 edit ?
```

A list of the current URL filters will be listed with their ID numbers in the left column.

The syntax in the CLI for configuring an entry is:

```
config webfilter urlfilter
 edit <ID>
 config entries
 edit 1
 set url <url>
 set referrer-host <url>
 set type {simple | regex | wildcard}
 set action {block | allow | monitor | exempt}
 set status {enable | disable}
 end
 end
 end
```

## Web content filter

You can control web content by blocking access to web pages containing specific words or patterns. This helps to prevent access to pages with questionable material. You can also add words, phrases, patterns, wild cards and Perl regular expressions to match content on web pages. You can add multiple web content filter lists and then select the best web content filter list for each web filter profile.

Enabling web content filtering involves three separate parts of the FortiGate configuration.

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day.
- The web filter profile specifies what sort of web filtering is applied.
- The web content filter list contains blocked and exempt patterns.

The web content filter feature scans the content of every web page that is accepted by a security policy. The system administrator can specify banned words and phrases and attach a numerical value, or score, to the importance of those words and phrases. When the web content filter scan detects banned content, it adds the scores of banned words and phrases in the page. If the sum is higher than a threshold set in the web filter profile, the FortiGate unit blocks the page.

## General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a web content filter list.
2. Add patterns of words, phrases, wildcards, and regular expressions that match the content to be blocked or exempted.
3. You can add the patterns in any order to the list. You need to add at least one pattern that blocks content.
4. In a web filter profile, enable the web content filter and select a web content filter list from the options list.

To complete the configuration, you need to select a security policy or create a new one. Then, in the security policy, enable **Webfilter** and select the appropriate web filter profile from the list.

## Creating a web filter content list

You can create multiple content lists and then select the best one for each web filter profile. Creating your own web content lists can be accomplished only using the CLI.

This example shows how to create a web content list called inappropriate language, with two entries, offensive and rude.

### To create a web filter content list

```
config webfilter content
edit 3
 set name "inappropriate language"
 config entries
 edit offensive
 set action block
 set lang western
 set pattern-type wildcard
 set score 15
 set status enable
 next
 edit rude
 set action block
 set lang western
 set pattern-type wildcard
 set score 5
 set status enable
 end
 end
end
```

## Configuring a web content filter list

Once you have created the web filter content list, you need to add web content patterns to it. There are two types of patterns: **Wildcard** and **Regular Expression**.

You use the **Wildcard** setting to block or exempt one word or text strings of up to 80 characters. You can also use the wildcard symbols, such as "\*" or "?", to represent one or more characters. For example, as a wildcard expression, forti\*.com will match fortinet.com and forticare.com. The "\*" represents any kind of character appearing any number of times.

You use the **Regular Expression** setting to block or exempt patterns of Perl expressions, which use some of the same symbols as wildcard expressions, but for different purposes. The "\*" represents the character before the symbol. For example, forti\*.com will match fortiii.com but not fortinet.com or fortiice.com. The symbol "+" represents "+" in this case, appearing any number of times. RP: Add a regex example.

The maximum number of web content patterns in a list is 5000.

## How content is evaluated

Every time the web content filter detects banned content on a web page, it adds the score for that content to the sum of scores for that web page. You set this score when you create a new pattern to block the content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the sum of scores equals or exceeds the threshold score, the web page is blocked. The default score for web content filter is 10 and the default threshold is 10. This means that by default a web page is blocked by a single match. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

Banned words or phrases are evaluated according to the following rules:

- The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.
- The score for any word in a phrase without quotation marks is counted.
- The score for a phrase in quotation marks is counted only if it appears exactly as written.

The following table describes how these rules are applied to the contents of a web page. Consider the following, a web page that contains only this sentence: "The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page."

### Banned Pattern Rules

| Banned pattern          | Assigned score | Score added to the sum for the entire page | Threshold score | Comment                                                                                                                                                                     |
|-------------------------|----------------|--------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>word</b>             | 20             | 20                                         | 20              | Appears twice but only counted once. Web page is blocked.                                                                                                                   |
| <b>word phrase</b>      | 20             | 40                                         | 20              | Each word appears twice but only counted once giving a total score of 40. Web page is blocked                                                                               |
| <b>word sentence</b>    | 20             | 20                                         | 20              | "word" appears twice, "sentence" does not appear, but since any word in a phrase without quotation marks is counted, the score for this pattern is 20. Web page is blocked. |
| <b>"word sentence"</b>  | 20             | 0                                          | 20              | "This phrase does not appear exactly as written. Web page is allowed.                                                                                                       |
| <b>"word or phrase"</b> | 20             | 20                                         | 20              | This phrase appears twice but is counted only once. Web page is blocked.                                                                                                    |

## Enabling the web content filter and setting the content threshold

When you enable the web content filter, the web filter will block any web pages when the sum of scores for banned content on that page exceeds the content block threshold. The threshold will be disregarded for any exemptions within the web filter list.

## Web filtering example

Web filtering is particularly important for protecting school-aged children. There are legal issues associated with improper web filtering as well as a moral responsibility to keep children from viewing inappropriate material. The key is to design a web filtering system in such a way that students and staff do not fall under the same web filter profile in the FortiGate configuration. This is important because the staff may need to access websites that are off limits to the students.

### School district

The background for this scenario is a school district with more than 2,300 students and 500 faculty and staff in a preschool, three elementary schools, a middle school, a high school, and a continuing education center. Each elementary school has a computer lab and the high school has three computer labs with connections to the Internet. Such easy access to the Internet ensures that every student touches a computer every day.

With such a diverse group of Internet users, it was not possible for the school district to set different Internet access levels. This meant that faculty and staff were unable to view websites that the school district had blocked. Another issue was the students' use of proxy sites to circumvent the previous web filtering system. A proxy server acts as a go-between for users seeking to view web pages from another server. If the proxy server has not been blocked by the school district, the students can access the blocked website.

When determining what websites are appropriate for each school, the district examined a number of factors, such as community standards and different needs of each school based on the age of the students.

The district decided to configure the FortiGate web filtering options to block content of an inappropriate nature and to allow each individual school to modify the options to suit the age of the students. This way, each individual school was able to add or remove blocked sites almost immediately and have greater control over their students' Internet usage.

In this simplified example of the scenario, the district wants to block any websites with the word **example** on them, as well as the website [www.example.com](http://www.example.com). The first task is to create web content filter lists for the students and the teachers.

Web Filter in flow mode does not support Safe Search. The examples below use Web Filter in proxy mode.

---

### Create a Web Filter profile for the students

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name "Students" in the name field.
4. Enable FortiGuard Categories.
  - a. Set the following categories to **Block**:
    - Potentially Liable
    - Adult/Mature Content
    - Security Risk

### URL Content

6. Go to **Search Engines** and expand the section if necessary. Enable **Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex**
7. In the **Static URL Filter** section, enable **URL Filter**.
  - a. Select **Create New**.
    - i. In the **URL** field, enter \*example\*.\*
    - ii. For the **Type** field, select **Wildcard**
    - iii. For the **Action** field, select **Block**
    - iv. For the **Status** field, check **enable**
    - v. Select **OK**

#### Web Content Filter

8. In the **Static URL Filter** section, enable **Web Content Filter**.
  - a. In the **Web Content Filter** widget, select **Create New**.
    - i. For the **Pattern Type** field, select **Reg. Expression**
    - ii. In the **Pattern** field, enter "example"
    - iii. For the **Language** field, choose Western
    - iv. For the **Action** field, select "Block"
    - v. For the **Status** field, check Enable.
    - vi. Select **OK**
9. Enable **Rate URLs by Domain and IP Address**
10. Disable **Allow websites when a rating error occurs**.
11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **Apply**

#### Create a Web Filter for the teachers

It might be more efficient if the Teacher Web Content List included the same blocked content as the student list. From time to time a teacher might have to view a blocked page. It would then be a matter of changing the **Action** from **Block** to **Allow** as the situation required. The following filter is how it could be set up for the teachers to allow them to see the "example" content if needed while keeping the blocking inappropriate material condition.

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name "Teachers" in the name field.
4. Enable FortiGuard Categories.
  - a. Set the following categories to **Block**:
    - Potentially Liable
    - Adult/Mature Content
    - Security Risk

#### URL Content

6. Go to **Search Engines** and expand the section if necessary. Enable **Search Engine Safe Search on Google, Yahoo!, Bing, Yandex**.
7. In the **Static URL Filter** section, check **Enable URL Filter**.
  - a. Select **Create New**.

- i. In the **URL** field, enter \*example\*.\*
- ii. For the **Type** field, select **Wildcard**
- iii. For the **Action** field, select **Block**
- iv. For the **Status** field, check **enable**
- v. Select **OK**

#### **Web Content Filter**

8. In the Static URL Filter section, check **Enable Web Content Filter**.
  - a. In the Web Content Filter widget, select **Create New**.
  - b. Enter the name "Teachers" in the name field.
    - i. For the **Pattern Type** field, select **Reg. Expression**
    - ii. In the **Pattern** field, enter "example"
    - iii. For the **Language** field, choose **Western**
    - iv. For the **Action** field, select **Exempt**
    - v. For the **Status** field, check **Enable**.
    - vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
11. Select **OK**

#### **To create a security policy for the students**

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage student traffic.
3. Enable **Web Filter**.
4. Select **Students** from the web filter drop-down list.
5. Select **OK**.

#### **To create a security policy for Teachers**

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage teacher traffic.
3. Enable **Web Filter**.
4. Select **Teachers** from the web filter drop-down list.
5. Select **OK**.
6. Make sure that the student policy is in the sequence before the teachers' policy.

## **Advanced web filter configurations**

### **Allow websites when a rating error occurs**

Enable this setting to allow access to web pages that return a rating error from the FortiGuard Web Filter service.

If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines the type of access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.

### ActiveX filter

Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

### Block Invalid URLs

Select to block web sites when their SSL certificate CN field does not contain a valid domain name.

FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs:

- If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name.
- If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.

Enabling the Web Filter profile to block a particular category and enabling the Application Control profile will not result in blocking the URL. This occurs because proxy and flow-based profiles cannot operate together.

To ensure replacement messages show up for blocked URLs, switch the Web Filter to flow-based inspection.

---

### Cookie filter

Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.

### Provide Details for Blocked HTTP 4xx and 5xx Errors

Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to circumvent web filtering.

### HTTP POST action

Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server.

The available actions include:

### Comfort

Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic.

The client comforting settings used are those defined in the Proxy Options profile selected in the security policy.

## Block

Block the HTTP POST command. This will limit users from sending information and files to web sites.

When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.

## Java applet filter

Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.

## Rate Images by URL

Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category.

Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.

## Rate URLs by Domain and IP Address

Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter.

If the rating determined by the domain name and the rating determined by the IP address defer the Action that is enforce will be determined by a weighting assigned to the different categories. The higher weighted category will take precedence in determining the action. This will have the side effect that sometimes the Action will be determined by the classification based on the domain name and other times it will be determined by the classification that is based on the IP address.

FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.

---

An example of how this would work would be if a URL's rating based on the domain name indicated that it belonged in the category Lingerie and Swimsuit, which is allowed but the category assigned to the IP address was Pornography which has an action of Block, because the Pornography category has a higher weight the effective action is Block.

## Web resume download block

Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off.

This prevents the unintentional download of viruses hidden in fragmented files.

Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.

## Restrict Google account usage to specific domains

This feature allow the blocking of access to some Google accounts and services while allowing access to accounts that are included in the domains specified in the exception list.

## Block non-English character URLs

The FortiGate will not successfully block non-English character URLs if they are added to the URL filter. In order to block access to URLs with non-English characters, the characters must be translated into their international characters.

Browse to the non-English character URL (for example, <http://www.fortinet.com/pages/ที่'นี้'ไม่มีเครือข่ายประหารให้ใครแตก/338419686287505?ref=stream>).

On the FortiGate, use the URL shown in the FortiGate GUI and add it the list of blocked URLs in your URL filter (for example,

<http://www.fortinet.com/pages/%E0%B8%97%E0%B8%B5%E0%B9%88%E0%B8%99%E0%B8%B5%E0%B9%88-%E0%B9%84%E0%B8%A1%E0%B9%88%E0%B8%A1%E0%B8%B5%E0%B9%80%E0%B8%A8%E0%B8%A9%E0%B8%A3%E0%B8%B1%E0%B8%90%E0%B8%9B%E0%B8%A3%E0%B8%B0%E0%B8%AB%E0%B8%B2%E0%B8%A3%E0%B9%83%E0%B8%AB%E0%B9%89%E0%B9%83%E0%B8%84%E0%B8%A3%E0%B9%81%E0%B8%94%E0%B8%81/338419686287505?ref=stream>).

Once added, further browsing to the URL will result in a blocked page.

## CLI Syntax

```
config webfilter urlfilter
 edit 1
 set name "block_international_character_urls"
 config entries
 edit 1
 set url "www.fortinet.com/pages/2.710850E-3120%B8%E0%B8%B53.231533E-
 3170%B9%E0%B8%E0%B8%B53.231533E-3170%B9%88-3.230415E-
 3170%B9%E0%B8X0.000000063CD94P-102211.482197E-
 3230%B9%E0%B8X0.0007FBFFFFCFP-102210.000000E+000%B8%B51.828043E-
 3210%B9%E0%B8X0P+081.828043E-3210%B8X0P+092.710850E-

 3200%B9%E0%B8%E0%B8%81/338419686287505?ref=stream"
 set action block
 next
 end
 next
end

config webfilter urlfilter
 edit 2
 set name "block_international_character_urls"
 next
end

config webfilter profile
 edit "block_international_character_urls"
 next
```

```
end

config firewall policy
 edit 3
 set uuid cf80d386-7bcf-51e5-6e87-db207e3f0fa8
 set srcintf "port1"
 set dstintf "port2"
 set srcaddr "all"
 set dstaddr "all"
 set action accept
 set schedule "always"
 set service "ALL"
 set utm-status enable
 set logtraffic all
 set webfilter-profile "block_international_character_urls"
 set profile-protocol-options "default"
 set ssl-ssh-profile "certificate-inspection"
 set nat enable
 next
end
```

## Websense web filtering through WISP

WISP is a Websense protocol that allows for URLs to be extracted by a firewall and submitted to Websense systems for rating and approval checking.

This feature provides a solution for customers who have large, existing, deployed implementations of Websense security products to replace their legacy firewalls with a FortiGate family, such that they are not forced to make a change to their web filtering infrastructure at the same time.

When WISP is enabled, the FortiGate will maintain a pool of TCP connections to the WISP server. The TCP connections will be used to forward HTTP request information and log information to the WISP server and receive policy decisions.

## Configuring the WISP server

In order to use WebSense's web filtering service, a WISP server per VDOM must be defined and enabled first.

```
config web-proxy wisp
 edit {name}
 # Configure Wireless Internet service provider (WISP) servers.
 set name {string} Server name. size[35]
 set comment {string} Comment. size[255]
 set outgoing-ip {ipv4 address any} WISP outgoing IP address.
 set server-ip {ipv4 address any} WISP server IP address.
 set server-port {integer} WISP server port (1 - 65535, default = 15868). range[1-65535]
 set max-connections {integer} Maximum number of web proxy WISP connections (4 - 4096, default =
64). range[4-4096]
 set timeout {integer} Period of time before WISP requests time out (1 - 15 sec, default = 5). range
[1-15]
 next
end
```

## Example configuration

```
config web-proxy wisp
```

```
edit 0
 set outgoing-ip 0.0.0.0
 set server-ip 0.0.0.0
 set server-port 15868
 set max-connections 64
 set timeout 5
next
end
```

After configuring the WISP server, enable WISP in the web filter profile.

```
config webfilter profile
 edit "wisp_only"
 set wisp enable
 set wisp-servers 0
 next
end
```

Now you can apply the web filter profile to a firewall policy.

If you configure more than one WISP server, the load balance option can also be configured.

```
config webfilter profile
 edit "wisp_only"
 set wisp-algorithm {primary-secondary | round-robin | auto-learning}
 next
end
```

The options for the `wisp-algorithm` are:

- `primary-secondary`: select the first healthy server in order
- `round-robin`: select the next healthy server
- `auto-learning` select the lightest loading healthy server

## DNS Filter

You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to **block**, the result of the DNS lookup is not returned to the requester. If the category is set to **redirect**, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow or monitor access based on FortiGuard category.

### Blocking DNS requests to known botnet command & control addresses

FortiGuard maintains a database containing a list of known botnet command and control (C&C) addresses. This database is updated dynamically and stored on the FortiGate and requires a valid FortiGuard AntiVirus subscription.

When you block DNS requests to known botnet C&C addresses, using IPS, DNS lookups are checked against the botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable this feature, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**.

### Static Domain Filter

The DNS **Static Domain Filter** allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

### CLI commands

#### Configure DNS URL filter:

```
config dnsfilter urlfilter
 edit 1
 set name "url1"
 set comment ''
 config entries
 edit 1
 set url "www.google.com"
 set type simple
 set action block
 set status enable
 next
 edit 2
 set url "www.yahoo.com"
 set type simple
 set action monitor
 set status enable
 next
 edit 3
 set url "www.foritnet.com"
 set type simple
 set action allow
 set status enable
 next
 end
 next
end
```

#### Configure DNS filter profile:

```
config dnsfilter profile
 edit "dns_profile1"
 set comment ''
 config urlfilter
 set urlfilter-table 1
 end
```

```

config ftgd-dns
 config filters
 edit 1
 set category 49
 set action block
 set log enable
 next
 edit 2
 set category 71
 set action monitor
 set log enable
 next
 end
 set log-all-url disable
 set block-action redirect
 set redirect-portal 0.0.0.0
 set block-botnet enable
next
end

```

### Configure DNS profile in a firewall policy:

```

config firewall policy
 edit 1
 set srcintf "any"
 set dstintf "any"
 set srcaddr "all"
 set dstaddr "all"
 set action accept
 set schedule "always"
 set service "FTP"
 set utm-status enable
 set dnsfilter-profile "dns_profile1"
 set profile-protocol-options "default"
 set nat enable
 next
end

```

### Configure DNS profile in profile group:

```

config firewall profile-group
 edit "pgrp1"
 set dnsfilter-profile "dns_profile1"
 set profile-protocol-options "default"
 next
end

```

## DNS profile supports safe search

With the release of FortiOS 5.6, users can take advantage of pre-defined DNS filter rules to edit DNS profiles and provide safe search for Google, Bing, and YouTube.

### To add safe search to a DNS profile - GUI

1. Go to **Security Profiles > DNS Filter**.
2. Edit the default filter or create a new one.
3. Enable **Enforce 'Safe Search on Google, Bing, YouTube**.
4. Select **Strict** or **Moderate** level of restriction for **YouTube Access**.

### To add safe search to a DNS profile - CLI

```
config dnsfilter profile
 edit "default"
 set safe-search enable
 set youtube-restrict {strict | moderate} (only available is safe-search enabled)
 next
end
```

## FortiGuard Botnet protection

Preventing botnets from controlling your system is achieved by detecting and blocking connection attempts to known botnets. This feature also blocks connections to known phishing sites. The FortiGuard database is continually updated with addresses of known Command and Control (C&C) sites that botnet clients attempt to connect to, as well as addresses of known phishing URLs.

To enable botnet and phishing protection in a DNS Filter profile, enable **Block DNS requests to known botnet C&C**.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > AntiVirus >** and you will see data for **Botnet IPs** and **Botnet Domains**. You can also block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

Both the DNS Filter security profile and Botnet protection features available for both proxy-based and flow-based inspection modes.

---

## Application Control

Using the Application Control Security Profiles feature, your FortiGate unit can detect and take action against network traffic depending on the application generating the traffic. Based on FortiGate Intrusion Protection protocol decoders, application control is a user-friendly and powerful way to use Intrusion Protection features to log and manage the behavior of application traffic passing through the FortiGate unit. Application control uses IPS protocol decoders that can analyze network traffic to detect application traffic even if the traffic uses non-standard ports or protocols. Application control supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

The FortiGate unit can recognize the network traffic generated by a large number of applications. You can create application control sensors that specify the action to take with the traffic of the applications you need to manage and the network on which they are active, and then add application control sensors to the firewall policies that control the network traffic you need to monitor.

Fortinet is constantly adding to the list of applications detected through maintenance of the FortiGuard Application Control Database. This database is part of the FortiGuard Intrusion Protection System Database because intrusion protection protocol decoders are used for application control and both of these databases have the same version number.

**Cloud Access Security Inspection (CASI)** is merged with Application Control resulting in [changes to the GUI and the CLI](#).

You can identify the version of the application control database installed on your unit by going to the **Licenses** widget on the **Dashboard** and hovering over the **IPS & Application Control** line; the status, expiry date, and version will be displayed. Additionally, you can see the complete list of applications supported by FortiGuard Application Control on the [FortiGuard](#) site or <http://fortiguard.com/appcontrol>. This web page lists all of the supported applications. You can select any application name to see details about the application.

Application Control is now a standard part of any FortiCare support contract and the database for Application Control signatures is separate from the IPS database. However, Botnet application signatures are still part of the IPS signature database since these are more closely related with security issues and less about application detection.

---

If you enable virtual domains (VDOMs) on the Fortinet unit, you must configure application control separately for each virtual domain.

This Handbook chapter includes [Inside FortiOS: Application Control](#) and provides readers an overview of the features and benefits of key FortiOS 5.6 components. For readers needing to delve into greater detail, we provide the following topics:

## Application control concepts

You can control network traffic generally by the source or destination address, or by the port, the quantity or similar attributes of the traffic itself in the security policy. If you want to control the flow of traffic from a specific application, these methods may not be sufficient to precisely define the traffic. To address this problem, the application control feature examines the traffic itself for signatures unique to the application generating it.

Application control does not require knowledge of any server addresses or ports. The FortiGate unit includes signatures for over 2,000 applications, services, and protocols.

Updated and new application signatures are delivered to your FortiGate unit as part of your FortiGuard Application Control Service subscription, which is a free service. Fortinet is constantly increasing the number of applications that this feature can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database. Both of these databases have the same version number.

You can find the version of the application control database installed on your unit by going to the **Licenses** widget on the **Dashboard** and hovering over the **IPS& Application Control** line; the status, expiry date, and version will be displayed.

To see the complete list of applications supported by FortiGuard Application Control go to the [FortiGuard](http://fortiguard.com/appcontrol) site or <http://fortiguard.com/appcontrol>. This web page lists all of the supported applications. You can select any application name to see details about the application.

## Cloud Access Security Inspection (CASI)

The Cloud Access Security Inspection (CASI) feature is now merged with Application Control resulting in changes to the GUI and the CLI.

### GUI Changes

- Toggle option added to quickly filter CASI signatures in the Application Signatures list.
- Application Overrides table now shows any parent-child hierarchy using the --parent metadata on signatures. Deleting a parent app also deletes its child apps. And conversely, adding a child app will add all its parent apps but with implicit filter action.
- A policy breakdown is shown on existing application control profiles for policies using the profile. The breakdown indicates which policies are using a deep inspection.
- A breakdown is shown for application categories and filter overrides to indicate the number of CASI and non-CASI signatures. A lock icon is shown for applications requiring deep inspection.

### CLI Changes

Commands removed:

- `config application casi profile`
- `casi profile in config firewall policy`
- `casi profile in config firewall policy6`
- `casi-profile-status` and `casi-profile` under `config firewall sniffer`
- `casi-profile-status` and `casi-profile` under `config firewall interface-policy`

## Enabling application control in profile-based modes

Application control examines your network traffic for traffic generated by the applications you want it to control. The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

## General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an application sensor.
2. Configure the sensor to include the signatures for the application traffic you want the FortiGate unit to detect.
3. Enable any other applicable options.
4. Enable application control in a security policy and select the application sensor.

## Creating an application sensor

You need to create an application sensor before you can enable application control.

### To create an application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter the name of the new application sensor.
4. Optionally, enter descriptive **Comments**.

## Adding applications to an application sensor

Once you have created an application sensor, you need to need to define the applications that you want to control. You can add applications and filters using categories, application overrides, and/or filter overrides. Categories will allow you to choose groups of signatures based on a category type. Application overrides allow you to choose individual applications. Filter overrides allow you to select groups of applications and override the application signature settings for them.

### To add a category of signatures to the sensor.

1. Go to **Security Profiles > Application Control**.
2. Under **Categories**, you may select from the following:
  - Business
  - Cloud.IT
  - Collaboration
  - Email
  - Game
  - General.Interest
  - Industrial
  - Mobile
  - Network.Service
  - P2P
  - Proxy
  - Remote.Access
  - Social.Media
  - Storage.Backup
  - Update

- Video/Audio
- VoIP
- Web.Client
- Unknown Applications

When selecting the category that you intend to work with, left click on the icon next to the category name to see a drop down menu that includes these actions:

- Allow
- Monitor
- Block
- Quarantine
- View Signatures

These actions are briefly defined under [Application Control actions on page 2864](#).

3. If you wish to add individual applications, select **Add Signatures** under **Application Overrides**.
  - a. Use the **Add Filter** search field to narrow down the list of possible signatures by a series of attributes.
  - b. When finished, select **Use Selected Signatures**.
4. If you wish to add advanced filters, select **Add Filter** under **Filter Overrides**.
  - a. Use the Add Filter search field to narrow down the list of possible filters by a series of attributes.
  - b. When finished, select **Use Filters**.
4. Select, if applicable, from the following options:
  - **Allow and Log DNS Traffic**
  - **Replacement Messages for HTTP-based Applications**
6. Select **OK**.

### Applying the application sensor to a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

#### To select the application sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Click the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to enable the feature.
5. In the drop down menu field next to the **Application Control** select the application sensor you wish to apply to the policy.
6. Select **OK**.

### Creating a new custom application signature

If you have to deal with an application that is not already in the **Application List** you have the option to create a new application signature.

1. Go to **Security Profiles > Application Control**.
2. Select the link in the upper right corner, **[View Application Signatures]**
3. Select the **Create New** icon
4. Give the new signature a name (no spaces) in the **Name** field.
5. Enter a brief description in the **Comments** field
6. Enter the text for the signature in the signature field. Use the rules found under [Custom IPS signature](#) to determine syntax.
7. Select **OK**.

You can configure rate based application control signatures in the CLI Console using similar IPS signature rate CLI commands.

For more information on this and the CLI syntax, see [IPS signature rate count threshold on page 2880](#)

## Messages in response to blocked applications

Once an Application Control sensor has been configured to block a specified application and applied to a policy it would seem inevitable that at some point an application will end up getting blocked, even if it is only to test the functionality of the control. When this happens, the sensor can be set to either display a message to offending user or to just block without any notification. The default setting is to display a message. Setting this up is done in the CLI.

```
config application list
 edit <name of the sensor>
 set app-replacemsg {enable | disable}
 end
```

When blocking applications, there is no replacement message for SSL traffic with certificate inspection applied.

When SSL deep inspection is enabled, a replacement message will appear depending on the protocol. For example, with HTTP2, the blocking is done in the SSL key exchange once the first server packet is delivered and replacement messages can not be displayed.

## P2P application detection

P2P software tends to be evasive. You may be able to enhance P2P application detection by matching patterns found in the most recent three minutes of P2P traffic to determine if new traffic is P2P. Three minutes is the length of time information about matched P2P traffic remains in shared memory.

For example, the CLI commands below will result in the Intrusion Prevention System (IPS) looking for patterns formed by Skype traffic.

```
config application list
 edit <app_list_str>
 set p2p-black-list skype
 end
end
```

## Application Control actions

### Allow

This action allows the targeted traffic to continue on through the FortiGate unit.

### Monitor

This action allows the targeted traffic to continue on through the FortiGate unit but logs the traffic for analysis.

### Block

This action prevents all traffic from reaching the application and logs all occurrences.

### Quarantine

This action allows you to quarantine or block access to an application for a specified duration that can be entered in days, hours, and minutes. The default is 5 minutes.

### View Signatures

This option brings up a window that displays a list of the signatures with the following columns:

- Name
- Category
- Technology - Technology is broken down into 3 technology models as well as the more basic Network-Protocol which would can be used as a catch all for anything not covered by the more narrowly defined technologies of:
  - Browser-Based
  - Client-Server
  - Peer-to-Peer
- Popularity - Popularity is broken down into 5 levels of popularity represented by stars.
- Risk - The Risk property does not indicate the level of risk but the type of impact that is likely to occur by allowing the traffic from that application to occur.

### Traffic Shaping

Prior to the release of FortiOS 5.4.0, application control traffic shaping was configured in the **Security Profiles > Application Control** interface. There is now a specific section for traffic shaping policies in **Policy & Objects > Traffic Shaping Policy**. See [Traffic shaping methods](#) in the chapter on Traffic Shaping for details

## Application considerations

Some applications behave differently from most others. You should be aware of these differences before using application control to regulate their use.

### IM applications

IM applications are controlled by either permitting or denying the users from logging in to the service. Individual IM accounts are configured as to whether or not they are permitted and then there is a global policy for how to

action unknown users, by the application and whether to add the user to the black list or the white list. IM applications fall under the **Collaboration** category in the application signature database.

## Skype

Based on the NAT firewall type, Skype takes advantage of several NAT firewall traversal methods, such as STUN (Simple Traversal of UDP through NAT), ICE (Interactive Connectivity Establishment) and TURN (Traversal Using Relay NAT), to make the connection.

The Skype client may try to log in with either UDP or TCP, on different ports, especially well-known service ports, such as HTTP (80) and HTTPS (443), because these ports are normally allowed in firewall settings. A client who has previously logged in successfully could start with the known good approach, then fall back on another approach if the known one fails.

The Skype client could also employ Connection Relay. This means if a reachable host is already connected to the Skype network, other clients can connect through this host. This makes any connected host not only a client but also a relay server.

## SPDY

SPDY (pronounced speedy, it's a trademarked name not an acronym) is a networking protocol developed to increase the speed and security of HTML traffic. It was developed primarily by Google. The Application Control engine recognizes this protocol and its required SSL/TLS component within Application Control sensors. It is counted as part of application traffic for Google and other sources that use the protocol.

## Application control monitor

The application monitor enables you to gain insight into the applications generating traffic on your network. When monitor is enabled in an application sensor entry and that security profile is selected in a security policy, all the detected traffic required to populate the selected charts is logged to the SQL database on the FortiGate unit hard drive. The charts are available for display in the **Applications** section of the **FortiView** menu.

Because the application monitor relies on an SQL database, the feature is available only on FortiGate units with an internal hard drive.

---

Application monitor data is stored on the hard drive and restarting the system does not affect the stored monitor data.

Application control data is available in **Log & Report**, if enabled.

## Application control examples

The scenarios below provide a better understanding of how to implement Application Control and give some ideas as to why it would be used.

- [Blocking instant messaging](#)
- [Allowing only software updates](#)
- [Blocking Windows XP with a custom signature](#)

## Blocking instant messaging

Instant messaging use is not permitted at the Example Corporation. Application control helps enforce this policy.

The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

### Steps in this process

1. First you will create an application sensor with a single entry that monitors the category that includes instant messaging applications. You will set the list action to **Monitor**.
2. Next you will assign the sensor to a policy.
3. Then you will identify the IM applications being used on your network and modify the application sensor to **Block** use of those messaging applications

### To create the application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `no_IM` for the application sensor name.
4. If the **Collaboration** category is not already set to **Monitor**, then left-click on the icon next to that category and select **Monitor** from the dropdown menu.
5. Select **OK** to save the new sensor.

### To enable application control and select the application sensor

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows the network users to access the Internet and choose **Edit**.
3. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
4. In the drop down menu field next to the **Application Control** select the `no_IM` application sensor.
5. To inspect all traffic, **SSL/SSH inspection** must be set to **deep-inspection** profile.
6. Select **OK**.

### To identify IM applications in use on your network

1. Go to **FortiView > Applications**.
2. Select a time period from the options in the upper-right corner of the window and examine the list of applications.
3. Identify any IM applications you wish to block.

### To block IM applications in use on your network

1. Go to **Security Profiles > Application Control** and edit the `no_IM` application sensor.
2. Under **Application Overrides**, click on **Add Signatures**.
3. Filter by **Name** and select the IM applications you wish to block.
4. Click on **Use Selected Signatures**.

The selected application will appear under **Application Overrides** and the action will be set to **Block**.

5. Select **Apply**.

The IM applications identified will be blocked by the security policy that has the **no IM** application sensor applied to it. If other firewall policies handle traffic that users could use for applications in the same category, enable application control with the **no IM** application sensor for those policies as well.

## Allowing only software updates

Some departments at Example Corporation do not require access to the Internet to perform their duties. Management therefore decided to block their Internet access. Software updates quickly became an issue because automatic updates will not function without Internet access and manual application of updates is time-consuming.

The solution is configuring application control to allow only automatic software updates to access the Internet.

The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

### To create an application sensor — GUI

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `Updates_Only` as the application sensor name.
4. Using the left-click and drop down on the items in the **Category** list.
  - a. Select **Monitor** from the dropdown menu.
  - b. Select **Block** for the rest of the categories.
5. Select **OK**.

### To create an application sensor — CLI

```
config application list
 edit Updates_Only
 config entries
 edit 1
 set category 17
 set action pass
 end
 set other-application-action block
 set unknown-application-action block
 end
 end
```

You will notice that there are some differences in the naming convention between the GUI and the CLI. For instance the **Action** in the CLI is “`pass`” and the **Action** in the GUI is “**Monitor**”.

## Selecting the application sensor in a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

**To select the application sensor in a security policy — GUI**

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
5. In the drop down menu field next to the **Application Control** select the `Updates_only` list.
6. Select **OK**.

**To select the application sensor in a security policy — CLI**

```
config firewall policy
 edit 1
 set utm-status enable
 set profile-protocol-options default
 set application-list Updates_Only
 end
```

Traffic handled by the security policy you modified will be scanned for application traffic. Software updates are permitted and all other application traffic is blocked.

**Blocking Windows XP with a custom signature**

In this example, you will use application control to block web traffic from PCs running Windows operating systems NT 5, including Windows XP and Windows Server 2003 (includes Windows virtual machines).

When a computer's operating system lacks vendor support, it becomes a threat to the network because newly discovered exploits will not be patched. Using the FortiGate application control feature, you can restrict these computers from accessing external resources.

This example will only block web traffic from computers running the affected operating systems. If you wish to block these computers from being on the network entirely, further action will be necessary. However, the logs generated can be used to identify the computers you wish to block.

1. Go to **System > Feature Select**. Enable **Application Control** and **Apply** your changes.
2. Go to **Security Profiles > Application Control** and select **View Application Signatures**.
3. Create a new signature with the syntax below. You can copy and paste the text into the **Signature** field. Name the signature *Block-Windows-NT5*.

```
F-SBID(--attack_id 8055;--vuln_id 8055;--name
"Windows.NT.5.Web.Surfing";--flow from_client;--pattern !"FCT";--
pattern "Windows NT 5.";--no_case;--context header;--weight 40;--
service HTTP;--protocol tcp;--app_cat 25;--default_action drop_
session;)
```

If you do not include keyword / value pairs for `--attack_id` or `--vuln_ID` in the signature, the FortiGate will automatically assign values.

The signature will appear at the top of the application list and be listed in the **Web.Client** category.

4. Go to **Security Profiles > Application Control** and edit the **default** policy.
5. Under **Application Overrides**, select **Add Signatures**. The new signature should appear at the top of the list. If it does not, search for the signature's name.
6. Select the signature, then select **Use Selected Signatures**.

7. Go to **Policy & Objects > IPv4 Policy** and edit the policy that allows connections from the internal network to the Internet.
8. Under **Security Profiles**, turn on **Application Control** and use the **default** profile.

## Results

When a PC running one of the affected operating systems attempts to connect to the Internet using a browser, a blocked message appears. Because Application Control uses flow-based inspection, if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the replacement message. However, Application Control will still function.

PCs running other operating systems, including later versions of Windows, are not affected.

Go to **FortiView > All Sessions** and select the **5 minutes** view.

Filter the results to show sessions that were blocked.

You will see that the Application Control signature, shown in the **Application Name** column, was used to block traffic from PCs running older Windows versions.

For further reading, see [Custom Application & IPS Signatures](#).

## Intrusion prevention

The FortiOS Intrusion Prevention System (IPS) combines signature detection and prevention with low latency and excellent reliability. With intrusion protection, you can create multiple IPS sensors, each containing a complete configuration based on signatures. Then, you can apply any IPS sensor to any security policy.

This section describes how to configure the FortiOS Intrusion Prevention settings.

If you enable virtual domains (VDOMs) on the FortiGate unit, intrusion prevention is configured separately for each virtual domain.

This Handbook chapter includes [Inside FortiOS: Intrusion Prevention System](#) providing readers an overview of the features and benefits of key FortiOS 5.6 components. For readers needing to delve into greater detail, we provide the following:

## IPS concepts

The FortiOS Intrusion Prevention System (IPS) protects your network from outside attacks. Your FortiGate unit has two techniques to deal with these attacks: anomaly- and signature-based defense.

### Anomaly-based defense

Anomaly-based defense is used when network traffic itself is used as a weapon. A host can be flooded with far more traffic than it can handle, making the host inaccessible. The most common example is the denial of service (DoS) attack, in which an attacker directs a large number of computers to attempt normal access of the target system. If enough access attempts are made, the target is overwhelmed and unable to service genuine users. The attacker does not gain access to the target system, but it is not accessible to anyone else.

The FortiGate DoS feature will block traffic above a certain threshold from the attacker and allow connections from other legitimate users. The DoS policy configuration can be found in the Firewall chapter of the Handbook.

### Access control lists in DoS Policies

This feature allows you to define a list of IPs/subnets/ranges in a DoS policy, and block those IPs from sending any traffic, by way of an ACL (access control list). The ACL looks similar to a firewall policy, but only checks source IP, destination IP, destination port, and protocol. To configure in the GUI, go to **Policy & Objects > IPv4 Access Control List** and create a new policy. Enter the incoming interface, the source address, the destination address, the services impacted, and, optionally, enter a comment.

### CLI Syntax

```
config firewall acl
 edit 1
 set interface "port1"
 set srcaddr "google-drive"
 set dstaddr "all"
 set service "ALL"
 next
end
```

## Signature-based defense

Signature-based defense is used against known attacks or vulnerability exploits. These often involve an attacker attempting to gain access to your network. The attacker must communicate with the host in an attempt to gain access and this communication will include particular commands or sequences of commands and variables. The IPS signatures include these command sequences, allowing the FortiGate unit to detect and stop the attack.

### Signatures

IPS signatures are the basis of signature-based intrusion prevention. Every attack can be reduced to a particular string of commands or a sequence of commands and variables. Signatures include this information so your FortiGate unit knows what to look for in network traffic.

Signatures also include characteristics about the attack they describe. These characteristics include the network protocol in which the attack will appear, the vulnerable operating system, and the vulnerable application.

To view the complete list of signatures, go to **Security Profiles > Intrusion Prevention**, and select **View IPS Signatures**. This will include the predefined signatures and any custom signatures that you may have created.

With the release of FortiOS 5.6, the IPS signatures list page shows which IPS package is currently deployed. Users can also change their IPS package by hovering over the information icon next to the IPS package name. Text will appear that links directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

### Protocol decoders

Before examining network traffic for attacks, the IPS engine uses protocol decoders to identify each protocol appearing in the traffic. Attacks are protocol-specific, so your FortiGate unit conserves resources by looking for attacks only in the protocols used to transmit them. For example, the FortiGate unit will only examine HTTP traffic for the presence of a signature describing an HTTP attack.

### IPS engine

Once the protocol decoders separate the network traffic by protocol, the IPS engine examines the network traffic for the attack signatures.

### IPS sensors

The IPS engine does not examine network traffic for all signatures. You must first create an IPS sensor and specify which signatures are included. Add signatures to sensors individually using signature entries, or in groups using IPS filters.

To view the IPS sensors, go to **Security Profiles > Intrusion Prevention**.

You can group signatures into IPS sensors for easy selection when applying to firewall policies. You can define signatures for specific types of traffic in separate IPS sensors, and then select those sensors in profiles designed to handle that type of traffic. For example, you can specify all of the web-server related signatures in an IPS sensor, and that sensor can then be applied to a firewall policy that controls all of the traffic to and from a web server protected by the unit.

The FortiGuard Service periodically updates the pre-defined signatures, with signatures added to counter new threats. Since the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a

filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

Each IPS sensor consists of two parts: filters and overrides. Overrides are always checked before filters.

Each filter consists of a number of signature attributes. All of the signatures with those attributes, and only those attributes, are checked against traffic when the filter is run. If multiple filters are defined in an IPS Sensor, they are checked against the traffic one at a time, from top to bottom. If a match is found, the unit takes the appropriate action and stops further checking.

A signature override can modify the behavior of a signature specified in a filter. A signature override can also add a signature not specified in the sensor's filters. Custom signatures are included in an IPS sensor using overrides.

The signatures in the overrides are first compared to network traffic. If the IPS sensor does not find any matches, it then compares the signatures in each filter to network traffic, one filter at a time, from top to bottom. If no signature matches are found, the IPS sensor allows the network traffic.

The signatures included in the filter are only those matching every attribute specified. When created, a new filter has every attribute set to **all** which causes every signature to be included in the filter. If the severity is changed to high, and the target is changed to server, the filter includes only signatures checking for high priority attacks targeted at servers.

## IPS filters

IPS sensors contain one or more IPS filters. A filter is a collection of signature attributes that you specify. The signatures that have all of the attributes specified in a filter are included in the IPS filter.

For example, if your FortiGate unit protects a Linux server running the Apache web server software, you could create a new filter to protect it. By setting **OS** to **Linux**, and **Application** to **Apache**, the filter will include only the signatures that apply to both Linux and Apache. If you wanted to scan for all the Linux signatures and all the Apache signatures, you would create two filters, one for each.

To view the filters in an IPS sensor, go to **Security Profiles > Intrusion Prevention**, select the IPS sensor containing the filters you want to view, and select **Edit**.

## Custom/predefined signature entries

Signature entries allow you to add an individual custom or predefined IPS signature. If you need only one signature, adding a signature entry to an IPS sensor is the easiest way. Signature entries are also the only way to include custom signatures in an IPS sensor.

Another use for signature entries is to change the settings of individual signatures that are already included in a filter within the same IPS sensor. Add a signature entry with the required settings above the filter, and the signature entry will take priority.

## Policies

To use an IPS sensor, you must select it in a security policy or an interface policy. An IPS sensor that is not selected in a policy will have no effect on network traffic.

IPS is most often configured as part of a security policy. Unless stated otherwise, discussion of IPS sensor use will be in regards to firewall policies in this document.

## Session timers for IPS sessions

A session time-to-live (TTL) timer for IPS sessions is available to reduce synchronization problems between the FortiOS Kernel and IPS, and to reduce IPS memory usage. The timeout values can be customized.

## Enabling IPS scanning

Enabling IPS scanning involves two separate features of FortiOS 5.6:

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day. Firewall policies can also be used to deny traffic, but those policies do not apply to IPS scanning.
- The IPS sensor contains filters, signature entries, or both. These specify which signatures are included in the IPS sensor.

When IPS is enabled and an IPS sensor is selected in a security policy, and all network traffic matching the policy will be checked for the signatures in the IPS sensor.

## General configuration steps

For best results in configuring IPS scanning, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an IPS sensor.
2. Add signatures and /or filters.  
These can be:
  - Pattern based
  - Rate based
  - Customized
3. Optionally enable blocking malicious URLs.
4. Optionally enable Botnet C&C protection.
5. Select a security policy or create a new one.
6. In the security policy, turn on **IPS**, and choose the IPS sensor from the list.

All the network traffic controlled by this security policy will be processed according to the settings in the policy. These settings include the IPS sensor you specify in the policy.

## Creating an IPS sensor

You need to create an IPS sensor before specific signatures or filters can be chosen. The signatures can be added to a new sensor before it is saved. However, it is good practice to keep in mind that the sensor and its included filters are separate things, and that they are created separately.

### To create a new IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the **Create New** icon in the top of the Edit IPS Sensor window.
3. Enter the name of the new IPS sensor.
4. Optionally, enter a comment. The comment will appear in the IPS sensor list.
5. Optionally enable **Block malicious URLs** and set **Botnet C&C** protection to **Block** or **Monitor**.
6. Select **OK**.

A newly created sensor is empty and contains no filters or signatures. You need to add one or more filters or signatures before the sensor will be of any use.

## Blocking Malicious URLs

To use this IPS signature to block malicious URLs, select **Block malicious URLs**. This feature uses a local malicious URL database on the FortiGate to assist in drive-by exploits detection. The database contains all malicious URLs active in the last one month, and all drive-by exploit URLs active in the last three months. The number of URLs controlled are in the one million range.

## Adding IPS signatures to a sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the IPS sensor to which you want to add the signature using the drop-down list in the top row of the Edit IPS Sensor window or by going to the list window.
3. Under **IPS Signatures**, select **Add Signatures**.
4. Select one or more signatures from the list and select **Use Selected Signatures** to add them to the sensor.
5. Optionally right-click on each signature to change the **Action** (**Pass**, **Monitor**, **Block**, **Reset**, **Default** or **Quarantine**) and enable or disable **Packet Logging**.

## Adding an IPS filter to a sensor

While individual signatures can be added to a sensor, a filter allows you to add multiple signatures to a sensor by specifying the characteristics of the signatures to be added.

### To create a new Pattern Based Signature and Filter

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the IPS sensor to which you want to add the filter using the drop-down list in the top row of the Edit IPS Sensor window or by going to the list window.
3. Under **IPS Filters**, select **Add Filter**.
4. Configure the filter that you require. Signatures matching all of the characteristics you specify in the filter will be included in the filter. Once finished, select **Use Filters**.

**Application** refers to the application affected by the attack and filter options include over 25 applications.

**OS** refers to the Operating System affected by the attack. The options include **BSD**, **Linux**, **MacOS**, **Other**, **Solaris**, and **Windows**.

**Protocol** refers to the protocol that is the vector for the attack; filter options include over 35 protocols, including "other."

**Severity** refers to the level of threat posed by the attack. The options include **Critical**, **High**, **Medium**, **Low**, and **Info**.

**Target** refers to the type of device targeted by the attack. The options include **client** and **server**.

5. Once you have selected the filters you wish to add, right-click the filters and choose an action for when a signature is triggered:

| Action                | Description                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Pass</b>           | Select <b>Pass</b> to allow traffic to continue to its destination.<br><br><b>Note:</b> to see what the default for a signature is, go to the <b>IPS Signatures</b> page and enable the column <b>Action</b> , then find the row with the signature name in it.                                                            |
| <b>Monitor</b>        | Select <b>Monitor</b> to allow traffic to continue to its destination and log the activity. The log will appear under Log & Report but will only be visible in the GUI in the event of an intrusion.                                                                                                                       |
| <b>Block</b>          | Select <b>Block</b> to drop traffic matching any the signatures included in the filter.                                                                                                                                                                                                                                    |
| <b>Reset</b>          | Select <b>Reset</b> to reset the session whenever the signature is triggered. In the CLI this action is referred to as Reject.                                                                                                                                                                                             |
| <b>Default</b>        | Select <b>Default</b> to use the default action of the signature.                                                                                                                                                                                                                                                          |
| <b>Quarantine</b>     | The quarantine based on the attacker's IP Address - Traffic from the Attacker's IP address is refused until the expiration time from the trigger is reached. You may set the <b>Quarantine Duration</b> to any number of <b>Days, Hours, or Minutes</b> .                                                                  |
| <b>Packet Logging</b> | Select to enable packet logging for the filter.<br><br>When you enable packet logging on a filter, the unit saves a copy of the packets that match any signatures included in the filter. The packets can be analyzed later.<br><br>For more information about packet filtering, see "Configuring packet logging options". |

#### 6. Select **Apply**.

The filter is created and added to the filter list.

### Adding Rate Based Signatures

These are a subset of the signatures that are found in the database that are normally set to monitor. This group of signatures is for vulnerabilities that are normally only considered a serious threat when the targeted connections come in multiples, a little like DoS attacks.

Adding a rate based signature is straight forward. Select the enable button in the Rate Based Signature table that corresponds with the desired signature.

### Customized signatures

Customized signatures must be created before they can be added to the sensor. To get more details on customized signatures check the [Custom Application & IPS Signatures](#) chapter.

### Botnet C&C protection

You can set **Botnet C&C** protection to **Block** outgoing connections to Botnet sites or just record log messages (**Monitor**) when an outgoing Botnet connection attempt is detected.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard** and view the lists for Botnet IPs and Botnet Domains. You can look up more details about Botnet IPs and Domains on the FortiGuard site.

## Updating predefined IPS signatures

The FortiGuard Service periodically updates the predefined signatures and adds new signatures to counter emerging threats as they appear.

To ensure that your system is providing the most protection available, these updates can be scheduled as often as on an hourly basis. To configure this feature, go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**. From here you can set the updates to occur on a consistent weekly, daily, or even hourly basis.

Because the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

## Viewing and searching predefined IPS signatures

Go to **Security Profiles > Intrusion Prevention**. Select **[View IPS Signatures]** to view the list of existing IPS signatures. You may find signatures by paging manually through the list, apply filters, or by using the search field.

### Searching manually

Signatures are displayed in a paged list, with 50 signatures per page. The bottom of the screen shows the current page and the total number of pages. You can enter a page number and press enter, to skip directly to that page. Previous Page and Next Page buttons move you through the list, one page at a time. The First Page and Last Page button take you to the beginning or end of the list.

### Searching CVE-IDs

A **CVE-ID** column displaying CVE-IDs can be optionally added to the IPS Signatures list, however the column is only available if the IPS package contains CVE-IDs for signatures. CVE-IDs can be numerically filtered by selecting the CVE-ID column's arrows.

### Applying filters

You can enter criteria for one of more columns, and only the signatures matching all the conditions you specify will be listed.

#### To apply filters

1. Go to **Security Profiles > Intrusion Prevention**. Select **[View IPS Signatures]**.
2. Select column by which to filter.
3. Select the funnel/filter icon and enter the value or values to filter by.
4. Use additional columns as needed to refine search.

The available options vary by column. For example, **Enable** allows you to choose between two options, while OS has multiple options, and you may select multiple items together. Filtering by name allows you to enter a text string and all signature names containing the string will be displayed.

## IPS processing in an HA cluster

IPS processing in an HA cluster is no different than with a single FortiGate unit, from the point of view of the network user. The difference appears when a secondary unit takes over from the primary, and what happens depends on the HA mode.

### Active-passive

In an active-passive HA cluster, the primary unit processes all traffic just as it would in a stand-alone configuration. Should the primary unit fail, a secondary unit will assume the role of the primary unit and begin to process network traffic. By default, the state of active communication sessions are not shared with secondary units and will not survive the fail-over condition. Once the sessions are reestablished however, traffic processing will continue as normal.

If your network requires that active sessions are taken over by the new primary unit, select **Enable Session Pick-up** in your HA configuration. Because session information must be sent to all subordinate units on a regular basis, session pick-up is a resource-intensive feature and is not enabled by default.

### Active-active

The fail-over process in an active-active cluster is similar to an active-passive cluster. When the primary unit fails, a secondary unit takes over and traffic processing continues. The load-balancing schedule used to distribute sessions to the cluster members is used by the new primary unit to redistribute sessions among the remaining subordinate units. If session pick-up is not enabled, the sessions active on the failed primary are lost, and the sessions redistributed among the secondary units may also be lost. If session pick-up is enabled, all sessions are handled according to their last-known state.

## Configure IPS options

The following IPS configuration options are available:

- [Malicious URL database for drive-by exploits detection](#)
- [Customizable replacement message when IPS blocks traffic](#)
- [Hardware Acceleration](#)
- [Extended IPS Database](#)
- [Configuring the IPS engine-count](#)
- [Configuring fail-open](#)
- [Configuring the session count accuracy](#)
- [Configuring IPS intelligence](#)
- [Configuring the IPS buffer size](#)
- [Configuring protocol decoders](#)
- [Configuring security processing modules](#)
- [IPS signature rate count threshold](#)

### Malicious URL database for drive-by exploits detection

This feature uses a local malicious URL database on the FortiGate to assist in drive-by exploits detection. The database contains all malicious URLs active in the last one month, and all drive-by exploit URLs active in the last three months. The number of URLs controlled are in the one million range.

## CLI Syntax

```
config ips sensor
 edit <profile>
 set block-malicious-url [enable | disable]
 next
end
```

## Customizable IPS replacement messages for explicit proxy traffic

If you have enabled IPS in an explicit web proxy policy, you can edit a replacement message that will appear if an IPS sensor blocks internet access. Go to **System > Replacement Messages**, select **Extended View** and find **IPS Sensor Block Page** under the **Security** heading.

## Hardware Acceleration for flow-based security profiles (NTurbo and IPSA)

Some FortiGate models support a feature call NTurbo that can offload flow-based firewall sessions to NP4 or NP6 network processors. Some FortiGate models also support offloading enhanced pattern matching for flow-based security profiles to CP8 or CP9 content processors. You can use the following command to configure NTurbo and IPSA:

```
config ips global
 set np-accel-mode {none | basic}
 set cp-accel-mode {none | basic | advanced}
end
```

If the `np-accel-mode` option is available, your FortiGate supports NTurbo: `none` disables NTurbo and `basic` (the default) enables NTurbo. If the `cp-accel-mode` option is available your FortiGate supports IPSA: `none` disables IPSA, `basic` enables basic IPSA and `advanced` enables enhanced IPSA which can offload more types of pattern matching than basic IPSA. `advanced` is only available on FortiGate models with two or more CP8 processors or one or more CP9 processors.

See the **Hardware Acceleration** handbook chapter for more information about NTurbo and IPSA.

## Extended IPS Database

Some models have access to an extended IPS Database. The extended database may affect the performance of the FortiGate unit so depending on the model of the FortiGate unit the extended database package may not be enabled by default. For example, the D-series Desktop model have this option disabled by default.

This feature can only be enabled through the CLI.

```
config ips global
 set database extended
end
```

## Configuring the IPS engine-count

FortiGate units with multiple processors can run more than one IPS engine concurrently. The `engine-count` CLI command allows you to specify how many IPS engines are used at the same time:

```
config ips global
 set engine-count <int>
end
```

The recommended and default setting is 0, which allows the FortiGate unit to determine the optimum number of IPS engines.

## Configuring fail-open

IPS is likely more important to your network than uninterrupted flow of network traffic, so the fail-open behaviour of the IPS engine is disabled by default. If you would like to enable the fail-open option, use the following syntax. When enabled, if the IPS engine fails for any reason, it will fail open. This applies for inspection of all the protocols inspected by FortiOS IPS protocol decoders, including but not limited to HTTP, HTTPS, FTP, SMTP, POP3, IMAP, etc. This means that traffic continues to flow without IPS scanning. To enable:

```
config ips global
 set fail-open {enable | disable}
end
```

The default setting is `disable`.

## Configuring the session count accuracy

The IPS engine can keep track of the number of open session in two ways. An accurate count uses more resources than a less accurate heuristic count.

```
config ips global
 set session-limit-mode {accurate | heuristic}
end
```

The default is `heuristic`.

## Configuring IPS intelligence

Starting with FortiOS 5.2, `intelligent-mode` is a new adaptive detection method. This command is enabled the default and it means that the IPS engine will perform adaptive scanning so that, for some traffic, the FortiGate can quickly finish scanning and offload the traffic to NPU or kernel. It is a balanced method which could cover all known exploits. When disabled, the IPS engine scans every single byte.

```
config ips global
 set intelligent-mode {enable|disable}
end
```

## Configuring the IPS buffer size

Set the size of the IPS buffer.

```
config ips global
 set socket-size <int>
end
```

The acceptable range is from 1 to 64 megabytes. The default size varies by model. In short, `socket-size` determines how much data the kernel passes to the IPS engine each time the engine samples packets.

## Configuring protocol decoders

The FortiGate Intrusion Prevention system uses protocol decoders to identify the abnormal traffic patterns that do not meet the protocol requirements and standards. For example, the HTTP decoder monitors traffic to identify any HTTP packets that do not meet the HTTP protocol standards.

To change the ports a decoder examines, you must use the CLI. In this example, the ports examined by the DNS decoder are changed from the default 53 to 100, 200, and 300.

```
config ips decoder dns_decoder
```

```
set port_list "100,200,300"
end
```

You cannot assign specific ports to decoders that are set to **auto** by default. These decoders can detect their traffic on any port. Specifying individual ports is not necessary.

## Configuring security processing modules

FortiGate Security Processing Modules, such as the CE4, XE2, and FE8, can increase overall system performance by accelerating some security and networking processing on the interfaces they provide. They also allow the FortiGate unit to offload the processing to the security module, thereby freeing up its own processor for other tasks. The security module performs its own IPS and firewall processing, but you can configure it to favor IPS in hostile high-traffic environments.

If you have a security processing module, use the following CLI commands to configure it to devote more resources to IPS than firewall. This example shows the CLI commands required to configure a security module in slot 1 for increased IPS performance.

```
config system amc-slot
edit sw1
set optimization-mode fw-ips
set ips-weight balanced
set ips-p2p disable
set ips-fail-open enable
set fp-disable none
set ipsec-inb-optimization enable
set syn-proxy-client-timer 3
set syn-proxy-server-timer 3
end
```

In addition to offloading IPS processing, security processing modules provide a hardware accelerated SYN proxy to defend against SYN flood denial of service attacks. When using a security module, configure your DoS anomaly check for `tcp_syn_flood` with the **Proxy** action. The **Proxy** action activates the hardware accelerated SYN proxy.

## IPS signature rate count threshold

The IPS signature threshold can allow configuring a signature so that it will not be triggered until a rate count threshold is met. This provides a more controlled recording of attack activity. For example, if multiple login attempts produce a failed result over a short period of time then an alert would be sent and perhaps traffic blocked. This would be a more rational response than sending an alert every time a login failed.

The syntax for this configuration is as follows:

```
config ips sensor
edit default
config entries
edit <Filter ID number>
set rule <*id>
set rate-count <integer between 1 - 65535>
set rate-duration <integer between 1 - 65535>
```

The value of the rate-duration is an integer for the time in seconds.

```
set rate-mode <continuous | periodical>
```

The rate-mode refers to how the count threshold is met.

If the setting is “continuous”, and the action is set to block, as soon as the `rate-count` is reached the action is engaged. For example, if the count is 10, as soon as the signature is triggered 10 times the traffic would be blocked.

If the setting is “periodical”, the FortiGate allows up to the value of the rate-count incidents where the signature is triggered during the rate-duration. For example, if the rate count is 100 and the duration is 60, the signature would need to be triggered 100 times in 60 seconds for the action to be engaged.

```
set rate-track <dest-ip | dhcp-client-mac | dns-domain | none | src-ip>
```

This setting allows the tracking of one of the protocol fields within the packet.

## Enabling IPS packet logging

Packet logging saves the network packets containing the traffic matching an IPS signature to the attack log. The FortiGate unit will save the logged packets to wherever the logs are configured to be stored, whether memory, internal hard drive, a FortiAnalyzer unit, or the FortiGuard Analysis and Management Service.

You can enable packet logging in the filters. Use caution in enabling packet logging in a filter. Filters configured with few restrictions can contain thousands of signatures, potentially resulting in a flood of saved packets. This would take up a great deal of space, require time to sort through, and consume considerable system resources to process. Packet logging is designed as a focused diagnostic tool and is best used with a narrow scope.

Although logging to multiple FortiAnalyzer units is supported, packet logs are not sent to the secondary and tertiary FortiAnalyzer units. Only the primary unit receives packet logs.

---

### To enable packet logging for a filter

1. Create a filter in an IPS sensor.
2. After creating the filter, right-click the filter, and select **Enable** in the **Packet Logging** column of the filter table.
3. Select the IPS sensor in the security policy that allows the network traffic the FortiGate unit will examine for the signature.

For information on viewing and saving logged packets, see [Configuring packet logging options](#) below.

## IPS logging changes

IPS operations severely affected by disk logging are moved out of the quick scanning path, including logging, SNMP trap generation, quarantine, etc.

Scanning processes are dedicated to nothing but scanning, which results in more evenly distributed CPU usage. Slow (IPS) operations are taken care of in a dedicated process, which usually stays idle.

Setting `packet-log-history` to a value larger than 1 can affect the performance of the FortiGate unit because network traffic must be buffered. The performance penalty depends on the model, the setting, and the traffic load.

---

## Other IPS examples

### Configuring basic Intrusion Prevention

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable IPS on a FortiGate unit located in a satellite office. The satellite office contains only Windows clients.

#### Creating an IPS sensor

Most IPS settings are configured in an IPS sensor. IPS sensors are selected in firewall policies. This way, you can create multiple IPS sensors, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one IPS sensor.

#### To create an IPS sensor— GUI

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the **Create New** icon in the top of the Edit IPS Sensor window.
3. In the **Name** field, enter `basic_ips`.
4. In the **Comments** field, enter `IPS for Windows clients`.
5. Select **OK**.
6. Select the **Create New** drop-down to add a new component to the sensor and for the **Sensor Type** choose **Filter Based**.
7. In the Filter Options choose the following:
  - a. For **Severity**: select all of the options
  - b. For **Target**: select **Client** only.
  - c. For **OS**: select **Windows** only.
8. For the **Action** leave as the default.
9. Select **OK** to save the filter.
10. Select **OK** to save the IPS sensor.

#### To create an IPS sensor — CLI

```
config ips sensor
 edit basic_ips
 set comment "IPS for Windows clients"
 config entries
 edit 1
 set location client
 set os windows
 end
 end
 end
end
```

## Selecting the IPS sensor in a security policy

An IPS sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an IPS sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

### To select the IPS sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Enable the **IPS** option under **Security Profiles**.
5. Select the preferred IPS sensor from the dropdown menu.
6. Select **OK** to save the security policy.

### To select the IPS sensor in a security policy — CLI

```
config firewall policy
 edit 1
 set utm-status enable
 set ips-sensor basic_ips
 end
```

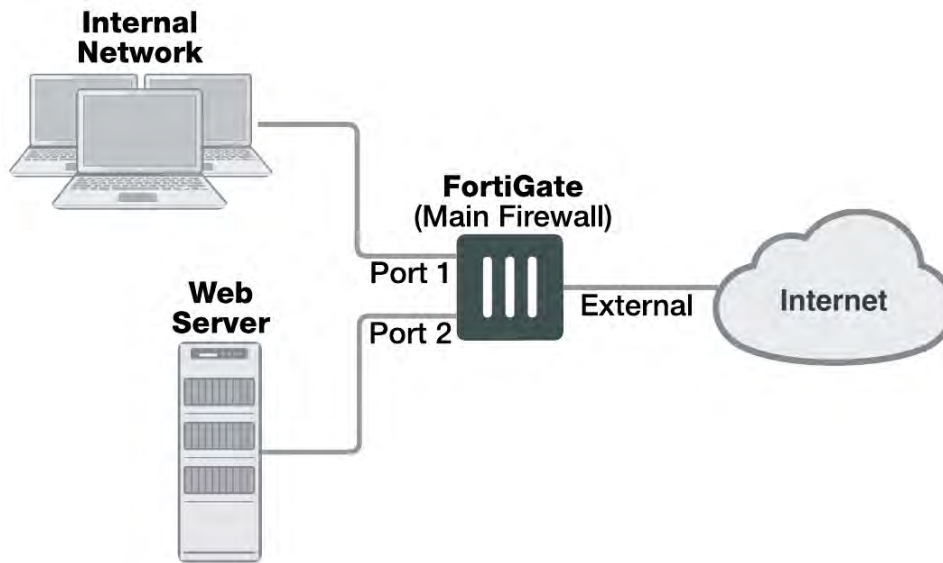

The IPS sensor in this example is `basic_ips`. All traffic handled by the security policy you modified will be scanned for attacks against Windows clients. A small office may have only one security policy configured. If you have multiple policies, consider enabling IPS scanning for all of them.

## Using IPS to protect your web server

Many companies have web servers and they must be protected from attack. Since web servers must be accessible, protection is not as simple as blocking access. IPS is one tool your FortiGate unit has to allow you to protect your network.

In this example, we will configure IPS to protect a web server. As shown below, a FortiGate unit protects a web server and an internal network. The internal network will have its own policies and configuration but we will concentrate on the web server in this example.

### A simple network configuration

The FortiGate unit is configured with:

- a virtual IP to give the web server a unique address accessible from the Internet.
- a security policy to allow access to the web server from the Internet using the virtual IP.

To protect the web server using intrusion prevention, you need to create an IPS sensor, populate it with filters, then enable IPS scanning in the security policy.

#### To create an IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **Create New**.
3. Enter `web_server` as the name of the new IPS sensor.
4. Select **OK**.

The new IPS sensor is created but it has no filters, and therefore no signatures are included.

The web server operating system is Linux, so you need to create a filter for all Linux server signatures.

#### To create the Linux server filter

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the `web_server` IPS sensor and select the **Edit** icon.
3. In the **Pattern Based Signatures and Filters** section, select **Create New**.
4. For **Sensor Type**, select **Filter Based**.
5. For **Filter Options**.
6. In the Filter Options choose the following:
  - a. For **Severity**: select all of the options
  - b. For **Target**: select **server** only.
  - c. For **OS**: select **Linux** only.
7. Select **OK**.

The filter is saved and the IPS sensor page reappears. In the filter list, find the **Linux Server** filter and look at the value in the **Count** column. This shows how many signatures match the current filter settings. You can select the **View Rules** icon to see a listing of the included signatures.

### To edit the security policy

1. Go to **Policy & Objects > IPv4 Policy** select security policy that allows access to the web server, and select the **Edit** icon.
2. Enable IPS option and choose the `web_server` IPS sensor from the list.
3. Select **OK**.

Since IPS is enabled and the `web_server` IPS sensor is specified in the security policy controlling the web server traffic, the IPS sensor examines the web server traffic for matches to the signatures it contains.

### Create and test a packet logging IPS sensor

In this example, you create a new IPS sensor and include a filter that detects the EICAR test file and saves a packet log when it is found. This is an ideal first experience with packet logging because the EICAR test file can cause no harm, and it is freely available for testing purposes.

#### Create an IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **Create New**.
3. Name the new IPS sensor `EICAR_test`.
4. Select **OK**.

#### Create an entry

1. Select the **Create New**.
2. For **Sensor Type** choose **Specify Signatures**.
3. Rather than search through the signature list, use the name filter by selecting the search icon over the header of the **Signature** column.
4. Enter `EICAR` in the Search field.
5. Highlight the `Eicar.Virus.Test.File` signature by clicking on it.
6. Select **Block** as the **Action** for the `EICAR_test` sensor in the **IPS Signatures** table.
7. Enable **Packet Logging**.
8. Select **OK** to save the IPS sensor.

#### Add the IPS sensor to the security policy allowing Internet access

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows you to access the Internet.
3. Select the **Edit** icon.
4. Go to **Security Profiles** and enable **IPS** and choose `EICAR_test` from the available IPS sensors..
5. Enable **Log Allowed Traffic** and select **All Sessions**.
6. Select **OK**.

With the IPS sensor configured and selected in the security policy, the FortiGate unit blocks any attempt to download the EICAR test file.

### Test the IPS sensor

1. Using your web browser, go to [http://www.eicar.org/anti\\_virus\\_test\\_file.htm](http://www.eicar.org/anti_virus_test_file.htm).
2. Scroll to the bottom of the page and select **ecar.com** from the row labeled as using the standard HTTP protocol.
3. The browser attempts to download the requested file and,
  - If the file is successfully downloaded, the custom signature configuration failed at some point. Check the custom signature, the IPS sensor, and the firewall profile.
  - If the download is blocked with a high security alert message explaining that you're not permitted to download the file, the EICAR test file was blocked by the FortiGate unit antivirus scanner before the IPS sensor could examine it. Disable antivirus scanning and try to download the EICAR test file again.
  - If no file is downloaded and the browser eventually times out, the custom signature successfully detected the EICAR test file and blocked the download.

### Viewing the packet log

1. Go to **Log & Report > Forward Traffic**.
2. Locate the log entry that recorded the blocking of the EICAR test file block. The Message field data will be `tools: EICAR.AV.Test.File.Download`.
3. Select the **View Packet Log** icon in the **Packet Log** column.
4. The packet log viewer is displayed.

## Configuring a Fortinet Security Processing module

The Example Corporation has a web site that is the target of SYN floods. While they investigate the source of the attacks, it's very important that the web site remain accessible. To enhance the ability of the company's FortiGate-100D to deal with SYN floods, the administrator will install an ASM-CE4 Fortinet Security Processing module and have all external access to the web server come through it.

The security processing modules not only accelerate and offload network traffic from the FortiGate unit's processor, but they also accelerate and offload security and content scanning. The ability of the security module to accelerate IPS scanning and DoS protection greatly enhances the defense capabilities of the FortiGate-100D.

### Assumptions

As shown in other examples and network diagrams throughout this document, the Example Corporation has a pair of FortiGate-100D units in an HA cluster. To simplify this example, the cluster is replaced with a single FortiGate-100D.

An ASM-CE4 is installed in the FortiGate-100D.

The network is configured as shown below.

### Network configuration

The Example Corporation network needs minimal changes to incorporate the ASM-CE4. Interface amc-sw1/1 of the ASM-CE4 is connected to the Internet and interface amc-sw1/1 is connected to the web server.

Since the main office network is connected to port2 and the Internet is connected to port1, a switch is installed to allow both port1 and amc-sw1/1 to be connected to the Internet.

## The FortiGate-100D network configuration

The switch used to connect port1 and amc-sw1/1 to the Internet must be able to handle any SYN flood, all of the legitimate traffic to the web site, and all of the traffic to and from the Example Corporation internal network. If the switch can not handle the bandwidth, or if the connection to the service provider can not provide the required bandwidth, traffic will be lost.

### Security module configuration

The Fortinet security modules come configured to give equal priority to content inspection and firewall processing. The Example Corporation is using a ASM-CE4 module to defend its web server against SYN flood attacks so firewall processing is a secondary consideration.

Use these CLI commands to configure the security module in ASM slot 1 to devote more resources to content processing, including DoS and IPS, than to firewall processing.

```

config system amc-slot
 edit sw1
 set optimization-mode fw-ips
 set ips-weight balanced
 set ips-p2p disable
 set ips-fail-open enable
 set fp-disable none
 set ipsec-inb-optimization enable
 set syn-proxy-client-timer 3
 set syn-proxy-server-timer 3
 end
end

```

These settings do not disable firewall processing. Rather, when the security module nears its processing capacity, it will chose to service content inspection over firewall processing.

## Anti-Spam filter

This section describes how to configure FortiGate email filtering for IMAP, POP3, and SMTP email. Email filtering includes both spam filtering and filtering for any words or files you want to disallow in email messages. If your FortiGate unit supports SSL content scanning and inspection, you can also configure spam filtering for IMAPS, POP3S, and SMTPS email traffic.

The Anti-Spam security profile is only available when operating the FortiGate in proxy-based inspection.

The following topics are included in this section:

## Anti-Spam concepts

You can configure the FortiGate unit to manage unsolicited commercial email by detecting and identifying spam messages from known or suspected spam servers.

The FortiGuard Anti-Spam service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools, to detect and block a wide range of spam messages. Using FortiGuard Anti-Spam profile settings, you can opt to filter with IP address checking, URL checking, email checksum checking, detection of phishing URLs in email, and spam submission. Updates to the IP reputation and spam signature databases are provided continuously via the global FortiGuard Distribution Network.

At the [FortiGuard Anti-Spam](#) service page on the [FortiGuard Labs](#) website, you can find out whether an IP address is blacklisted in the FortiGuard Anti-Spam IP reputation database, or whether a URL or email address is in the signature database.

## Anti-Spam techniques

The FortiGate unit has a number of techniques available to help detect spam. Some use the FortiGuard Anti-Spam service and require a subscription. The remainder use your DNS servers or use lists that you must maintain.

### Black white list

These are the types of black white lists available. They include:

- **IP/Netmask**

The FortiGate unit compares the IP address of the client delivering the email to the addresses in the IP address black / white list specified in the email filter profile. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry against all delivered email.

The default setting of the `smtp-spamhdrip` CLI command is `disable`. If enabled, the FortiGate unit will check all the IP addresses in the header of SMTP email against the specified IP address black / white list.

- **Email Wildcard**

The FortiGate unit compares the sender email address, as shown in the message header and envelope MAIL FROM, to the pattern in the patterned field. The wildcard symbol is used in the place of characters in the address that may vary from the pattern. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry.

- **Email Regular Expression**

The FortiGate unit compares the sender email address, as shown in the message envelope MAIL FROM, to the

pattern in the patterned field. The regular expression that can be used is much more sophisticated than a simple wildcard variable. If a match is found, the FortiGate unit will take the action configured for the matching black/white list entry.

### Pattern

The pattern field is for entering the identifying information that will enable the filter to correctly identify the email messages.

- If the type is IP/Netmask the filter will be an IP address with a subnet mask.
- If the type is Email Wildcard the filter will be an email address with a wildcard symbol in place of the variable characters. For example \*.example.com or fred@\*.com.
- If the type is Email Regular Expression, regular expression can be used to create a more granular filter for email addresses. For example, `^[_a-z0-9-]+(\.[_a-z0-9-]+)*@(example|xample|examp).(com|org|net)` could be used filter based on a number of combinations of email domain names.

### Action

- **Tag**  
If this is the selected action, the email will be allowed through but it will be tagged with an indicator that clearly marks the email as spam.
- **Pass**  
If this is the selected action, the email will be allowed to go through to its destination on the assumption that the message is not spam.
- **Discard**  
If this is the selected action, the email will be dropped at the before reaching its destination.

### Status

Indicates whether this particular list is enabled or disabled.

### Banned word check

When you enable banned word checking, your FortiGate unit will examine the email message for words appearing in the banned word list specified in the Anti-Spam profile. If the total score of the banned word discovered in the email message exceeds the threshold value set in the Anti-Spam profile, your FortiGate unit will treat the message as spam.

When determining the banned word score total for an email message, each banned word score is added once no matter how many times the word appears in the message. Use the command `config spamfilter bword` to add an email banned word list. Use the command `config spamfilter profile` to add a banned word list to an Anti-Spam profile.

### How content is evaluated

Every time the banned word filter detects a pattern in an email message, it adds the pattern score to the sum of scores for the message. You set this score when you create a new pattern to block content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the total score equals or exceeds the threshold, the email message is considered as spam and treated according to the spam action configured in the email filter profile. The score for each pattern is counted only once, even if that pattern appears many times in the email message. The default score for banned word patterns is 10 and the default threshold is 10. This means that by default, an email message is blocked by a single match.

A pattern can be part of a word, a whole word, or a phrase. Multiple words entered as a pattern are treated as a phrase. The phrase must appear as entered to match. You can also use wildcards or regular expressions to have a pattern match multiple words or phrases.

For example, the FortiGate unit scans an email message that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the email message.”

| Banned word pattern | Pattern type | Assigned score | Score added to the sum for the entire page | Comment                                                                                                                                              |
|---------------------|--------------|----------------|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| word                | Wildcard     | 20             | 20                                         | The pattern appears twice but multiple occurrences are only counted once.                                                                            |
| word phrase         | Wildcard     | 20             | 0                                          | Although each word in the phrase appears in the message, the words do not appear together as they do in the pattern. There are no matches.           |
| word*phrase         | Wildcard     | 20             | 20                                         | The wildcard represents any number of any character. A match occurs as long as “word” appears before “phrase” regardless of what is in between them. |
| mail*age            | Wildcard     | 20             | 20                                         | Since the wildcard character can represent any characters, this pattern is a match because “email message” appears in the message.                   |

In this example, the message is treated as spam if the banned word threshold is set to 60 or less.

### Adding words to a banned word list

When you enter a word, set the `Pattern-type` to wildcards or regular expressions.

**Wildcard** uses an asterisk (“\*”) to match any number of any character. For example, `re*` will match all words starting with “re”.

**Regular expression** uses Perl regular expression syntax. See <http://perldoc.perl.org/perlretut.html> for detailed information about using Perl regular expressions.

### DNS-based Blackhole List (DNSBL)

A DNSBL is a list of IP addresses, usually maintained by a third party, which are identified as being associated with spamming.

### FortiGuard-Antispam Service.

#### FortiGuard IP address check

The FortiGate unit queries the FortiGuard Anti-Spam Service to determine if the IP address of the client delivering the email is blacklisted. A match will cause the FortiGate unit to treat delivered messages as spam.

The default setting of the `smtp-spamhdrop` CLI command is `disable`. When you enable FortiGuard IP address checking, your FortiGate unit will submit the IP address of the client to the FortiGuard service for

checking. If the IP address exists in the FortiGuard IP address black list, your FortiGate unit will treat the message as spam.

### **FortiGuard URL check**

When you enable FortiGuard URL checking, your FortiGate unit will submit all URLs appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL black list, your FortiGate unit will treat the message as spam.

### **FortiGuard email checksum check**

When you enable FortiGuard email checksum checking, your FortiGate unit will submit a checksum of each email message to the FortiGuard service for checking. If a checksum exists in the FortiGuard checksum black list, your FortiGate unit will treat the message as spam.

### **Detect phishing URLs in email**

When you enable FortiGuard phishing URL detection, your FortiGate unit will submit all URL hyperlinks appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL phishing list, your FortiGate unit will remove the hyperlink from the message. The URL will remain in place, but it will no longer be a selectable hyperlink.

### **FortiGuard spam submission**

Spam submission is a way you can inform the FortiGuard Anti-Spam service of non-spam messages incorrectly marked as spam. When you enable this setting, the FortiGate unit adds a link to the end of every message marked as spam. You then select this link to inform the FortiGuard Anti-Spam service when a message is incorrectly marked.

### **Trusted IP Addresses**

A list of IP addresses that are trusted by the FortiGate is created. Any email traffic coming in from these IP address will be exempted to perform IP based check, such as DNSBL/RBL, FortiShield SPAM IP or locally defined IP black list check.

If the FortiGate unit sits behind a company's Mail Transfer Units, it may be unnecessary to check email IP addresses because they are internal and trusted. The only IP addresses that need to be checked are those from outside of the company. In some cases, external IP addresses may be added to the list if it is known that they are not sources of spam.

### **MIME header**

This feature filters by the MIME header. MIME header settings are configured in a separate part of the command tree but MIME header filtering is enabled within each profile.

### **HELO DNS lookup**

Whenever a client opens an SMTP session with a server, the client sends a HELO command with the client domain name. The FortiGate unit takes the domain name specified by the client in the HELO and does a DNS lookup to determine if the domain exists. If the lookup fails, the FortiGate unit determines that any messages delivered during the SMTP session are spam.

The HELO DNS lookup is available only for SMTP traffic.

## Return email DNS check

The FortiGate unit performs a DNS lookup on the If no such record exists, the message is treated as spam.

When you enable return email DNS checking, your FortiGate unit will take the domain in the reply-to email address and reply-to domain and check the DNS servers to see if there is an A or MX record for the domain. If the domain does not exist, your FortiGate unit will treat the message as spam.

## Configuring Anti-Spam

FortiGuard email filtering techniques us FortiGuard services to detect the presence of spam among your email. A FortiGuard subscription is required to use the FortiGuard email filters. To enable email filtering an email filter needs to be created and then the filter needs to be associated with a security policy.

The Anti-Spam security profile is only available when operating the FortiGate in proxy-based inspection.

The filter can be created as follows:

- Go to **Security Profiles > Anti-Spam**.
  - Select the **Create New** icon (a plus symbol in a circle in the upper right hand corner).
  - Select the **List** icon (a page symbol in the upper right hand corner) and in the new window select **Create New**.

An existing filter can be edited as follows:

- Go to **Security Profiles > Anti-Spam**.
  - Select the filter that you wish to edit from the dropdown menu in the upper right corner.
  - Select the List icon (a page symbol in the upper right hand corner) and select the filter that you wish to edit from the list.

Once you are in the proper **Edit Anti-Spam Profile** window, you can enter a name in the Name field if it's a new filter.

The Comments field is for a description or other information that will assist in understanding the function or purpose of the this particular filter.

Before any of the other features or options of the filter appear the checkbox next to Enable Spam Detection and Filtering must be checked.

## Spam detection by protocol

This matrix includes three rows that represent the email protocols IMAP, POP3 and SMTP.

There are also columns for:

### Spam Action

For the client protocols, IMAP and POP3 the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

For the transfer protocol, SMTP, the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Discard** - The action will drop the email before it reaches its destination.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

### Tag Location

- **Subject** - The contents of the Tag Format will be inserted into the subject line. The subject line is the most commonly used.
- **MIME** - The contents of the Tag Format will be inserted in with the MIME header header.

### Tag Format

The contents of this field will be entered into the tag location specified. The most common tag is something along the lines of [Spam] or \*\*SPAM\*\*

## FortiGuard Spam Filtering

The options in the section are ones that require a FortiGuard subscription.

The options available in this section, to be selected by checkbox are:

- IP Address Check
- URL Check
- Detect Phishing URLs in Email
- Email Checksum Check
- Spam Submission

## Local Spam Filtering

The options in the section are ones can be managed on the local device without the need for a FortiGuard subscription.

The options available in this section, to be selected by checkbox are:

- HELO DNS Lookup
- Return Email DNS Check
- Black White List - checking this option will produce a table that can be edited to create a number of black / white lists that can be separately configured and enabled.

Another local spam filter profile option that can only be configured in the CLI is the `bannedword.check`. To configure this, enter the following commands in the CLI:

```
config spamfilter profile
 edit <filter_name>
 set options bannedword
 set spam-bword-table 1
 next
end
```

See the section on [banned word checking](#) for more information on how content is evaluated.

## Order of spam filtering

The FortiGate unit checks for spam using various filtering techniques. The order in which the FortiGate unit uses these filters depends on the mail protocol used.

Filters requiring a query to a server and a reply (FortiGuard Anti-Spam service and DNSBL/ORDBL) are run simultaneously. To avoid delays, queries are sent while other filters are running. The first reply to trigger a spam action takes effect as soon as the reply is received.

Each spam filter passes the email to the next if no matches or problems are found. If the action in the filter is **Mark as Spam**, the FortiGate unit tags the email as spam according to the settings in the email filter profile.

For SMTP and SMTPS, if the action is **Discard**, the email message is discarded or dropped.

If the action in the filter is **Mark as Clear**, the email is exempt from any remaining filters. If the action in the filter is **Mark as Reject**, the email session is dropped.

## Order of SMTP and SMTPS spam filtering

The FortiGate unit scans SMTP and SMTPS email for spam in a specific order, depending on whether or not the local override feature has been enabled. By default, local override is disabled on the FortiGate. Enabling local override will give priority to local spam filters.

You can enable local override with the CLI command `set local-override {enable | disable}` when configuring a spamfilter profile. Enable this command to override SMTP or SMTPS remote check, which includes IP RBL check, IP FortiGuard AntiSpam check and HELO DNS check, with the locally defined black/white antispam list.

SMTPS spam filtering is available on FortiGate units that support SSL content scanning and inspection.

## Enabling local override of Anti-Spam filter

### CLI Syntax

```
config spamfilter profile
 edit <filter_name>
 set spam-filtering enable
 set options spambwl spamfsip spamfsurl spamhelodns spamfsphish
 config smtp
 set local-override enable
 end
 set spam-bwl-table 1
 next
end
```

## Order of SMTP and SMTPS spam filtering with local-override disabled

1. HELO DNS Lookup, Last Hop IP check against ORDBL
2. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address check, Phishing URLs detection
3. Last Hop IP check local black/white list (BWL)
4. Envelope Address check local BWL
5. Headers IPs local BWL

6. Headers email address local BWL, MIME header checks based on local list of patterns (mheader)
7. Banned words (subject first, then body) based on local BWL (bword)

### Order of SMTP and SMTPS spam filtering with local-override enabled

1. Last Hop IP check local black/white list (BWL)
2. Envelope Address check local BWL
3. Headers IPs local BWL, MIME header checks based on local list of patterns (mheader)
4. Headers email address local BWL
5. Banned words (subject first, then body) based on local list of patterns (bword)
6. HELO DNS Lookup, Last Hop IP check against ORDBL
7. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address checks, Phishing URLs detection

### Order of IMAP, POP3, IMAPS and POP3S spam filtering

The FortiGate unit scans IMAP, POP3, IMAPS and POP3S email for spam in the order given below. IMAPS and POP3S spam filtering is available on FortiGate units that support SSL content scanning and inspection.

1. MIME headers check, E-mail address BWL check
2. Banned word check on email subject
3. IP BWL check
4. Banned word check on email body
5. Return email DNS check, FortiGuard Antispam email checksum check, FortiGuard Antispam URL check, DNSBL & ORDBL check.

## Spam actions

When spam is detected, the FortiGate unit will deal with it according to the **Spam Action** setting in the anti-spam profile. Note that POP3S, IMAPS and SMTPS spam filtering is available only on FortiGate units that support SSL content scanning and inspection. POP3, IMAP, POP3S and IMAPS mail can only be tagged. SMTP and SMTPS mail can be set to **Discard** or **Tagged**:

### Discard

When the spam action is set to **Discard**, messages detected as spam are deleted. No notification is sent to the sender or recipient.

### Pass

When the spam action is set to **Pass**, the spam filter is disabled for the related protocol.

### Tag

When the spam action is set to **Tag**, messages detected as spam are labeled and delivered normally. The text used for the label is set in the **Tag Format** field and the label is placed in the subject or the message header, as set with the **Tag Location** option.

## Anti-Spam examples

### Configuring simple Anti-Spam protection

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable Anti-Spam protection on a FortiGate unit located in a satellite office.

#### Creating an email filter profile

Most Anti-Spam settings are configured in an Anti-Spam profile. Anti-Spam profiles are selected in firewall policies. This way, you can create multiple Anti-Spam profiles, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one Anti-Spam profile.

#### To create an Anti-Spam profile — web-based manager

1. Go to **Security Profiles > Anti-Spam**.
2. Select the **Create New** icon in the Edit Anti-Spam Profile window title.
3. In the **Name** field, enter `basic_anti-spam`.
4. Select **Enable Spam Detection and Filtering**.
5. Ensure that **IMAP**, **POP3**, and **SMTP** are selected in the header row.  
These header row selections enable or disable examination of each Anti-Spam type. When disabled, the email traffic of that type is ignored by the FortiGate unit and no Anti-Spam options are available.
6. Under **FortiGuard Spam Filtering**, enable **IP Address Check**.
7. Under **FortiGuard Spam Filtering**, enable **URL Check**.
8. Under **FortiGuard Spam Filtering**, enable **E-mail Checksum Check**.
9. Select **OK** to save the email filter profile.

#### To create an Anti-Spam profile — CLI

```
config spamfilter profile
edit basic_anti-spam
 set options spamfsip spamfsurl spamfschksum
end
```

#### Selecting the Anti-Spam profile in a security policy

An Anti-Spam profile directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an Anti-Spam profile is selected in a security policy, its settings are applied to all the traffic the security policy handles.

#### To select the Anti-Spam profile in a security policy — web-based manager

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create a new or edit a policy.
3. Turn on Anti-Spam.
4. Select the `basic_anti-spam` profile from the list.
5. Select **OK** to save the security policy.

## To select the Anti-Spam profile in a security policy — CLI

```
config firewall policy
 edit 1
 set utm-status enable
 set profile-protocol-options default
 set spamfilter-profile basic_anti-spam
 end
```

IMAP, POP3, and SMTP email traffic handled by the security policy you modified will be scanned for spam. Spam messages have the text “Spam” added to their subject lines. A small office may have only one security policy configured. If you have multiple policies, consider enabling spam scanning for all of them.

## Blocking email from a user

Employees of the Example.com corporation have been receiving unwanted email messages from a former client at a company called example.net. The client’s email address is client@example.net. All ties between the company and the client have been severed, but the messages continue. The FortiGate unit can be configured to prevent these messages from being delivered.

## To enable Anti-Spam

1. Go to **Security Profiles > Anti-Spam**.
2. Select the Anti-Spam profile that is used by the firewall policies handling email traffic from the Anti-Spam profile drop down list.
3. In the row **Tag Location**, select **Subject** for all three mail protocols.
4. In the row **Tag Format**, enter `SPAM:` in all three fields.  
This means that normal spam will be tagged in the subject line.
5. Select **Enable Spam Detection and Filtering**.
6. Under **Local Spam Filtering**, enable **Black White List** and select **Create New**.
7. In the Black White List widget, select **Create New**.
8. Select **Email Address Wildcard**.
9. Enter `client@example.net` in the **Pattern** field.
  - If you wanted to prevent everyone’s email from the client’s company from getting through you could have used `*@example.net` instead.
10. Set the **Action** as **Mark as Spam**.
11. Set the **Status** to **Enable**.
12. Confirm that the SMTP protocol action is set to **Discard**.
13. Select **OK**.

Now that the email address list is created, you must enable the email filter in the Anti-Spam profile.

When this Anti-Spam profile is selected in a security policy, the FortiGate unit will reject any email message from an address ending with `@example.net` for all email traffic handled by the security policy.

## Data leak prevention

The FortiGate data leak prevention (DLP) system allows you to prevent sensitive data from leaving your network. When you define sensitive data patterns, data matching these patterns will be blocked, or logged and allowed, when passing through the FortiGate unit. You configure the DLP system by creating individual filters based on file type, file size, a regular expression, an advanced rule, or a compound rule, in a DLP sensor and assign the sensor to a security policy.

Although the primary use of the DLP feature is to stop sensitive data from leaving your network, it can also be used to prevent unwanted data from entering your network and to archive some or all of the content passing through the FortiGate unit.

This section describes how to configure the DLP settings. DLP can only be configured for FortiGate units in proxy-based inspection.

The following topics are included:

- [Data leak prevention concepts](#)
- [Enable data leak prevention](#)
- [Creating or editing a DLP sensor](#)
- [DLP archiving](#)
- [DLP examples](#)

## Data leak prevention concepts

Data leak prevention examines network traffic for data patterns you define through the use of the GUI and CLI commands. The DLP feature is broken down into a number of parts. Note, DLP is not available in flow-based inspection.

### DLP sensor

A DLP sensor is a package of filters. To use DLP, you must enable it in a security policy and select the DLP sensor to use. The traffic controlled by the security policy will be searched for the patterns defined in the filters contained in the DLP sensor. Matching traffic will be passed or blocked according to how you configured the filters.

### DLP filter

Each DLP sensor has one or more filters configured within it. Filters can examine traffic for known files using DLP fingerprints, for files of a particular type or name, for files larger than a specified size, for data matching a specified regular expression, or for traffic matching an advanced rule or compound rule.

### DLP Filter Actions

You can configure the action taken when a match is detected. The actions include:

- Allow
- Log Only
- Block
- Quarantine IP address

**Log Only** is enabled by default.

### Allow

The FortiGate takes no action, even if the patterns specified in the filter are matched.

### Log Only

The FortiGate takes no action on network traffic matching a rule with this action. The filter match is logged.

### Block

Traffic matching a filter with the block action will not be delivered. The matching message or download is replaced with the data leak prevention replacement message.

### Quarantine IP Address/ Source IP ban

Starting in FortiOS 5.2, the quarantine, as a place where traffic content was held in storage so it couldn't interact with the network or system, was removed. The term quarantine was kept to describe preventing selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

If the **quarantine-ip** action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP address will be blocked. In the GUI it is shown as a field before minutes. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

If a DLP sensor has contains a DLP filter with action set to **Allow** certain files and another DLP filter with action set to **Block** those same files, then the order of the filters within that sensor will determine which action is taken first.

---

### Configuring using the CLI

To configure the DLP sensor to add the source IP address of the sender of a protected file to the quarantine or list of banned source IP addresses edit the DLP Filter, use these CLI commands:

```
config dlp sensor
 edit <sensor name>
 config filter
 edit <id number of filter>
 set action quarantine-ip
 set expiry 5m
 end
 end
 end
```

### Preconfigured sensors

A number of preconfigured sensors are provided with your FortiGate unit. These can be edited to more closely match your needs.

Two of the preconfigured sensors with filters ready for you to enable are:

- Credit-Card - This sensor logs the traffic, both files and messages, that contain credit card numbers in the formats used by American Express, MasterCard and Visa.
- SSN-Sensor - This sensor logs the traffic, both files and messages, that contain Social Security Numbers with the exception of those that are WebEx invitation emails.

These rules affect only unencrypted traffic types. If you are using a FortiGate unit that can decrypt and examine encrypted traffic, you can enable those traffic types in these rules to extend their functionality if required.

---

Before using the rules, examine them closely to ensure you understand how they will affect the traffic on your network.

---

## DLP document fingerprinting

One of the DLP techniques to detect sensitive data is fingerprinting (also called document fingerprinting). Most DLP techniques rely on you providing a characteristic of the file you want to detect, whether it's the file type, the file name, or part of the file contents. Fingerprinting is different in that you provide the file itself. The FortiGate unit then generates a checksum fingerprint and stores it. The FortiGate unit generates a fingerprint for all files detected in network traffic, and it is compared to all of the fingerprints stored in its fingerprint database. If a match is found, the configured action is taken.

The document fingerprint feature requires a FortiGate unit with internal storage.

Any type of file can be detected by DLP fingerprinting and fingerprints can be saved for each revision of your files as they are updated.

To use fingerprinting you:

- select the documents to be fingerprinted
- add fingerprinting filters to DLP sensors
- add the sensors to firewall policies that accept the traffic to which to apply fingerprinting.

## Fingerprinting

Fingerprint scanning allows you to create a library of files for the FortiGate unit to examine. It will create checksum fingerprints so each file can be easily identified. Then, when files appear in network traffic, the FortiGate will generate a checksum fingerprint and compare it to those in the fingerprint database. A match triggers the configured action.

You must configure a document source or uploaded documents to the FortiGate unit for fingerprint scanning to work.

## Fingerprinted Documents

The FortiGate unit must have access to the documents for which it generates fingerprints.

## Configuring the document source

To configure a DLP fingerprint document source in FortiOS 5.6.0, you must use CLI commands.

```
config dlp fp-doc-source
```

```
edit <name_str>
 set name <string>
 set server-type {smb}
 set server <string>
 set period {none | daily | weekly | monthly}
 set vdom {mgmt | current}
 set scan-subdirectories {enable | disable}
 set remove-deleted {enable | disable}
 set keep-modified {enable | disable}
 set username <string>
 set password <password>
 set file-path <string>
 set file-pattern <string>
 set sensitivity <string>
 set tod-hour <integer>
 set tod-min <integer>
 set weekday {sunday | monday | tuesday | wednesday | thursday | friday | saturday}
 set date <integer>
end
```

## Configuring a DLP fingerprint sensor

To configure a DLP fingerprint sensor in FortiOS 5.6.0, you must use CLI commands.

```
config dlp sensor
 edit <sensor name>
 config filter
 edit <id number of filter>
 set proto {smtp | pop3 | imap http-get | http-post | ftp | nntp | mapi}
 set filter-by fingerprint
 set fp-sensitivity { critical | private | warning}
 set action {allow | log-only | block | ban | quarantine-ip | quarantine-
 port}
 next
 end
 next
```

Once you have set the document source and configured the DLP sensor for fingerprinting, add the DLP sensor to the applicable firewall policy. This can be done through the GUI.

## File size

This filter-type checks for files exceeding a configured size. All files larger than the specified size are subject to the configured action. The value of the field is measured in kilobytes (KB).

## DLP filtering by specific file types

File filters use file filter lists to examine network traffic for files that match either file names or file types. For example, you can create a file filter list that will find files called secret.\* and also all JPEG graphic files. You can create multiple file filter lists and use them in filters in multiple DLP sensors as required.

**Specify File Types** is a DLP option that allows you to block files based on their file name or their type.

- **File types** are a means of filtering based on examination of the file contents, regardless of the file name. If you block the file type **Archive (zip)**, all zip archives are blocked even if they are renamed with a different file extension. The FortiGate examines the file contents to determine what type of file it is and then acts accordingly.
- **File Name patterns** are a means of filtering based purely on the names of files. They may include wildcards (\*). For example, blocking \*.scr will stop all files with an .scr file extension, which is commonly used for Windows screen saver files. Files trying to pass themselves off as Windows screen saver files by adopting the file-naming convention will also be stopped.
  - Files can specify the full or partial file name, the full or partial file extension, or any combination. File pattern entries are not case sensitive. For example, adding \*.exe to the file pattern list also blocks any files ending with .exe.
  - Files are compared to the enabled file patterns from top to bottom, in list order.

If DLP detects a file inside an archive that should be blocked, the entire archive will be blocked.

---

## Watermarking

Watermarking is essentially marking files with a digital pattern to mark the file as being proprietary to a specific company. Fortinet provides a Linux-based utility that applies a digital watermark to files. The utility adds a small (approx. 100 byte) pattern to the file that is recognized by the DLP watermark filter. The pattern is invisible to the end user.

When watermarking a file it should be verified that the pattern matches up to a category found on the FortiGate firewall. For example, if you are going to watermark a file with the sensitivity level of “Secret” you should verify that “Secret” is a sensitivity level that has been assigned in the FortiGate unit.

### Watermark Sensitivity

If you are using watermarking on your files you can use this filter to check for watermarks that correspond to sensitivity categories that you have set up.

The Corporate Identifier is to make sure that you are only blocking watermarks that your company has place on the files, not watermarks with the same name by other companies.

### Software Versions

Before planning on using watermarking software it is always best to verify that the software will work with your OS. Currently, the only utility available to watermark files is a Linux-based command line tool. It is available for download from the [Fortinet Customer Service & Support](#) website, with a valid support contract and access to the site. To access the file:

1. Sign into the [Fortinet Customer Service & Support](#) website.
2. Go to <https://support.fortinet.com/Download/FirmwareImages.aspx>.
3. Navigate to the image file path for /FortiGate / v5.00 / 5.0 / WATERMARK
4. Download the file **fortinet-watermark-linux.out**.

### File types

The watermark utility does not work with every file type. The following file types are supported by the watermark tool: .txt; .pdf; .doc; .xls; .ppt; .docx; pptx; and, .xlsx.

## Syntax of the watermark utility

The tool is executed in a Linux environment by passing in files or directories of files to insert a watermark.

### USAGE:

```
watermark_linux_amd64 <options> -f <file name> -i <identifier> -l <sensitivity level>
watermark_linux_amd64 <options> -d <directory> -i <identifier> -l <sensitivity level>
```

### Options:

```
-h print help
-I inplace watermarking (don't copy file)
-o output file (or directory in directory mode)
-e encode <to non-readable>
-i add watermark identifier
-l add watermark sensitivity level
-D delete watermark identifier
-L delete watermark sensitivity level
```

## Regular expression

The FortiGate unit checks network traffic for the regular expression specified in a regular expression filter. The regular expression library used by Fortinet is a variation of a library called PCRE (Perl Compatible Regular Expressions). A number of these filters can be added to a sensor making a sort of 'dictionary' subset within the sensor.

Some other, more limited DLP implementations, use a list of words in a text file to define what words are searched for. While the format used here is slightly different than what some people are used to, the resulting effect is similar. Each regular expression filter can be thought of as a more versatile word to be searched against. In this dictionary (or sensor), the list of words is not limited to just predefined words. It can include expressions that accommodate complex variations on those words and even target phrases. Another advantage of the individual filter model of this dictionary over the list is that each word can be assigned its own action, making this implementation much more granular.

## Encrypted

This filter is a binary one. If the file going through the policy is encrypted the action is triggered.

## Examining specific services

To assist in optimizing the performance of the firewall, the option exists to select which services or protocol traffic will be checked for the targeted content. This setting gives you a tool to save the resources of the FortiGate unit by only using processing cycles on the relevant traffic. Just check the boxes associated with the service / protocol that you want to have checked for filter triggers.

## Enable data leak prevention

DLP examines your network traffic for data patterns you specify. The FortiGate unit then performs an action based on the which pattern is found and a configuration set for each filter trigger.

DLP is not available in flow-based inspection.

## General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. [Create a DLP sensor](#).  
New DLP sensors are empty. You must create one or more filters in a sensor before it can examine network traffic.
2. Add one or more filters to the DLP sensor.  
Each filter searches for a specific data pattern. When a pattern in the active DLP sensor appears in the traffic, the FortiGate unit takes the action configured in the matching filter. Because the order of filters within a sensor cannot be changed, you must configure DLP in sequence.
3. Add the DLP sensor to one or more firewall policies that control the traffic to be examined.

## Creating/editing a DLP sensor

DLP sensors are collections of filters. You must also specify an action for the filter when you create it in a sensor. Once a DLP sensor is configured, you add it to a security policy profile. Any traffic handled by that security policy will be examined according to the DLP sensor configuration.

DLP is not available in flow-based inspection.

### To create/edit a DLP sensor in the GUI

1. Go to **Security Profiles > Data Leak Prevention**.
2. Choose whether you want to edit an existing sensor or create a new one.
  - The default sensor is the one displayed by default.
  - To edit an existing sensor, select it by either using the drop down menu in the upper right hand corner of the window or by selecting the **List** icon (the furthest right of the 3 icons in the upper right of the window, resembling a page with some lines on it), and then selecting the profile you want to edit from the list.
  - To create a new sensor, select the **Create New** icon (a plus sign within a circle) or the List icon and then select the Create New link in the upper left corner of the window that appears.
3. Enter a name in the **Name** field for any new DLP sensors.
4. Optionally, you may also enter a comment. The comment appears in the DLP sensor list and can remind you of the details of the sensor.
5. At this point you can add filters to the sensor (see adding filters to a DLP sensor) or select **OK** to save the sensor. Without filters, the DLP sensor will do nothing.

## Adding filters to a DLP sensor

Once you have created a DLP sensor, you need to add filters.

1. To add filters to a DLP sensor
2. Go to **Security Profiles > Data Leak Prevention**.
3. Select the sensor you wish to edit using the drop-down menu or the sensor list window.
4. Within the Edit DLP Sensor window select **Create New**. A New Filter window should pop up.
5. Select the type of filter. You can choose either **Messages** or **Files**, depending on which of these two are chosen different options will be available.

Message filter will have these configuration options:

- [radio button] Containing: [drop-down menu including: Credit Card # or SSN]
- [radio button] Regular Expression [input field]

Examine the following services:

**Web Access**

- HTTP-POST

**Email**

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

**Others**

- [check box] NNTP

**Action** [from drop-down menu]

- Allow
- Log Only (default)
- Block
- Quarantine IP address

Files filter will allow you to choose one of these options:

- **Containing:** drop-down menu including: Credit Card # or SSN
- **File Size** > [ ]KB files greater than the number of KB entered
- Specify File Types  
File Types: ["Click to add..."drop-down menu of File extensions]  
File Name Patterns:["Click to add..."drop-down menu]
- [radio button] Regular Expression [input field]
- [radio button] Encrypted

Examine the following Services:

**Web Access**

- [check box] HTTP-POST
- [check box] HTTP-GET

**Email**

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

**Others**

- [check box] FTP
- [check box] NNTP

**Action** [from drop-down menu]

- Allow
  - Log Only (default)
  - Block
  - Quarantine IP address
6. Select **OK**.
  7. Repeat Steps 6 and 7 for each filter.
  8. Select **Apply** to confirm the settings of the sensor.

If you have configured DLP to block IP addresses and if the FortiGate unit receives sessions that have passed through a NAT device, all traffic from that NAT device — not just traffic from individual users — could be blocked. You can avoid this problem by implementing authentication.

---

To view or modify the replacement message text, go to **System > Replacement Messages**.

---

## DLP archiving

DLP is typically used to prevent sensitive information from getting out of your company network, but it can also be used to record network use. This is called DLP archiving. The DLP engine examines email, FTP, NNTP, and web traffic. Enabling archiving for rules when you add them to sensors directs the FortiGate unit to record all occurrences of these traffic types when they are detected by the sensor.

Since the archive setting is configured for each rule in a sensor, you can have a single sensor that archives only the things you want.

You can archive Email, FTP, HTTP, and session control content:

- Email content includes IMAP, POP3, and SMTP sessions. Email content can also include email messages tagged as spam by Email filtering. If your unit supports SSL content scanning and inspection, email content can also include IMAPS, POP3S, and SMTPS sessions.
- HTTP content includes HTTP sessions. If your unit supports SSL content scanning and inspection HTTP content can also include HTTPS sessions.

DLP archiving comes in two forms: **Summary** and **Full**.

Summary archiving records information about the supported traffic types. For example, when an email message is detected, the sender, recipient, message subject, and total size are recorded. When a user accesses the Web, every URL the user visits recorded. The result is a summary of all activity the sensor detected.

For more detailed records, use full archiving . When an email message is detected, the message itself, including any attachments, is archived. When a user accesses the Web, every page the user visits is archived. Far more detailed than a summary, full DLP archives require more storage space and processing.

Because both types of DLP archiving require additional resources, DLP archives are saved to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service (subscription required).

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service. DLP archiving is available for FortiAnalyzer when you add a

FortiAnalyzer unit to the Fortinet configuration. The FortiGuard Analysis server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

Two sample DLP sensors are provided with DLP archiving capabilities enabled. If you select the `Content_Summary` sensor in a security policy, it will save a summary DLP archive of all traffic the security policy handles. Similarly, the `Content_Archive` sensor will save a full DLP archive of all traffic handled the security policy you apply it to. These two sensors are configured to detect all traffic of the supported types and archive them. You can see these sensors in the GUI but the configuration is only visible through the CLI; DLP archiving is set in the CLI only.

To set the archive to Summary

```
config dlp sensor
 edit <name of sensor>
 set summary-proto smtp pop3 imap http ftp nntp msn yahoo mapi
 end
```

To set the archive to Full

```
config dlp sensor
 edit <name of sensor>
 set full-archive-proto smtp pop3 imap http ftp nntp msn yahoo mapi
 end
```

If you set the `full-archive-proto` filter to include one or more of the protocols set by the `proto` option, then the archive action is disabled.

---

## DLP examples

You can configure DLP sensors and filters when your FortiGate is operating in proxy-based inspection.

- [Blocking content with credit card numbers](#)
- [Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB](#)
- [Blocking selectively based on a fingerprint](#)

### Blocking content with credit card numbers

When the objective is to block credit card numbers one of the important things to remember is that two filters will need to be used in the sensor. One filter is to prevent sensitive files from being leaked and another is to retain any sensitive data that is not a file (for example, messages or email content).

In the default Credit-Card sensor, you will notice a few things.

- The **Action** is set to **Log Only**
- In the **Files** filter not all of the services are being examined.

If you wish to block as much content as possible with credit card numbers in it instead of just logging most the traffic that has it, the existing sensor will have to be edited.

1. Go to **Security Profiles > Data Leak Prevention**.

Some configurations will have a preconfigured Credit Card sensor where you can use the drop down menu to select **Credit-Card**. If your configuration doesn't already have one create a new sensor.

2. Use the **Create New** icon to add a new sensor.
3. *Create/edit the first filter.* Set **Type** to **Messages** and select **Containing Credit Card #**.
4. Go to **Examine the Following Services** and select all services .
5. Set **Action** to **Block**.
6. Select **OK** or **Apply**.
7. *Create/edit the second filter.* Set **Type** to **Files** and select **Containing Credit Card #**.
8. Go to **Examine the Following Services** and select all services .
9. Set **Action** to **Block**.
10. Select **OK** or **Apply**.
11. Edit the appropriate policies so that under **Security Profiles**, **DLP** is turned on and the **Credit-Card** sensor is selected.

### Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB

Multiple filters will have to be used in this case and the order that they are used is important. Because there is no mechanism to move the filters within the sensor the order that they are added to the sensor is important.

1. Go to **Security Profiles > Data Leak Prevention**.
2. Use the **Create New** icon to add a new sensor. Give it a descriptive **Name**, such as *block\_large\_emails*. Optionally, enter a descriptive comment.

Once the sensor has been created, a new filter will need to be added.

3. *Create the filter to block the emails over 15 MB.* In the filters table select **Create New**.
4. Set **Type** to **Messages** and enter 15360 in the field next to **File size over**. (1MB = 1024KB, 15 MB = 15 x 1024KB = 15360KB)
5. Go to **Examine the Following Services** and select all **Email** services .
6. Set **Action** to **Block**.
7. Select **OK**.
8. *Create the filter to log emails between 5 MB and 10 MB.* In the filters table select **Create New**.
9. Set **Type** to **Files**.
10. Enter 5120 in the field next to **File size over**. (1MB = 1024KB, 5 MB = 5 x 1024KB = 5124KB)
11. Go to **Examine the Following Services** and select all the email services .
12. Set action to **Log Only**.
13. Select **OK**.

The reason that the block filter is placed first is because the filters are applied in sequence and once the traffic triggers a filter, the action is applied and then the traffic is passed on to the next test. If the Log Only filter which checks for anything over 1MB is triggered this would include traffic over 15MB, so a 16 MB file would only be logged. In the described order, the 16 MB file will be blocked and the 3 MB file will be logged.

### Blocking selectively based on a fingerprint

The following is a fairly complex example but shows what can be done by combining various components in the correct configuration.

The company has a number of copyrighted documents that it does not want “escaping” to the Internet but it does want to be able to send those documents to the printers for turning into hardcopy.

The policies and procedures regarding this issue state that:

- Only members of the group **Senior\_Editors** can send copyrighted material to the printers.
- Every member of the company by default is included in the group **employees**.
- Even permitted transmission of copyrighted material should be recorded.
- All of the printers IP addresses are in a group called **approved\_printers**.
- There is a file share called **copyrighted** where any file that is copyrighted is required to have a copy stored.
- It doesn't happen often but for legal reasons sometimes these files can be changed, but all versions of a file in this directory need to be secured.
- All network connections to the Internet must have AntiVirus enabled using at least the default profile.
- The SSL/SSH Inspection profile used will be **default**.

It is assumed for the purposes of this example that:

- Any addresses or address groups have been created.
- User accounts and groups have been created.
- The account used by the FortiGate is fgtaccess.
- The copyrighted sensitivity level needs to be created.
- The copyrighted material is stored at \\192.168.27.50\books\copyrighted\

1. Add a new Sensitivity Level by running the following commands in the CLI:

```
config dlp fp-sensitivity
 edit copyrighted
end
```

2. Apply files to the fingerprint database by running these commands in the CLI:

```
config dlp fp-doc-source
 edit "copyrighted_material"
 set server-type smb
 set server 192.168.27.50
 set username fgtaccess
 set password *****
 set file-path books/copyrighted/
 set file-pattern *.pdf
 set sensitivity copyrighted
 set period daily
 set tod-hour 2
 set tod-min 0
 set scan-subdirectories enable
 set remove-deleted disable
 set keep-modified enable
 next
end
```

Two Sensors need to be created. One for blocking the transmission of copyrighted material and a second for allowing the passing of copyrighted material under specific circumstances.

3. Create the first DLP Sensor with the following commands in CLI:

```
config dlp sensor
 edit block_copyrighted
```

```
config filter
 edit 1
 set proto smtp pop3 imap http-get http-post ftp nntp mapi
 set filter-by fingerprint
 set fp-sensitivity copyrighted
 set action block
 next
end
next
```

#### 4. Create the second DLP Sensor

```
config dlp sensor
 edit allow_copyrighted
 config filter
 edit 2
 set proto smtp pop3 imap http-get http-post ftp nntp mapi
 set filter-by fingerprint
 set fp-sensitivity copyrighted
 set action log-only
 next
 end
 next
```

#### 5. Create a policy to allow transmission of copyrighted material.

- a. Go to **Policy & Objects > IPv4 Policy**.
- b. Select **Create New**.
- c. Use the following values in the policy:

|                            |                                              |
|----------------------------|----------------------------------------------|
| <b>Incoming Interface</b>  | LAN                                          |
| <b>Source Address</b>      | all                                          |
| <b>Outgoing Interface</b>  | wan1                                         |
| <b>Destination Address</b> | all                                          |
| <b>Schedule</b>            | always                                       |
| <b>Service</b>             | all                                          |
| <b>Action</b>              | ACCEPT                                       |
| <b>Enable NAT</b>          | enabled -- Use Destination Interface Address |
| <b>AntiVirus</b>           | <ON> default                                 |
| <b>DLP</b>                 | <ON> Copyrighted                             |
| <b>SSL/SSH Inspection</b>  | <ON> default                                 |
| <b>Enable this policy</b>  | <ON>                                         |

This policy should be placed as close to the beginning of the list of policies so the it is among the first

tested against.

6. Create a policy to block transmission of copyrighted material.  
This will in effect be the default template for all following policies in that they will have to use the DLP profile that blocks the transmission of the copyrighted material.

- a. Go to **Policy & Objects > IPv4 Policy**.

- b. Select **Create New** or Edit an existing policy.

- c. Use the following values in the Policy:

The fields should include what ever values you need to accomplish your requirements are but each policy should include the DLP sensor block\_copyrighted. Alternatively, if a different DLP configuration is required it should include a filter that blocks **copyrighted** fingerprinted file.

If you need to create a policy that is identity based make sure that there is an Authentication rule for the group **employees** that uses the DLP sensor that blocks copyrighted material.

## ICAP support

ICAP is the acronym for Internet Content Adaptation Protocol. The purpose of the feature is to offload work that would normally take place on the firewall to a separate server specifically set up for the specialized processing of the incoming traffic. This takes some of the resource strain off of the FortiGate firewall leaving it to concentrate its resources on things that only it can do.

Offloading value-added services from Web servers to ICAP servers allows those same web servers to be scaled according to raw HTTP throughput versus having to handle these extra tasks.

ICAP servers are focused on a specific function, for example:

- Ad insertion
- Virus scanning
- Content translation
- HTTP header or URL manipulation
- Language translation
- Content filtering

The following topics are included in this section:

ICAP does not appear by default in the GUI. You must enable it in **System > Feature Visibility**.

---

## The protocol

ICAP is an Application layer protocol; its specifications are set out in [RFC 3507](#). It is, in essence, a lightweight protocol for executing a "remote procedure call" on HTTP messages and is a member of the member of the TCP/IP suite of protocols.

The default TCP that is assigned to it is 1344. Its purpose is to support HTTP content adaptation by providing simple object-based content vectoring for HTTP services. ICAP is usually used to implement virus scanning and content filters in transparent HTTP proxy caches. Content adaptation refers to performing the particular value added service, or content manipulation, for an associated client request/response.

Essentially it allows an ICAP client, in this case the FortiGate firewall, to pass HTTP messages to an ICAP server like a remote procedure call for the purposes of some sort of transformation or other processing adaptation. Once the ICAP server has finished processing the content, the modified content is sent back to the client.

The messages going back and forth between the client and server are typically HTTP requests or HTTP responses. While ICAP is a request/response protocol similar in semantics and usage to HTTP/1.1 it is not HTTP nor does it run over HTTP, as such it cannot be treated as if it were HTTP. For instance, ICAP messages can not be forwarded by HTTP surrogates.

## Offloading using ICAP

If you enable ICAP in a security policy, HTTP traffic intercepted by the policy is transferred to an ICAP server in the ICAP profile added to the policy. Responses from the ICAP server are returned to the FortiGate unit which forwards them to an HTTP client or server.

You can offload HTTP responses or HTTP requests (or both) to the same or different ICAP servers.

If the FortiGate unit supports HTTPS inspection, HTTPS traffic intercepted by a policy that includes an ICAP profile is also offloaded to the ICAP server in the same way as HTTP traffic.

When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

## Configuring ICAP

You will need to configure an ICAP [server](#) and an ICAP [profile](#).

### ICAP Servers

1. Go to **Security Profiles > ICAP Servers** and click on **Create New**.
2. Enter a **Name** for the server.
3. Enter the server's **IP Address**. Depending on whether you've set the IP version to 4 or 6 will determine the format that the content of this field will be set into. In the GUI it looks like the same field with a different format but in the CLI it is actually 2 different fields named "ip-address" and ip6-address.
4. Set the **Port**; 1344 is default TCP port used for the ICAP traffic. The range can be from 1 to 65535.

### Maximum Connections

This value refers to the maximum number of concurrent connections that can be made to the ICAP server. The default setting is 100. This setting can only be configured in the CLI.

The syntax is:

```
config icap server
 edit <icap_server_name>
 set max-connections <integer>
 end
```

### Profiles

1. Go to **Security Profiles > ICAP** and click on **Create New**.
2. Enter a **Name** for the server.
3. Enable settings as required.
  - a. **Enable Request Processing** allows the ICAP server to process request messages. If enabled this setting will also require:
    - **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
    - **Path** - This is the path on the server to the processing content. For instance if the Windows share name was "Processes" and the directory within the share was "Content-Filter" the path would be "/Processes/Content-Filter/"
    - **On Failure** - There are 2 options: **Error** or **Bypass**.

- b. **Enable Response Processing** allows the ICAP server to process response messages. If enabled this setting will also require:
  - **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
  - **Path** - This is the path on the server to the processing compent. For instance if the Windows share name was "Processes" and the directory within the share was "Content-Filter" the path would be "/Processes/Content-Filter/"
  - **On Failure** - There are 2 options. You can choose by the use of radio buttons either **Error** or **Bypass**.
- c. **Enable Streaming Media Bypass** allows streaming media to ignore offloading to the ICAP server.
- 4. Select **Apply**.

## Example ICAP sequence

This example is for an ICAP server performing web URL filtering on HTTP requests

1. A user opens a web browser and sends an HTTP request to connect to a web server.
2. The FortiGate unit intercepts the HTTP request and forwards it to an ICAP server.
3. The ICAP server receives the request and determines if the request is for URL that should be blocked or allowed.
  - If the URL should be blocked the ICAP server sends a response to the FortiGate unit. The FortiGate unit returns this response to the user's web browser. This response could be a message informing the user that their request was blocked.
  - If the URL should be allowed the ICAP server sends a request to the FortiGate unit. The FortiGate unit forwards the request to the web server that the user originally attempted to connect to.
  - When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

## Example ICAP scenario

Information relavent to the following example:

- The ICAP server is designed to do proprietary content filtering specific to the organization so it will have to receive the messages and sent back appropriate responses.
  - The content filter is a required security precaution so it if the message cannot be processed it is not allowed through.
  - Resources on both the FortiGate and the ICAP server are considerable so the maximum connections setting will set at a double the default value to analyze the impact on performance.
  - The ICAP server's IP address is 172.16.100. 55.
  - The path to the processing component is "/proprietary\_code/content-filter/".
  - Streaming media is not something that the filter considers, but is allowed through the policy so processing it would be a waste of resources.
  - The ICAP profile is to be added to an existing firewall policy.
  - It is assumed that the display of the policies has already been configured to show the column "ID".
1. Enter the following to configure the ICAP server:

Go to **Security Profiles > ICAP Servers**.

Use the following values:

|                   |                            |
|-------------------|----------------------------|
| <b>Name</b>       | content-filtration-server4 |
| <b>IP Type</b>    | IPv4                       |
| <b>IP Address</b> | 172.16.100.55              |
| <b>Port</b>       | 1344                       |

Use the CLI to set the max-connections value.

```
config icap server
 edit content-filtration-server4
 set max-connections 200
 end
```

2. Enter the following to configure the ICAP profile to then apply to a security policy:

Use the following values:

|                                      |                                   |
|--------------------------------------|-----------------------------------|
| <b>Name</b>                          | Prop-Content-Filtration           |
| <b>Enable Request Processing</b>     | enable                            |
| <b>Server</b>                        | content-filtration-server4        |
| <b>Path</b>                          | /proprietary_code/content-filter/ |
| <b>On Failure</b>                    | Error                             |
| <b>Enable Response Processing</b>    | enable                            |
| <b>Server</b>                        | content-filtration-server4        |
| <b>Path</b>                          | /proprietary_code/content-filter/ |
| <b>On Failure</b>                    | Error                             |
| <b>Enable Streaming Media Bypass</b> | enable                            |

3. Apply the ICAP profile to policy:

The purposes of this particular ICAP profile is to filter the content of the traffic coming through the firewall via policy ID#17.

- a. Go to **Policy & Objects > IPv4 Policy**.
- b. Open the existing policy ID# 17 for editing.
- c. Go to the section **Security Profiles**.
- d. Select the button next to **ICAP** so that it indicates that it's status is **ON**.
- e. Select the field with the profile name and use the drop down menu to select **Prop-Content-Filtration**.
- f. Select **OK**.

## FortiClient Profiles

This section describes the FortiClient Profiles endpoint protection features and configuration.

FortiClient Profiles are used primarily to make sure connected devices are compliant with Endpoint Control and to protect against vulnerabilities. Both **Endpoint Vulnerability Scan on Client** and **System compliance** are enabled by default, while other settings are disabled by default. This allows FortiClient to work as part of a Security Fabric.

**You must first enable this feature. Go to System > Feature Visibility and enable Endpoint Control. This will reveal the Security Profiles > FortiClient Profiles menu item.**

The following topics are included in this section:

### Endpoint protection overview

Endpoint Protection enforces the use of up-to-date FortiClient Endpoint Security software on endpoints (workstation computers and mobile devices). It pushes a FortiClient profile to the FortiClient application, specifying security settings, including:

- Real-time antivirus protection - on or off
- FortiClient web category filtering based on web filters defined in a FortiGate Web Filter profile
- FortiClient Application Control (application firewall) using application sensors defined in the FortiGate Application Control profile

The FortiClient profile can also:

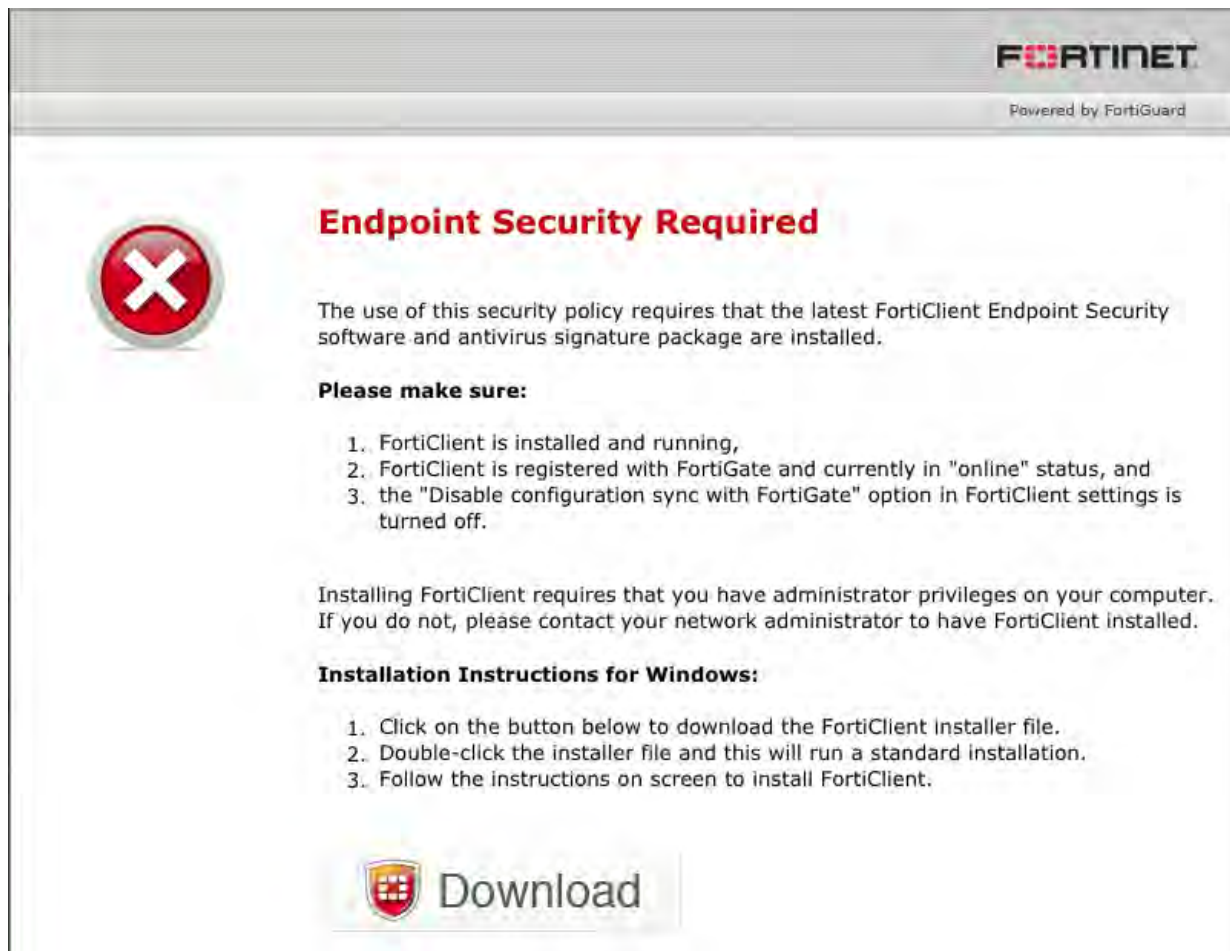

- Create VPN configurations
- Install CA certificates
- Upload logs to FortiAnalyzer or FortiManager
- Enable use of FortiManager for client software/signature update
- Enable a dashboard banner
- Enable client-based logging while on-net
- Output a mobile configuration profile (.mobileconfig file for iOS)

### User experience

When using a web browser, the user of a non-compliant endpoint receives a replacement message HTML page from the FortiGate unit. The message explains that the user needs to install FortiClient Endpoint Security and provides a link to do so. The user cannot continue until the FortiClient software is installed.

For information about modifying the replacement message, see [Modifying the endpoint protection replacement messages on page 2923](#).

## Default FortiClient non-compliance message for Windows

After installing FortiClient Endpoint Security, you will receive an invitation to register with the FortiGate unit. If you accept the invitation, the FortiClient profile is sent to the device's FortiClient application. Now the device is compliant and can connect to the network. FortiClient Endpoint Security registered with a FortiGate unit does not need to be separately licensed with FortiGuard.

The FortiGate unit can also register endpoints connecting over the Internet through a VPN. See [Configuring endpoint registration over a VPN on page 2921](#).

## Licensing and FortiGate endpoint registration limits

To view the number of endpoints that are registered and the total that can be registered, go to **Dashboard**. Under **Licenses**, find **FortiClient**. You will see text like "4 / 10". This means that there are four registered endpoints and a total of ten are allowed.

When the registration limit is reached, the next FortiClient-compatible device will not be able to register with the FortiGate unit. A message appears in the FortiClient application. The FortiClient profile is not sent to client and the client cannot connect through the FortiGate unit.

For all FortiGate models, the maximum number of registered endpoints is ten. For all models except 20C, you can purchase an endpoint license to increase this capacity:

### To add an endpoint license - GUI

1. Go to **Dashboard**.
2. In the **Licenses** widget, click on **FortiClient**, select **Enter License**.
3. Enter the license key in the window that slides in from the right, and select **OK**.

### Maximum registered endpoints with endpoint license

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum ([forum.fortinet.com](http://forum.fortinet.com)). Phone support is only available for paid licenses.

| Model(s)                            | Maximum client limit |
|-------------------------------------|----------------------|
| VM00                                | 200                  |
| FGT/FWF 30 to 90 series             | 200                  |
| FGT 100 to 400 series               | 600                  |
| FGT 500 to 900 series, VM01, VM02   | 2,000                |
| FGT 1000 to 2900 series             | 20,000               |
| FGT 3000 to 3600 series, VM04       | 50,000               |
| FGT 3700D and above, VM08 and above | 100,000              |

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

## Configuring endpoint protection

Endpoint Protection requires that all hosts connecting to an interface have the FortiClient Endpoint Security application installed. Make sure that all endpoints behind the interface are able to install this application. Currently, FortiClient Endpoint Security is available for Microsoft Windows (2000 and later), Apple (Mac OS X and later), and Android devices only.

By default, the FortiGuard service provides the FortiClient installer. If you prefer to host it on your own server, see [Changing the FortiClient installer download location](#), below.

To set up Endpoint Protection, complete the following:

- Create a FortiClient Profile or use the default profile. See [Creating a FortiClient profile on page 2919](#). Enable the application sensor and web category filtering profiles that you want to use.
- Configure the FortiGate unit to support endpoint registration using FortiTelemetry (under **Network > Interfaces**, allow FortiTelemetry admission control).
- Optionally, enforce FortiClient registration. See [Enforcing FortiClient registration on page 2920](#).
- Optionally, configure application sensors and web filter profiles as needed to monitor or block applications.

- Optionally, modify the **Endpoint NAC Download Portal** replacement messages (one per platform). See [Modifying the endpoint protection replacement messages on page 2923](#).

## Creating a FortiClient profile

FortiClient profiles allow you to perform vulnerability scans on endpoints and make sure endpoints are running compliant versions of FortiClient. Also, security posture features cause FortiClient to apply realtime protection, AntiVirus, web filtering, and application control on endpoints.

It is possible for more than one profile to be assigned to a device type. As with security policies, clients are matched to FortiClient profiles in the order that the profiles appear in the list.

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. These enhancements facilitate integration with the Security Fabric.

### To create a FortiClient profile - GUI - FortiOS 5.6.0

1. If you plan to use the Application Firewall feature in the FortiClient profile, go to **Security Profiles > Application Control** to create the Application Sensors that you will need.
2. If you plan to use the Web Category Filtering, go to **Security Profiles > Web Filter** to create the Web Filter Profile that you will need.
3. Go to **Security Profiles > FortiClient Profiles**. If there is only the default FortiClient profile, it will be displayed and ready to edit. At the top right of the page you can select or create other profiles.
4. Select **Create New** or edit an existing profile.
5. In **Assign Profile To**, select the device groups, user groups, and users to which this FortiClient profile applies. ***This is not available for the default profile.***
6. Set the **Endpoint Vulnerability Scan on Client** quarantine level. Similar to FortiOS 5.4, you can set the FortiClient Profile to run the FortiClient vulnerability scanner on endpoints and you can set the vulnerability quarantine level to quarantine endpoints that don't comply. The FortiGate will quarantine a host when a vulnerability with the level of severity selected, or higher, is detected. Options are: **Critical, High, Medium, Low**, and **Information**.
7. **System Compliance** FortiOS 5.6 system compliance settings are similar to those in 5.4 with the addition of a non-compliance action. System compliance checking is performed by FortiClient but the non-compliance action is applied by the FortiGate:
  - select the **Minimum FortiClient version**, if necessary. The lowest supported version is 5.4.1.
  - identify which logs, if any, you will upload to FortiAnalyzer
  - set the **Non-compliance action: Block or Warning**.
8. Under **Security Posture Check**, enable the required options for your network:
  - **Realtime Protection**
  - **Third party AntiVirus on Windows** is required for Windows endpoints
  - identify which logs, if any, you will upload to FortiAnalyzer
  - select whether to enable an **Web Filter** security profile, and / or an **Application Control** sensor.
  - set the **Non-compliance action: Block or Warning**.
9. Select **OK** or **Apply**.

### To create a FortiClient profile - CLI:

This example creates a profile for Windows and Mac computers.

```
config endpoint-control profile
 edit ep-profile1
 set device-groups mac windows-pc
 config forticlient-winmac-settings
 set forticlient-av enable
 set forticlient-wf enable
 set forticlient-wf-profile default
 end
 end
```

## Enforcing FortiClient registration

When you enable FortiTelemetry (formerly known as FortiHeartbeat) on an interface, the option to enforce FortiClient registration becomes available. Devices connecting to that interface are forced to register to the FortiGate and install FortiClient before gaining access to network services.

The following example includes editing the default FortiClient Profile to enforce real time antivirus protection and malicious website blocking.

### To enforce FortiClient registration on the internal interface - GUI:

1. On the FortiGate, go to **System > Feature Visibility** and enable **Endpoint Control**.
2. Go to **Network > Interfaces** and edit the internal interface.
3. Under **Administrative Access**, enable **FortiClient Telemetry**.
4. Under **Admission Control**, enable **Enforce FortiClient Compliance Check**.  
Once this is enabled, you have the option to **Exempt Sources** and/or **Exempt Destinations/Services**. If you were to exempt a source device, that device would not require FortiClient registration to access network services or the Internet.
5. Go to **Security Profiles > FortiClient Profiles**.
6. Under the **Security Posture Check**, enable **Realtime Protection, Up-to-date signatures**.

## Changing the FortiClient installer download location

By default, FortiClient installers are downloaded from the FortiGuard network. You can also host these installers on a server for your users to download. In that case, you must configure FortiOS with this custom download location. For example, to set the download location to a customer web server with address custom.example.com, enter the following command:

```
config endpoint-control settings
 set download-location custom
 set download-custom-link "http://custom.example.com"
end
```

## Storing FortiClient configuration files

Advanced FortiClient configuration files of up to 32k may be stored:

1. Enable the advanced FortiClient configuration option in the endpoint profile:

```
config endpoint-control profile
 edit "default"
 set forticlient-config-deployment enable
 set fct-advanced-cfg enable
 set fct-advanced-cfg-buffer "hello"
 set forticlient-license-timeout 1
```

```

 set netscan-discover-hosts enable
 next
end

```

2. Export the configuration from FortiClient (xml format).
3. Copy the contents of the configuration file and paste in the advanced FortiClient configuration box.

If the configure file is greater than 32k, you need to use the following CLI:

```

config endpoint-control profile
 edit <profile>
 config forticlient-winmac-settings
 config extra-buffer-entries
 edit <entry_id>
 set buffer xxxxxx
 next
 end
 end
 next
end

```

## Blocking access to unsupported FortiClient endpoints

You can use the following command to deny registration of unsupported FortiClient endpoints. An unsupported FortiClient endpoint means the endpoint is running FortiClient but for some reason not all of the criteria are available to identify the endpoint, or the endpoint may be running an unsupported version of FortiClient. Information required that is not available could include the endpoint's IP address or MAC address is not visible.

```

config endpoint-control setting
 set forticlient-dereg-unsupported-client enable
end

```

## Configuring the FortiClient offline grace period

Administrators can configure an offline grace period for registered and offline FortiClients so that PROBE can be processed and, as a result, endpoint compliance is not triggered.

- The grace period is allowed for a client that is compliant, registered, and offline.
- The grace period has a used status which determines if the client is before, during, or after grace period.
- Online and compliant clients will reset the grace status to unused.

### Syntax

```

config endpoint-control settings
 set forticlient-offline-grace {enable | disable}
 set forticlient-offline-grace-interval <seconds> <-- The default is 120
end

```

## Configuring endpoint registration over a VPN

FortiGate units can register FortiClient-equipped endpoints over either an interface-based IPsec VPN or a tunnel-mode SSL VPN. After the user authenticates, the FortiGate unit sends the FortiClient application the IP address and port to be used for registration. If the user accepts the FortiGate invitation to register, registration proceeds and the FortiClient profile is downloaded to the client.

Users without FortiClient Endpoint Security connecting to the SSL VPN through a browser are redirected to a captive portal to download and install the FortiClient software.

## Endpoint registration on an IPsec VPN

You can enable endpoint registration when you configure the FortiClient VPN or you can enable it on an existing FortiClient VPN.

### To enable endpoint registration while configuring the VPN

- Enable **Allow Endpoint Registration** on the Policy & Routing page of the VPN Wizard when creating the FortiClient VPN.

This is only available when **Template Type** is set to **Remote Access** with a FortiClient **Remote Device Type**.

---

### To enable endpoint registration on an existing VPN

1. Go to **Network > Interfaces** and edit the VPN's tunnel interface.  
The tunnel is a virtual interface under the physical network interface.
2. In **Admission Control**, enable **FortiClient Telemetry**.  
Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
3. Select **OK**.

## Endpoint registration on an SSL-VPN

### To enable endpoint registration on the SSL-VPN

1. Go to **VPN > SSL-VPN Settings**.
2. In **Tunnel Mode Client Settings**, make sure **Allow Endpoint Registration** is enabled.
3. Select **Apply**.
4. Go to **Network > Interfaces** and edit the **ssl.root** interface.
5. In **Admission Control**, enable **FortiTelemetry**.  
Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
6. Select **OK**.

This procedure does not include all settings needed to configure a working SSL-VPN.

## Synchronizing endpoint registrations

To support roaming users in a network with multiple FortiGate units, you need to configure synchronization of the endpoint registration databases between the units. The registered endpoints are then recognized on all of the FortiGate units. This is configured in the CLI. For example, to synchronize this FortiGate unit's registered endpoint database with another unit named `other1` at IP address 172.20.120.4, enter:

```
config endpoint-control forticlient-registration-sync
 edit other1
 set peer-ip 172.20.120.4
 end
```

## Modifying the endpoint protection replacement messages

If the security policy has **Redirect all non-compliant/unregistered FortiClient compatible devices to a captive portal** enabled, users of non-compliant devices are redirected to a captive portal that is defined by the **Endpoint NAC Download Portal** replacement message. There are different portals for Android, iOS, Mac, Windows, Quarantine, and “other” devices.

### To modify the the endpoint protection replacement messages

1. Go to **System > Replacement Messages** and select **Extended View**.
2. In the **Endpoint Control** section select the message that you want to edit.  
The replacement message and its HTML code appear in a split screen in the lower half of the page.
3. Modify the text as needed and select **Save**.

## Monitoring endpoints

Go to **Monitor > FortiClient Monitor** to monitor endpoints.

The **Monitor** page allows the user to view FortiClient endpoint devices grouped by interface and then sub-grouped by compliance status. Compliance status can be compliant, non-compliant, exempt, or quarantined.

| Status               | Enforcement Enabled                                                                  | Enforcement Disabled                                                    |
|----------------------|--------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <b>Compliant</b>     | List only active FortiClient endpoints.                                              | No devices listed.                                                      |
| <b>Not-compliant</b> | List devices not-compliant with FortiClient profile, so long as they are not exempt. | No devices listed.                                                      |
| <b>Exempt*</b>       | List FortiClient endpoints exempt from FortiClient compliance.                       | List of all user devices except those quarantined by the administrator. |
| <b>Quarantined</b>   | List devices quarantined by the administrator.                                       | List devices quarantined by the administrator.                          |

\* Includes device exempt reasons as any combination of device, device category/group, and source address.

You can see the reasons for non-compliance by right-clicking on an endpoint in the list.

## Proxy Options

Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out. When a security profile requiring the use of a proxy is enabled in a policy, the **Proxy Options** field is displayed. The Proxy Options define the parameters of how the traffic will be processed and to what level the traffic will be processed. There can be multiple security profiles of a single type. There can also be a number of unique Proxy Option profiles. As the requirements for a policy differ from one policy to the next, a different Proxy Option profile for each individual policy can be configured or one profile can be repeatedly applied.

The **Proxy Options** refer to the handling of the following protocols:

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS

The configuration for each of these protocols is handled separately.

## The use of different proxy profiles and profile options

Just like other components of the FortiGate, different Proxy Option profiles can be configured to allow for granular control of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

## Proxy Options profile components

Highlighted below are certain features available in the **Proxy Options** security profile.

### Log Oversized Files

This setting enables logging of the occurrence of oversized files being processed. It does not change how they are processed. It only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for oversized files and emails is found on the Security Profiles > Proxy Options page under **Common Options**.

### RPC over HTTP

FortiGate units with firmware version 5.4 and higher support RPC over HTTP. This protocol is used by the Microsoft Exchange Server to perform virus scanning of Microsoft Exchange Server email that uses RPC over HTTP. To enable this feature, go to **Security Profiles > Proxy Options** and enable **RPC over HTTP**.

### Protocol Port Mapping

To optimize the resources of the unit, the mapping and inspection of protocols can be enabled or disabled.

Each of the protocols listed in the GUI has a commonly used default TCP port, however, the port used by the protocols can be individually modified. It can also be set to inspect any port with flowing traffic for that particular protocol. The headers of the packets indicate which protocol generated the packet.

## Comfort Clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The **Comfort Clients** feature mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete. The user then knows that processing is taking place and that there hasn't been a failure in the transmission. The slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned and found to be clean of any viruses, the transfer will proceed at full speed.

If there is evidence of an infection, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. A notification that the download has been blocked is displayed. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

## Block Oversized File/Email

This feature is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could overwhelm or exceed the memory of the FortiGate, especially if there were other large files being downloaded at the same time. For this reason, the treatment of large files needs to be addressed.

A threshold is assigned to identify an oversize file or email. This can be set at any size from 1 MB to 10 MB. Any file or email over this threshold will not be processed by policies applying the Antivirus security profile.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

## Chunked Bypass

The HTTP section allows the enabling of **Chunked Bypass**. This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned, enabling this feature means that there is a faster initial response to HTTP requests. From a security stand point, enabling this feature means that the content will not be held in the proxy as an entire file before proceeding.

## Allow Fragmented Messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

## Append Email Signature

The **Append Email Signature** feature ensures that all of the emails going out of a particular network has the appropriate signature or corporate message, for example. These appended emails do not replace existing signatures.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don't print out emails
- For questions regarding the purchasing of our products please call...

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

# SSL/SSH Inspection

Individual deep inspection security profiles can be created depending on the requirements of the policy. Depending on the inspection profile selected, you can:

- Configure which Certificate Authority (CA) certificate will be used to decrypt the Secure Sockets Layer (SSL) encrypted traffic.
- Configure whether a specific SSL protocol will be inspected, blocked or bypassed.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites or website categories will be exempt from SSL inspection
- Identify how to treat invalid, unsupported or untrusted SSL certificates.
- Determine which inspection method will be applied to Secure Shell (SSH) / SSL traffic.

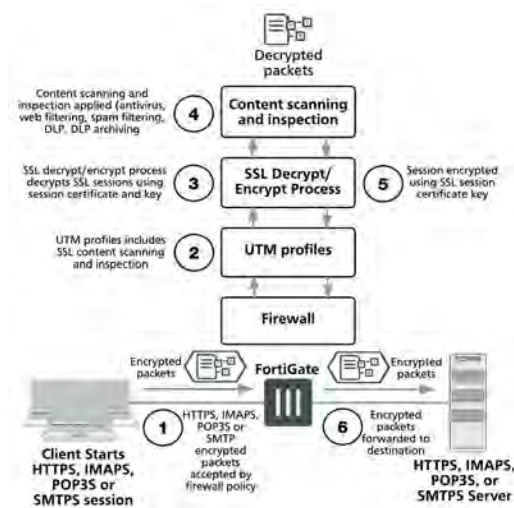

## SSL inspection

Secure Sockets Layer (SSL) content scanning and inspection allows you to apply antivirus scanning, web filtering, FortiGuard Web Filtering, and email filtering to encrypted traffic. To perform SSL content scanning and inspection, the FortiGate unit does the following:

- intercepts and decrypts HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions between clients and servers (FortiGate SSL acceleration speeds up decryption)

- applies content inspection to decrypted content, including:
  - HTTPS, IMAPS, POP3S, and SMTPS Antivirus, DLP, and DLP archiving
  - HTTPS web filtering and FortiGuard web filtering
  - IMAPS, POP3S, and SMTPS email filtering
- encrypts the sessions and forwards them to their destinations.

### FortiGate SSL content scanning and inspection packet flow

### SSL inspection and privacy

Normally, SSL decrypted content is temporarily stored in system memory for content scanning. If Malware is found the infected content is deleted and a message is sent to the destination instead. If no Malware is found the content is re-encrypted and forwarded to its destination. Administrators are not able to access or view the decrypted content.

There are two exceptions that you should be aware of if you have privacy concerns:

- If Sandbox inspection is enabled, either with an on-premises FortiSandbox device or FortiCloud Sandbox, decrypted files can be sent to FortiSandbox or FortiSandbox cloud where they can be viewed by system administrators.
- For flow-based SSL inspection, if SSL mirroring is enabled it is possible to "mirror" or send a copy of the decrypted content to one or more FortiGate interfaces so that the content can be collected by a raw packet capture tool for archiving or analysis. This feature is only available if the inspection mode is set to flow-based.

Decryption, storage, inspection, and use decrypted content is subject to local privacy rules. Use of these features could enable malicious users with administrative access to your FortiGate to harvest sensitive information submitted using an encrypted channel.

For increased privacy of sensitive information, you can use the SSL inspection exemptions feature, described below, to exempt sensitive communication from decryption.

### SSL inspection exemptions

When you are using a browser to visit SSL encrypted sites and are using a certificate that does not match the certificate of the site, you are presented with a warning message and the option of continuing with the untrusted

certificate, or terminating the session. However, there are a number of applications that use SSL encrypted traffic. Some applications will not allow SSL traffic that isn't signed with a trusted certificate. These applications do not necessarily give the option to manually indicate that we trust the certificate or the site. If the option is available, the customer may choose to import needed SSL certificates into Local Certificates and configure a policy for communication for that application.

To assist in preventing loss of access to these sites while still enabling the SSL inspection of the rest of the internet traffic, a method of exempting either web categories or specific sites has been developed. To exempt a large group of sites, the **SSL/SSH Inspection** profile can be configured to exempt FortiGuard Categories. There are three preselected categories due to the high likelihood of issues with associated applications with the type of websites included in these categories.

- Finance and Banking
- Health and Wellness
- Personal Privacy

Other more specific websites can be added to the exemption list by going to **Security Profiles > SSL Inspection**, selecting the appropriate profile, and adding addresses under **Exempt from SSL Inspection**.

When you create a custom web category and tell the inspection profile to exempt that category, you may find some URLs in that category are still inspected. As a best practice, use the [Static URL Filter](#) "Exempt" option instead.

---

Your FortiGate unit has two pre-configured SSL/SSH Inspection profiles that cannot be edited: **certificate-inspection** and **deep-inspection**. You must clone and edit the pre-configured profiles or create a new profile to exempt any additional sites or FortiGuard categories.

### Allow Invalid SSL Certificates

It might seem like a straightforward decision that the allowing of invalid SSL certificates must be bad and, therefore, should not be allowed. However, there can be some reasons that applying this feature should be considered.

At a purely technical level, a properly formed certificate will encrypt the data so that it can only be read by the intended parties and not be read by anyone sniffing traffic on the network. For this reason, people will often use self-signed certificates. These self-signed certificates are free and will encrypt the data just as securely as a purchased certificate. The self-signed certificates, however, are not likely to be recognized by the CA certificate store so will be considered by any checks against that store as invalid.

On the other hand, one of the services the vendors provide is verification of identity of those that purchase their certificates. This means that if you see a valid certificate from a site that identified itself as being from "valid-company.com" that you can be reasonably sure that the site does belong to that company and not a false site masquerading as being part of that company.

You can allow invalid SSL certificates by going to **Security Profiles > SSL Inspection**, selecting the appropriate profile, and enabling **Allow Invalid SSL Certificates**.

During the SSL handshake, a number of checks are made to verify the validity of the certificate.

One source of the checks is against a CA certificate store inside FortiOS. This is the same CA bundle used by the browser Mozilla Firefox.

Updates to the store are:

- With each new version of FortiOS
- Via internal FGD
- Possible with some builds via FTP

Details of the CA certificate store can be found at: <https://curl.haxx.se/docs/caextract.html>

The following checks are made for validity:

| Validity Check                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Signature</b>                                                     | One of the things being checked against the CA bundle is the certificate signature. These signatures are generated via directly signing by the CA's private key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Expiration date</b>                                               | All certificates have an expiry date. The date, based on the devices clock/calendar is compared to the expiry date of the certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Revoked list</b>                                                  | Periodically, certificates are revoked. If a certificate has been revoked it is put on a list. Whenever a certificate is being verified, it is checked against this list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Self signed certificate</b>                                       | In the case of self-signed certificates, the IPS engine and proxy have different handling. IPS engine will keep and use the certificate self-signed certificate, but the public key will be replaced so that SSL inspection can take place. The proxy engine will re-sign the certificate with the untrusted CA certificate. The mechanics are similar but the net effect for the user is similar. The user will get warnings from browsers. The users can choose to remember the self-signed certificate in some browsers, but cannot do the same thing with the certificate re-signed with the untrusted CA.                                                                                                                                                                                                                                                                                                                                |
| <b>Intermediate CA with a weak hash algorithm, such as MD5, SHA1</b> | <p>Some browsers like Chrome or Firefox will give a warning because of a weak signature algorithm (visit <a href="https://sha1-intermediate.badssl.com">https://sha1-intermediate.badssl.com</a> to test).</p> <p>In the IPS Engine, in order to convey the weak intermediate CA back to client, the signature hash algorithm is downgraded in the re-signed server certificate to the weakest algorithm used in the original certificate chain.</p> <p>In the Proxy Engine - In the case of a weak signature algorithm, the Proxy engine will treat the connection as untrusted, and re-sign the server certificate with the untrusted CA. The final user experience is different. Instead of a warning like "NET::ERR_CERT_WEAK_SIGNATURE_ALGORITHM" that you would get in Chrome, you will get a warning that the certificate couldn't be verified (because of the signing CA is not trusted or imported into the user's web browser).</p> |

### Flow-based behaviour

In flow-based mode, a certificate will be considered as **invalid** if it has expired.

In addition, a certificate will be considered as **untrusted** if one or more of the following conditions are met:

- If the chain is broken or incomplete.
- If it is part of the CRL.
- If the CA certificate was not imported to the FortiGate, or it is not in the FortiGate CA certificate store.

## Why use SSL inspection

Most of us are familiar with Hypertext Transfer Protocol Secure (HTTPS) and how it protects a variety of activities on the Internet by applying Secure Sockets Layer (SSL) encryption to the web traffic. However, there are risks associated with its use, since encrypted traffic can be used to get around your network's normal defenses.

For example, you might download a file containing a virus during an e-commerce session. Or you could receive a phishing email containing a seemingly harmless downloader file that, when launched, creates an encrypted session to a command and control (C&C) server and downloads malware onto your computer. Because the sessions in these attacks are encrypted, they might get past your network's security measures.

To protect your network from these threats, SSL inspection is the key your FortiGate uses to unlock encrypted sessions, see into encrypted packets, find threats, and block them. SSL inspection not only protects you from attacks that use HTTPS, but also from other commonly used SSL-encrypted protocols, such as SMTPS, POP3S, IMAPS, and FTPS.

## Full SSL inspection

To make sure that all SSL encrypted content is inspected, you must use full SSL inspection (also known as deep inspection). When full SSL inspection is used, the FortiGate impersonates the recipient of the originating SSL session, then decrypts and inspects the content. The FortiGate then re-encrypts the content, creates a new SSL session between the FortiGate and the recipient by impersonating the sender, and sends the content to the sender.

When the FortiGate re-encrypts the content it uses a certificate stored on the FortiGate. The client must trust this certificate to avoid certificate errors. Whether or not this trust exists depends on the client, which can be the computer's OS, a browser, or some other application, which will likely maintain its own certificate repository. For more information about this, see the recipe [Preventing certificate warnings](#) on the [Fortinet Cookbook](#) site.

There are two deployment methods for full SSL inspection:

### 1. Multiple Clients Connecting to Multiple Servers:

- Uses a CA certificate (which can be uploaded using the **Certificates** menu).
- Typically applied to outbound policies where destinations are unknown (i.e. normal web traffic).
- Address and web category whitelists can be configured to bypass SSL inspection.

### 2. Protecting SSL Server

- Uses a server certificate (which can be uploaded using the **Certificates** menu) to protect a single server.
- Typically used on inbound policies to protect servers available externally through Virtual IPs
- Since this is typically deployed "outside-in" (clients on the Internet accessing server(s) on the internal side of the FortiGate), server certificates using the public FQDN of the server are often purchased from a commercial Certificate Authority and uploaded to the FortiGate. This avoids client applications generating SSL certificate errors due to certificate mismatch.

More detail is available in the Fortinet Knowledge Base. Check these technical notes:

- [How to Enable SSL inspection from the CLI and Apply it to a Policy](#)
- [How to block web-based chat on Gmail webmail using App Sensor + SSL inspection](#)

## SSL certificate inspection

FortiGate also supports a second type of SSL inspection, called SSL certificate inspection. When certificate inspection is used, the FortiGate only inspects the header information of the packets.

Certificate inspection is used to verify the identity of web servers and can be used to make sure that HTTPS protocol isn't used as a workaround to access sites you have blocked using web filtering.

The only security feature that can be applied using SSL certificate inspection mode is web filtering. However, since only the packet is inspected, this method does not introduce certificate errors and can be a useful alternative to full SSL inspection when web filtering is used.

## Troubleshooting

The most common problem with SSL inspection is users receiving SSL errors when the CA certificate is not trusted. This is because by default the FortiGate uses a certificate that is not trusted by the client. There are two ways to fix this:

1. All users must import the FortiGate's default certificate into their client applications as a trusted certificate.
2. Configure the FortiGate to use a certificate that is already trusted by your clients. For example, a certification signed by a CA that your clients already trust.

The first method can be more labor intensive because you have to distribute a certification to all clients. This can also be an ongoing problem as new clients are added to your network. The second method is usually less work but may require paying for a CA. Both of these methods are covered in the recipe [Preventing Certificate Warnings](#).

If you choose to install the certificate on client applications, this can be done with greater ease in a Microsoft Active Directory domain environment by using Group Policy Objects to install the certificate on domain members. Check that the Group Policy has propagated to all computers by opening Internet Explorer on a workstation PC, opening **Tools > Internet Options > Content > Certificates > Trusted Root Certification Authorities**, and ensuring that the FortiGate's certificate is present.

For corporate-owned mobile devices, MDM solutions like AirWatch, MobileIron, or Fiberlink, use Simple Certificate Enrollment Protocol (SCEP) to ease certificate enrollment.

## Best practices

Because all traffic needs to be decrypted, inspected, and re-encrypted, using SSL inspection can reduce overall performance of your FortiGate. To make sure you aren't using too many resources for SSL inspection, do the following:

- **Know your traffic** – Know how much traffic is expected and what percent of the traffic is encrypted. You can also limit the number of policies that allow encrypted traffic.
- **Be selective** – Use white lists or trim your policy to apply SSL inspection only where it is needed.
- **Use hardware acceleration** - FortiGate models with either the CP6 or CPU processor have an SSL/TLS protocol processor for SSL content scanning and SSL acceleration. For more information about this, see the [Hardware Acceleration handbook](#).
- **Test real-world SSL inspection performance yourself** - Use the flexibility of FortiGate's security policy to gradually deploy SSL inspection, rather than enabling it all at once.

## Creating or editing an SSL/SSH Inspection profile

1. Go to **Security Profiles > SSL/SSH Inspection**. This will open to one of the existing profiles. Your FortiGate unit has two pre-configured SSL/SSH Inspection profiles that cannot be edited: certificate-inspection and deep-inspection. You must clone and edit the pre-configured profiles or create a new profile to exempt any additional sites or FortiGuard categories. The links for the actions are located in the upper right hand corner of the window.
  - To view a list of the existing profiles select the List icon (a page) at the far right.
  - To clone an existing profile, select the Clone icon (one page behind another), second from the right
  - To create a new profile, select the Create New icon ("+" symbol), third from the right.
  - To view or edit an existing profile, choose it from the dropdown menu field.
2. **Name Field:**  
Give the profile an easily identifiable name that references its intent.
3. **Comments Field:**  
Enter any additional information that might be needed by administrators, as a reminder of the profile's purpose and scope.
4. **SSL Inspection Options:**
  - a. Enable SSL Inspection of:
    - Multiple Clients Connecting to Multiple Servers - Use this option for generic policies where the destination is unknown.
    - Protecting SSL Server - Use this option when setting up a profile customized for a specific SSL server with a specific certificate.
  - b. Inspection Method  
The options here are:
    - SSL Certificate Inspection - only inspects the certificate, not the contents of the traffic.
    - Full SSL Inspection - inspects all of the traffic.
  - c. CA Certificate  
Use the drop down menu to choose which one of the installed certificates to use for the inspection of the packets or click on **Download Certificate**.
  - d. Untrusted SSL Certificates  
Select an action for untrusted SSL certificates.
  - d. **Protocol Port Mapping** / Inspect All Ports  
Enable the ability to inspect all ports by checking the box. If the feature is not enabled, specify in the field next to the listed protocols, the port through which that protocols traffic will be inspected. Traffic of that protocol going through any other port will not be inspected.

If you select **Inspect All Ports**, then only the IPS engine is used for inspection.

---

5. **Exempt from SSL Inspection:**  
Use the dropdown menus in this section to specify any reputable websites, FortiGuard Web Categories, or addresses will be exempt from SSL inspection.

- Reputable Websites - Enable this option to exempt any websites identified by FortiGuard as reputable.
- Web Categories - By default the categories of Finance and Banking, Health and Wellness, and Personal Privacy, have been added as these are one that are most likely to have applications that will require a specific certificate.
- Addresses - These can be any of the Address objects that have an interface of "Any".
- Log SSL exemptions - Enable this option to log all SSL exemptions

## 6. SSH Inspection Options:

### a. SSH Deep Scan

Toggle to disable or enable the feature

### b. SSH Port

The available options are:

- **Any** - choosing this option will search all of the traffic regardless of service or TCP/IP port for packets that conform to the SSH protocol
- **Specify** - choosing this option will restrict the search for SSH protocol packets to the TCP/IP port number specified in the field. This is not as comprehensive but it is easier on the performance of the firewall.

### d. Protocol Actions

- Exec - Block, Log or neither. Select using check boxes.
- Port-Forward - Block, Log or neither. Select using check boxes.
- SSH-Shell - Block, Log or neither. Select using check boxes.
- X11-Filter - Block, Log or neither. Select using check boxes.

## 6. Common Options:

### a. Allow Invalid SSL Certificates

Check the box to enable the passing of traffic with invalid certificate

### b. Log SSL anomalies

Check the box to allow the Logging function to record traffic sessions containing invalid certificates

The **Full SSL Inspection** method is enabled by default when creating a new SSL/SSH Inspection profile. There are situations where this feature can cause issues so be sure that you would like it enabled before applying the inspection profile.

## Secure white list database

You can enable a feature that gathers a list of reputable domain names that can be excluded from SSL deep inspection. This list is periodically updated and downloaded to FortiGate units through FortiGuard.

Go to **Security Profiles > SSL Inspection**, enable **Exempt from SSL Inspection**, and enable **Reputable Websites**. The reputable websites are rated by FortiGuard. Web Filtering.

### CLI Syntax:

```
config firewall ssl-ssh-profile
 edit deep-inspection
 set whitelist enable
 end
end
```

## SSL server table for SSL offloading

An SSL server table can now be used for SSL offloading. This feature was introduced with the release of FortiOS 5.4.0.

### CLI Syntax

```
config firewall ssl-ssh-profile
 edit <name>
 set use-ssl-server {enable|disable}
 next
end
```

## Custom Application & IPS Signatures

### Creating a custom IPS signature

The FortiGate predefined signatures cover common attacks. If you use an unusual or specialized application or an uncommon platform, add custom signatures based on the security alerts released by the application and platform vendors.

You can add or edit custom signatures using the GUI or the CLI.

#### To create a custom signature

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **[View IPS Signatures]**
3. Select **Create New** to add a new custom signature.
4. Enter a **Name** for the custom signature.
5. Enter the **Signature**. For information about completing this field, see [Custom signature syntax](#) and [Custom signature keywords](#).
6. Select **OK**.

### Custom signature syntax

All custom signatures follow a particular syntax. Each begins with a header and is followed by one or more keywords. A custom signature definition is limited to a maximum length of 512 characters. A definition can be a single line or span multiple lines connected by a backslash (\) at the end of each line.

A custom signature definition begins with a header, followed by a set of keyword/value pairs enclosed by parenthesis [ ( ) ]. The keyword and value pairs are separated by a semi colon (;) and consist of a keyword and a value separated by a space. The basic format of a definition is HEADER (KEYWORD VALUE;)

You can use as many keyword/value pairs as required within the 512 character limit. To configure a custom signature, go to **Security Profiles > Intrusion Prevention**, select **View IPS Signatures**, select **Create New**, and enter the data directly into the **Signature** field, following the guidance in the next topics.

The table below shows the valid characters and basic structure. For details about each keyword and its associated values, see [Custom signature keywords](#).

#### Valid syntax for custom signature fields

| Field  | Valid Characters | Usage                                                                                             |
|--------|------------------|---------------------------------------------------------------------------------------------------|
| HEADER | F-SBID           | The header for an attack definition signature. Each custom signature must begin with this header. |

| Field   | Valid Characters                                                                                                                                                                                                                                                                                                                                             | Usage                                                                  |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| KEYWORD | <p>Each keyword must start with a pair of dashes (--), and consist of a string of 1 to 19 characters.</p> <p>Normally, keywords are an English word or English words connected by an underscore (_). Keywords are case insensitive.</p>                                                                                                                      | The keyword is used to identify a parameter.                           |
| VALUE   | <p>Double quotes (") must be used around the value if it contains a space and/or a semicolon (;).</p> <p>If the value is NULL, the space between the KEYWORD and VALUE can be omitted.</p> <p>Values are case sensitive.</p> <p>Note: If double quotes are used for quoting the value, the double quotes are not considered as part of the value string.</p> | The value is set specifically for a parameter identified by a keyword. |

## Custom signature keywords

- [information](#)
- [session](#)
- [content](#)
- [IP header](#)
- [TCP header](#)
- [UDP header](#)
- [ICMP](#)
- [other](#)

## Information keywords

### [attack\\_id](#)

**Syntax:** --attack\_id <id\_int>;

**Description:**

Use this optional value to identify the signature. It cannot be the same value as any other custom rules. If an attack ID is not specified, the FortiGate automatically assigns an attack ID to the signature. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same attack ID for signatures in different VDOMs.

An attack ID you assign must be between 1000 and 9999.

**Example:** --attack\_id 1234;

## name

**Syntax:** `--name <name_str>;`

**Description:**

Enter the name of the rule. A rule name must be unique. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same rule name for signatures in different VDOMs. The name you assign must be a string greater than 0 and less than 64 characters in length.

**Example:** `--name "Buffer_Overflow";`

## Session keywords

### flow

**Syntax:** `--flow {from_client[,reversed] | from_server[,reversed] | bi_direction};`

**Description:**

Specify the traffic direction and state to be inspected. They can be used for all IP traffic.

**Example:** `--src_port 41523; --flow bi_direction;`

The signature checks traffic to and from port 41523.

If you enable “quarantine attacker”, the optional reversed keyword allows you to change the side of the connection to be quarantined when the signature is detected.

For example, a custom signature written to detect a brute-force log in attack is triggered when “Login Failed” is detected from\_server more than 10 times in 5 seconds. If the attacker is quarantined, it is the server that is quarantined in this instance. Adding reversed corrects this problem and quarantines the actual attacker.

Previous FortiOS versions used to\_client and to\_server values. These are now deprecated, but still function for backwards compatibility.

### service

**Syntax:** `--service {HTTP | TELNET | FTP | DNS | SMTP | POP3 | IMAP | SNMP | RADIUS | LDAP | MSSQL | RPC | SIP | H323 | NBSS | DCERPC | SSH | SSL};`

**Description:**

Specify the protocol type to be inspected. This keyword allows you to specify the traffic type by protocol rather than by port. If the decoder has the capability to identify the protocol on any port, the signature can be used to detect the attack no matter what port the service is running on. Currently, HTTP, SIP, SSL, and SSH protocols can be identified on any port based on the content.

### app\_cat

**Syntax:** `--app_cat <category_int>;`

**Description:**

Specify the category of the application signature. Signatures with this keyword are considered as application rules. These signatures will appear under Application Control instead of IPS configuration. To display a complete list of application signature categories, enter the following CLI commands:

```
config application list
edit default
config entries
edit 1
set category ?
```

## weight

**Syntax:** `--weight <weight_int>;`

### Description:

Specify the weight to be assigned to the signature. This keyword allows a signature with the higher weight to have priority over a signature with a lower weight. This is useful to prioritize between custom and stock signatures and also between different custom signatures.

The weight must be between 0 and 255. Most of the signatures in the Application Control signature database have weights of 10; botnet signatures are set to 250. A range of 20 to 50 is recommended for custom signatures.

## Content keywords

### byte\_extract

**Syntax:** `byte_extract:<bytes_to_extract>, <offset>, <name> \ [, relative][, multiplier <multiplier value>][, <endian>]\ [, string][, hex][, dec][, oct][, align <align value>][, dce];`

### Description:

Use the `byte_extract` option to write rules against length-encoded protocols. This reads some of the bytes from the packet payload and saves it to a variable.

### byte\_jump

**Syntax:** `--byte_jump <bytes_to_convert>, <offset>[, multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct] [, align];`

### Description:

Use the `byte_jump` option to extract a number of bytes from a packet, convert them to their numeric representation, and jump the match reference up that many bytes (for further pattern matching or byte testing). This keyword allows relative pattern matches to take into account numerical values found in network data. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to examine from the packet.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).

- `little`: Process the data as little endian.
- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.
- `align`: Round up the number of converted bytes to the next 32-bit boundary.

### **byte\_test**

**Syntax:** `--byte_test <bytes_to_convert>, <operator>, <value>, <offset> [multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct];`

#### **Description:**

Use the `byte_test` keyword to compare a byte field against a specific value (with operator). This keyword is capable of testing binary values or converting representative byte strings to their binary equivalent and testing them. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to compare.
- `<operator>`: The operation to perform when comparing the value (`<`, `>`, `=`, `!`, `&`).
- `<value>`: The value to compare the converted value against.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.
- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.

### **depth**

**Syntax:** `--depth <depth_int>;`

#### **Description:**

Use the `depth` keyword to search for the contents within the specified number of bytes after the starting point defined by the `offset` keyword. If no offset is specified, the offset is assumed to be equal to 0.

If the value of the `depth` keyword is smaller than the length of the value of the `content` keyword, this signature will never be matched.

The depth must be between 0 and 65535.

### **distance**

**Syntax:** `--distance <dist_int>;`

#### **Description:**

Use the distance keyword to search for the contents within the specified number of bytes relative to the end of the previously matched contents. If the within keyword is not specified, continue looking for a match until the end of the payload.

The distance must be between 0 and 65535.

### content

**Syntax:** `--content [!]"<content_str>"`;

**Description:**

Deprecated, see pattern and context keywords. Use the content keyword to search for the content string in the packet payload. The content string must be enclosed in double quotes.

To have the FortiGate search for a packet that does not contain the specified context string, add an exclamation mark (!) before the content string.

Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character.

The double quote ("), pipe sign(|) and colon(:) characters must be escaped using a back slash if specified in a content string.

If the value of the content keyword is greater than the length of the value of the depth keyword, this signature will never be matched.

### context

**Syntax:** `--context {uri | header | body | host}`;

**Description:**

Specify the protocol field to look for the pattern. If context is not specified for a pattern, the FortiGate unit searches for the pattern anywhere in the packet buffer. The available context variables are:

- **uri:** Search for the pattern in the HTTP URI line.
- **header:** Search for the pattern in HTTP header lines or SMTP/POP3/SMTP control messages.
- **body:** Search for the pattern in HTTP body or SMTP/POP3/SMTP email body.
- **host:** Search for the pattern in HTTP HOST line.

### no\_case

**Syntax:** `--no_case`;

**Description:**

Use the no-case keyword to force the FortiGate unit to perform a case-insensitive pattern match.

### offset

**Syntax:** `--offset <offset_int>`;

**Description:**

Use the offset keyword to look for the contents after the specified number of bytes into the payload. The specified number of bytes is an absolute value in the payload. Follow the offset keyword with the depth

keyword to stop looking for a match after a specified number of bytes. If no depth is specified, the FortiGate unit continues looking for a match until the end of the payload.

The offset must be between 0 and 65535.

### pattern

**Syntax:** `--pattern [!]"<pattern_str>"`;

#### Description:

The FortiGate unit will search for the specified pattern. A pattern keyword normally is followed by a context keyword to define where to look for the pattern in the packet. If a context keyword is not present, the FortiGate unit looks for the pattern anywhere in the packet buffer. To have the FortiGate search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI.

**Example:** `--pattern "/level/" --pattern "|E8 D9FF FFFF|/bin/sh" --pattern  
!"|20|RTSP/"`

### pcre

**Syntax:** `--pcre [!]"<regex>/[ismxAEGRUB]"`;

#### Description:

Similarly to the pattern keyword, use the pcre keyword to specify a pattern using Perl-compatible regular expressions (PCRE). A pcre keyword can be followed by a context keyword to define where to look for the pattern in the packet. If no context keyword is present, the FortiGate unit looks for the pattern anywhere in the packet buffer.

For more information about PCRE syntax, go to <http://www.pcre.org>.

The switches include:

- **i:** Case insensitive.
- **s:** Include newlines in the dot metacharacter.
- **m:** By default, the string is treated as one big line of characters. **^** and **\$** match at the beginning and ending of the string. When **m** is set, **^** and **\$** match immediately following or immediately before any newline in the buffer, as well as the very start and very end of the buffer.
- **x:** White space data characters in the pattern are ignored except when escaped or inside a character class.
- **A:** The pattern must match only at the start of the buffer (same as **^**).
- **E:** Set **\$** to match only at the end of the subject string. Without **E**, **\$** also matches immediately before the final character if it is a newline (but not before any other newlines).
- **G:** Invert the "greediness" of the quantifiers so that they are not greedy by default, but become greedy if followed by **?**.
- **R:** Match relative to the end of the last pattern match. (Similar to `distance:0`).
- **U:** Deprecated, see the context keyword. Match the decoded URI buffers.

### uri

**Syntax:** `--uri [!]"<uri_str>"`;

#### Description:

Deprecated, see pattern and context keywords. Use the uri keyword to search for the URI in the packet payload. The URI must be enclosed in double quotes ("). To have the FortiGate unit search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI. Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character. The double quote ("), pipe sign (|) and colon (:) characters must be escaped using a back slash (\) if specified in a URI string.

### within

**Syntax:** `--within <within_int>;`

**Description:**

Use this together with the distance keyword to search for the contents within the specified number of bytes of the payload.

The within value must be between 0 and 65535.

### IP header keywords

#### dst\_addr

**Syntax:** `--dst_addr [!]<ipv4>;`

**Description:**

Use the dst\_addr keyword to search for the destination IP address. To have the FortiGate search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `dst_addr [172.20.0.0/16, 10.1.0.0/16, 192.168.0.0/16]`

#### ip\_dscp

**Syntax:** `--ip_dscp`

**Description:**

Use the ip\_dscp keyword to check the IP DSCP field for the specified value.

#### ip\_id

**Syntax:** `--ip_id <field_int>;`

**Description:**

Check the IP ID field for the specified value.

#### ip\_option

**Syntax:** `--ip_option {rr | eol | nop | ts | sec | lsrr | ssrr | satid | any};`

**Description:**

Use the ip\_option keyword to check various IP option settings.

The available options include:

- `rr`: Check if IP RR (record route) option is present.
- `eol`: Check if IP EOL (end of list) option is present.
- `nop`: Check if IP NOP (no op) option is present.
- `ts`: Check if IP TS (time stamp) option is present.
- `sec`: Check if IP SEC (IP security) option is present.
- `lsrr`: Check if IP LSRR (loose source routing) option is present.
- `ssrr`: Check if IP SSRR (strict source routing) option is present.
- `satid`: Check if IP SATID (stream identifier) option is present.
- `any`: Check if IP any option is present.

### `ip_tos`

**Syntax:** `--ip_tos <field_int>;`

**Description:**

Check the IP TOS field for the specified value.

### `ip_ttl`

**Syntax:** `--ip_ttl [< | >] <ttl_int>;`

**Description:**

Check the IP time-to-live value against the specified value. Optionally, you can check for an IP time-to-live greater-than (>) or less-than (<) the specified value with the appropriate symbol.

### `protocol`

**Syntax:** `--protocol {<protocol_int> | tcp | udp | icmp};`

**Description:**

Check the IP protocol header.

**Example:** `--protocol tcp;`

### `src_addr`

**Syntax:** `--src_addr [!]<ipv4>;`

**Description:**

Use the `src_addr` keyword to search for the source IP address. To have the FortiGate unit search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

**Example:** `src_addr 192.168.13.0/24`

## TCP header keywords

### `ack`

**Syntax:** `--ack <ack_int>;`

**Description:**

Check for the specified TCP acknowledge number.

### **dst\_port**

**Syntax:** `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

#### **Description:**

Use the `dst_port` keyword to specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

### **seq**

**Syntax:** `--seq [operator,]<number>[,relative];`

#### **Description:**

Check for the specified TCP sequence number.

- `operator` includes `=,<,>,!.`
- `relative` indicates it's relative to the initial sequence number of the TCP session.

### **src\_port**

**Syntax:** `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

#### **Description:**

Use the `src_port` keyword to specify the source port number. You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

### **tcp\_flags**

**Syntax:** `--tcp_flags <SAFRUP120>[!|*|+] [,<SAFRUP120>];`

#### **Description:**

Specify the TCP flags to match in a packet.

- S: Match the SYN flag.
- A: Match the ACK flag.
- F: Match the FIN flag.
- R: Match the RST flag.

- U: Match the URG flag.
- P: Match the PSH flag.
- 1: Match Reserved bit 1.
- 2: Match Reserved bit 2.
- 0: Match No TCP flags set.
- !: Match if the specified bits are not set.
- \*: Match if any of the specified bits are set.
- +: Match on the specified bits, plus any others.

The first part of the value (`<SAFRUP120>`) defines the bits that must be present for a successful match.

**Example:**

`--tcp_flags AP` only matches the case where both A and P bits are set.

The second part (`[ , <SAFRUP120> ]`) is optional, and defines the additional bits that can be present for a match.

For example `tcp_flags S,12` matches the following combinations of flags: S, S and 1, S and 2, S and 1 and 2. The modifiers `!`, `*` and `+` cannot be used in the second part.

## window\_size

**Syntax:** `--window_size [!]<window_int>;`

**Description:**

Check for the specified TCP window size. You can specify the window size as a hexadecimal or decimal integer. A hexadecimal value must be preceded by `0x`. To have the FortiGate search for the absence of the specified window size, add an exclamation mark (`!`) before the window size.

## UDP header keywords

### dst\_port

**Syntax:** `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

**Description:**

Specify the destination port number. You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

### src\_port

**Syntax:** `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

**Description:**

Specify the destination port number. You can specify a single port or port range:

- <port\_int> is a single port.
- :<port\_int> includes the specified port and all lower numbered ports.
- <port\_int>: includes the specified port and all higher numbered ports.
- <port\_int>:<port\_int> includes the two specified ports and all ports in between.

## ICMP keywords

### icmp\_code

**Syntax:** --icmp\_code <code\_int>;

**Description:**

Specify the ICMP code to match.

### icmp\_id

**Syntax:** --icmp\_id <id\_int>;

**Description:**

Check for the specified ICMP ID value.

### icmp\_seq

**Syntax:** --icmp\_seq <seq\_int>;

**Description:**

Check for the specified ICMP sequence value.

### icmp\_type

**Syntax:** --icmp\_type <type\_int>;

**Description:**

Specify the ICMP type to match.

## Other keywords

### data\_size

**Syntax:** --data\_size {<size\_int> | <<size\_int> | >>size\_int};

**Description:**

Test the packet payload size. With data\_size specified, packet reassembly is turned off automatically. So a signature with data\_size and only\_stream values set is wrong.

- <size\_int> is a particular packet size.
- <<size\_int> is a packet smaller than the specified size.
- >>size\_int> is a packet larger than the specified size.

Examples:

- `--data_size 300;`
- `--data_size <300;`
- `--data_size >300;`

### **data\_at**

**Syntax:** `--data_at <offset_int>[, relative];`

**Description:**

Verify that the payload has data at a specified offset, optionally looking for data relative to the end of the previous content match.

### **dump-all-html**

**Syntax:** `--dump-all-html`

**Description:**

Dump all HTML files for benchmarking via iSniff. When there is no file type specified, all HTML files are dumped.

### **rate**

**Syntax:** `--rate <matches_int>,<time_int>;`

**Description:**

Instead of generating log entries every time the signature is detected, use this keyword to generate a log entry only if the signature is detected a specified number of times within a specified time period.

- `<matches_int>` is the number of times a signature must be detected.
- `<time_int>` is the length of time in which the signature must be detected, in seconds.

For example, if a custom signature detects a pattern, a log entry will be created every time the signature is detected. If `--rate 100,10;` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. Use this command with `--track` to further limit log entries to when the specified number of detections occur within a certain time period involving the same source or destination address rather than all addresses.

### **rpc\_num**

**Syntax:** `--rpc_num <app_int>[, <ver_int> | *][, <proc_int> | *];`

**Description:**

Check for RPC application, version, and procedure numbers in SUNRPC CALL requests. The \* wild card can be used for version and procedure numbers.

### **same\_ip**

**Syntax:** `--same_ip;`

**Description:**

Check that the source and the destination have the same IP addresses.

**track**

**Syntax:** `--track {SRC_IP | DST_IP | DHCP_CLIENT | DNS_DOMAIN}[,block_int];`

**Description:**

When used with `--rate`, this keyword narrows the custom signature rate totals to individual addresses.

- `SRC_IP`: tracks the packet's source IP.
- `DST_IP`: tracks the packet's destination IP.
- `DHCP_CLIENT`: tracks the DHCP client's MAC address.
- `DNS_DOMAIN`: counts the number of any specific domain name.
- `block_int` has the FortiGate unit block connections for the specified number of seconds, from the client or to the server, depending on which is specified.

For example, if `--rate 100,10` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. The FortiGate unit maintains a single total, regardless of source and destination address.

If the same custom signature also includes `--track client`; matches are totaled separately for each source address. A log entry is added when the signature is detected 100 times in 10 seconds within traffic from the same source address.

The `--track` keyword can also be used without `--rate`. If an integer is specified, the client or server will be blocked for the specified number of seconds every time the signature is detected.

## Creating a custom signature to block access to example.com

In this first example, you will create a custom signature to block access to the example.com URL.

This example describes the use of the custom signature syntax to block access to a URL. To create the custom signature entry in the FortiGate's GUI, see [Custom Application & IPS Signatures](#).

1. Enter the custom signature basic format.

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID()
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords. Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID(--name "Block.example.com";)
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

Use the `--pattern` keyword to specify what the FortiGate unit will search for:

```
F-SBID(--name "Block.example.com"; --pattern "example.com";)
```

The signature will now detect the example.com URL appearing in network traffic. The custom

signature should only detect the URL in HTTP traffic, however. Any other traffic with the URL should be allowed to pass. For example, an email message to or from example.com should not be stopped.

#### 4. Specify the service

Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

```
F-SBID(--name "Block.example.com"; --pattern "example.com"; --service HTTP;)
```

The FortiGate unit will limit its search for the pattern to the HTTP protocol. Even though the HTTP protocol uses only TCP traffic, the FortiGate will search for HTTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

#### 5. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID(--name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp;)
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

#### 6. Ignore case sensitivity

By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

Use the `--no_case` keyword to make the pattern matching case insensitive.

```
F-SBID(--name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp; --no_case;)
```

Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

#### 7. Limit pattern scans to only traffic sent from the client

The `--flow` command can be used to further limit the network traffic being scanned to only that sent by the client or by the server.

```
F-SBID(--name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp; --no_case; --flow from_client;)
```

Web servers do not contact clients until clients first open a communication session. Therefore, using the `--flow from_client` command will force the FortiGate to ignore all traffic from the server. Since the majority of HTTP traffic flows from the server to the client, this will save considerable system resources and still maintain protection.

#### 8. Specify the context

When the client browser tries to contact example.com, a DNS is first consulted to get the example.com server IP address. The IP address is then specified in the URL field of the HTTP communication. The domain name will still appear in the host field, so this custom signature will not function without the `--context host` keyword/value pair.

```
F-SBID(--name "Block.example.com"; --pattern "example.com"; --service HTTP; --no_
case; --flow from_client; --context host;)
```

## Creating a custom signature to block the SMTP “vrfy” command

The SMTP “vrfy” command can be used to verify the existence of a single email address or to list all of the valid email accounts on an email server. A spammer could potentially use this command to obtain a list of all valid email users and direct spam to their inboxes.

In this example, you will create a custom signature to block the use of the vrfy command. Since the custom signature blocks the vrfy command from coming through the FortiGate unit, the administrator can still use the command on the internal network.

This example describes the use of the custom signature syntax to block the vrfy command. To create the custom signature entry in the FortiGate's GUI, see [Custom Application & IPS Signatures](#).

### 1. Enter the custom signature basic format

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID()
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

### 2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before you add any other keywords.

Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID(--name "Block.SMTP.VRFY.CMD";)
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

### 3. Add a signature pattern

Use the `--pattern` keyword to specify what the FortiGate unit will search for:

```
F-SBID(--name "Block.SMTP.VRFY.CMD"; --pattern "vrfy";)
```

The signature will now detect the vrfy command appearing in network traffic. The custom signature should only detect the command in SMTP traffic, however. Any other traffic with the pattern should be allowed to pass. For example, an email message discussing the vrfy command should not be stopped.

### 4. Specify the service.

Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

```
F-SBID(--name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP;)
```

The FortiGate unit will limit its search for the pattern to the SMTP protocol.

Even though the SMTP protocol uses only TCP traffic, the FortiGate will search for SMTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

### 5. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID(--name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --
protocol tcp;)
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore the pattern in UDP and ICMP network traffic.

#### 6. Ignore case sensitivity.

By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

Use the `--no_case` keyword to make the pattern matching case insensitive.

```
F-SBID(--name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case;)
```

Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

#### 7. Specify the context.

The `SMTP vrfy` command will appear in the SMTP header. The `--context host keyword/value` pair allows you to limit the pattern search to only the header.

```
F-SBID(--name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case; -
-context header;)
```

## Creating a custom signature to block files according to the file's hash value

In this example, you will create a custom signature that allows you to specify a hash value (or checksum) of a file that you want to block. To block multiple files you can create a custom signature for each file with that file's hash value in it and then add all of the custom signatures to an IPS sensor and set the action to block for each one. When IPS encounters a file with a matching hash value the file is blocked.

This example uses a CRC32 checksum of the file as the hash value of the file to be blocked. You can use any utility that supports CRC32 checksums to generate the hash value.

#### 1. Enter the custom signature basic format.

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID()
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

#### 2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords. Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID(--name "File.Hash.Example";)
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic.

#### 3. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID(--name "File.Hash.Example"; --protocol tcp;)
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

**4. Add the CRC32 hash value.**

Use the `--crc32` keyword. This indicates that the value that follows is a hexadecimal number that represents the CRC32 checksum of the file. The `--crc32` keyword also requires that you include the file length. The syntax is `--crc32 <checksum>,<file-length>;`. The following example shows the syntax for a file with checksum 51480492 and file length 822.

```
F-SBID(--name "File.Hash.Example"; --protocol tcp; --crc32 51480492,822;)
```

## Other Security Profiles considerations

The following topics are included in this section:

- [Security Profiles and Virtual domains \(VDOMs\)](#)
- [Conserve mode](#)
- [Using wildcards and Perl regular expressions](#)
- [Adding External Security Devices](#)
- [CPU allocation and tuning commands to survive reboot](#)

### Security Profiles and Virtual domains (VDOMs)

If you enable virtual domains (VDOMs) on your FortiGate unit, any Security Profiles configuration is limited to the VDOM in which you configure it.

While configuration is not shared, the various databases used by Security Profiles features are shared. The FortiGuard antivirus and IPS databases and updates to the databases are shared. The FortiGuard web filter and spam filter features access the FortiGuard distribution network and read the same information when checking email for spam and web site categories and classification.

### Conserve mode

FortiGate units perform all Security Profiles processing in physical RAM. Since each model has a limited amount of memory, conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service. While conserve mode is active, the AV proxy does not accept new sessions.

A warning will appear in the top bar of the FortiGate, regardless of which page in the FortiGate GUI you are on.

#### The AV proxy

Most content inspection the FortiGate unit performs requires that the files, email messages, URLs, and web pages be buffered and examined as a whole. The AV proxy performs this function, and because it may be buffering many files at the same time, it uses a significant amount of memory. Conserve mode is designed to prevent all the component features of the FortiGate unit from trying to use more memory than it has. Because the AV proxy uses so much memory, conserve mode effectively disables it in most circumstances. As a result, the content inspection features that use the AV proxy are also disabled in conserve mode.

All of the Security Profiles features use the AV proxy with the exception of IPS, application control, DoS as well as flow-based antivirus, DLP, and web filter scanning. These features continue to operate normally when the FortiGate unit enters conserve mode.

#### Entering and exiting conserve mode

A FortiGate unit will enter conserve mode because it is nearly out of physical memory, or because the AV proxy has reached the maximum number of sessions it can service. The memory threshold that triggers conserve mode varies by model, but it is about 20% free memory. When memory use rises to the point where less than 20% of the physical memory is free, the FortiGate unit enters conserve mode.

The FortiGate unit will leave conserve mode only when the available physical memory exceeds about 30%. When exiting conserve mode, all new sessions configured to be scanned with features requiring the AV proxy will be scanned as normal, with the exception of a unit configured with the one-shot option.

### Conserve mode effects

What happens when the FortiGate unit enters conserve mode depends on how you have `av-failopen` configured. There are four options:

#### off

The off setting forces the FortiGate unit to stop all traffic that is configured for content inspection by Security Profiles features that use the AV proxy. New sessions are not allowed but current sessions continue to be processed normally unless they request more memory. Sessions requesting more memory are terminated.

For example, if a security policy is configured to use antivirus scanning, the traffic it permits is blocked while in conserve mode. A policy with IPS scanning enabled continues as normal. A policy with both IPS and antivirus scanning is blocked because antivirus scanning requires the AV proxy.

Use the off setting when security is more important than a loss of access while the problem is rectified.

#### pass

The pass setting allows traffic to bypass the AV proxy and continue to its destination. Since the traffic is bypassing the proxy, no Security Profiles scanning that requires the AV proxy is performed. Security Profiles scanning that does not require the AV proxy continues normally.

Use the pass setting when access is more important than security while the problem is rectified.

Pass is the default setting.

#### one-shot

The one-shot setting is similar to pass in that traffic is allowed when conserve mode is active. The difference is that a system configured for one-shot will force new sessions to bypass the AV proxy even after it leaves conserve mode. The FortiGate unit resumes use of the AV proxy only when the `av-failopen` setting is changed or the unit is restarted.

#### idledrop

The idledrop setting will recover memory and session space by terminating all the sessions associated with the host that has the most sessions open. The FortiGate may force this session termination a number of times, until enough memory is available to allow it to leave conserve mode.

The idledrop setting is primarily designed for situations in which malware may continue to open sessions until the AV proxy cannot accept more new sessions, triggering conserve mode. If your FortiGate unit is operating near capacity, this setting could cause the termination of valid sessions. Use this option with caution.

### Configuring the av-failopen command

You can configure the av-failopen command using the CLI.

```
config system global
 set av-failopen {off | pass | one-shot | idledrop}
end
```

The default setting is pass.

## Using wildcards and Perl regular expressions

Many Security Profiles feature list entries can include wildcards or Perl regular expressions.

For more information about using Perl regular expressions, see <http://perldoc.perl.org/perlretut.html>.

### Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (\*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- example.com not only matches example.com but also examplea.com, exampleb.com, examplec.com, and so on.

To add a question mark (?) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (\) to a regular expression from the CLI you must add precede it with another backslash character. For example, `example\\.com`.

To match a special character such as '.' and '\*' use the escape character '\\'. For example:

- To match example.com, the regular expression should be: `example\\.com`

In Perl regular expressions, '\*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- `exam*.com` matches `exammmmm.com` but does not match `example.com`

To match any character 0 or more times, use '.'.\*' where '.' means any character and the '\*' means 0 or more times. For example, the wildcard match pattern `exam*.com` should be `exam.*\\.com`.

### Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression "test" not only matches the word "test" but also any word that contains "test" such as "atest", "mytest", "testimony", "atestb". The notation "\\b" specifies the word boundary. To match exactly the word "test", the expression should be `\\btest\\b`.

### Case sensitivity

Regular expression pattern matching is case sensitive in the web and Email Filter filters. To make a word or phrase case insensitive, use the regular expression `/i`. For example, `/bad language/i` will block all instances of "bad language", regardless of case.

### Perl regular expression formats

The following table lists and describes some example Perl regular expressions.

**Perl regular expression formats**

| Expression        | Matches                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>abc</b>        | "abc" (the exact character sequence, but anywhere in the string)                                                                                              |
| <b>^abc</b>       | "abc" at the beginning of the string                                                                                                                          |
| <b>abc\$</b>      | "abc" at the end of the string                                                                                                                                |
| <b>a b</b>        | Either "a" or "b"                                                                                                                                             |
| <b>^abc abc\$</b> | The string "abc" at the beginning or at the end of the string                                                                                                 |
| <b>ab{2,4}c</b>   | "a" followed by two, three or four "b"s followed by a "c"                                                                                                     |
| <b>ab{2,}c</b>    | "a" followed by at least two "b"s followed by a "c"                                                                                                           |
| <b>ab*c</b>       | "a" followed by any number (zero or more) of "b"s followed by a "c"                                                                                           |
| <b>ab+c</b>       | "a" followed by one or more b's followed by a c                                                                                                               |
| <b>ab?c</b>       | "a" followed by an optional "b" followed by a "c"; that is, either "abc" or "ac"                                                                              |
| <b>a.c</b>        | "a" followed by any single character (not newline) followed by a "c"                                                                                          |
| <b>a\.c</b>       | "a.c" exactly                                                                                                                                                 |
| <b>[abc]</b>      | Any one of "a", "b" and "c"                                                                                                                                   |
| <b>[Aa]bc</b>     | Either of "Abc" and "abc"                                                                                                                                     |
| <b>[abc]+</b>     | Any (nonempty) string of "a"s, "b"s and "c"s (such as "a", "abba", "acbabcacaa")                                                                              |
| <b>[^abc]+</b>    | Any (nonempty) string which does not contain any of "a", "b", and "c" (such as "defg")                                                                        |
| <b>\d\d</b>       | Any two decimal digits, such as 42; same as <code>\d{2}</code>                                                                                                |
| <b>/i</b>         | Makes the pattern case insensitive. For example, <code>/bad language/i</code> blocks any instance of <code>bad language</code> regardless of case.            |
| <b>\w+</b>        | A "word": A nonempty sequence of alphanumeric characters and low lines (underscores), such as <code>foo</code> and <code>12bar8</code> and <code>foo_1</code> |
| <b>100\s*mk</b>   | The strings "100" and "mk" optionally separated by any amount of white space (spaces, tabs, newlines)                                                         |
| <b>abc\b</b>      | "abc" when followed by a word boundary (for example, in "abc!" but not in "abcd")                                                                             |

| Expression    | Matches                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>perl\B</b> | “perl” when not followed by a word boundary (for example, in “perlert” but not in “perl stuff”)                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>\x</b>     | Tells the regular expression parser to ignore white space that is neither preceded by a backslash character nor within a character class. Use this to break up a regular expression into (slightly) more readable parts.                                                                                                                                                                                                                                                                                              |
| <b>/x</b>     | Used to add regular expressions within other text. If the first character in a pattern is forward slash '/', the '/' is treated as the delimiter. The pattern must contain a second '/'. The pattern between '/' will be taken as a regular expressions, and anything after the second '/' will be parsed as a list of regular expression options ('i', 'x', etc). An error occurs if the second '/' is missing. In regular expressions, the leading and trailing space is treated as part of the regular expression. |

## Examples of regular expressions

### Block any word in a phrase

```
/block|any|word/
```

### Block purposely misspelled words

Spammers often insert other characters between the letters of a word to fool spam blocking software.

```
/^.*v.*i.*a.*g.*r.*o.*$/i
/cr[eèèèè][\+|-|=<>\\.\\,;!\\?%&$@\\^°$£€\\{\\}()\\[\\]\\|\\ 01]dit/i
```

## Block common spam phrases

The following phrases are some examples of common phrases found in spam messages.

```
/try it for free/i
/student loans/i
/you're already approved/i
/special[+|--*=<>\\.\\,;!\\?%&~#$@\\^°\\$f€\\{\\} ()\\[\\]\\\\\\\\ 1]offer/i
```

## Adding External Security Devices

(missing or bad snippet)

For more information on this configuration and others, see the *FortiWeb Administration Guide*.

## CPU allocation and tuning commands to survive reboot

CPU affinity, whereby a process will execute on a specific CPU, can be changed so it survives a reboot.

### CLI Syntax:

```
config system global
 set av-affinity
 set ips-affinity
 set miglog-affinity
end
```

**av-affinity:** Affinity setting for AV scanning (64-bit hexadecimal value in the format of xxxxxxxx\_xxxxxxxx).

**ips-affinity:** Affinity setting for IPS (64-bit hexadecimal value in the format of xxxxxxxx\_xxxxxxxx; allowed CPUs must be less than total number of IPS engine daemons). This option is only available if the FortiGate includes NP6 processors and support NTurbo.

**miglog-affinity:** Affinity setting for logging (64-bit hexadecimal value in the format of xxxxxxxx\_xxxxxxxx).

## Excluding industrial IP signatures

To reduce performance impacts caused by industrial IP signatures, the admin can choose to exclude the industrial signatures when they are loaded by IPS; the industrial signatures then become inactive as a result. The following CLI command has been restored for this purpose.

### Syntax

```
config ips global
 set exclude-signatures {none | industrial}
end
```

# Chapter 26 - Server Load Balancing

## Server load balancing

FortiOS server load balancing includes the features you would expect of any server load balancing solution. Traffic can be distributed across multiple backend servers based on multiple methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL or generic TCP/UDP or IP protocols. Session persistence is supported based on the SSL session ID or based on an injected HTTP cookie.

### Before you begin

Before you can configure server load balancing on the GUI go to **System > Feature Visibility** and turn on **Load Balance**. Its in the **Additional Features** list.

To be able to use all of the features described in this chapter you should go to **System > Settings** and setting the **Inspection Mode** to **Proxy**. If **Inspection mode** is set to **Flow-based**, you can only configure Virtual Servers with Type set to HTTP, TCP, UDP, or IP. Proxy mode is required for persistence, HTTP Multiplexing, SSL offloading and other advanced HTTP and SSL features.

### How this chapter is organized

This document contains detailed information about how to configure FortiOS server load balancing to load balance various types of traffic to multiple backend servers. This document describes all server load balancing configuration options and contains detailed configuration examples.

This FortiOS Handbook chapter contains the following sections:

[Inside FortiOS: Server Load Balancing](#) highlights the features and benefits of FortiOS server load balancing.

[Basic load balancing configuration example](#) introduces FortiOS server load balancing by providing a basic configuration example.

[Configuring load balancing](#) describes how to configure FortiOS server load balancing.

[HTTP and HTTPS load balancing, multiplexing, and persistence](#) describes FortiOS server load balancing features that support load balancing HTTP and HTTPS sessions.

[SSL/TLS load balancing](#) describes FortiOS server load balancing features that support load balancing SSL and TLS sessions.

[IP, TCP, and UDP load balancing](#) describes FortiOS server load balancing features that support load balancing IP, TCP, and UDP sessions.

The following configuration examples are also included:

- [Example HTTP load balancing to three real web servers](#)
- [Example Basic IP load balancing configuration](#)
- [Example Adding a server load balance port forwarding virtual IP](#)

- [Example Weighted load balancing configuration](#)
- [Example HTTP and HTTPS persistence configuration](#)

## What's new for server load balancing in FortiOS 5.6.1

The following new server load balancing features are available in FortiOS 5.6.1:

### Add server load balancing real servers on the Virtual Server GUI page (416709)

In previous versions of the FortiOS GUI, after adding a Virtual Server you would go to **Policy & Objects > Real Servers** to add real servers and associate each real server with a virtual server.

In FortiOS 5.6.1 you now go to **Policy & Objects > Virtual Servers**, configure a virtual server and then from the same GUI page add real servers to the virtual server. In addition, on the Virtual Server GUI page the option **Outgoing Interface** is renamed **Interface** and the load balancing method **Source IP Hash** has been renamed **Static**.

## What's new for server load balancing in FortiOS 5.6

The following new server load balancing features are available in FortiOS 5.6:

### IPv6, 6to4, and 4to6 server load balancing (280073)

Sever load balancing is supported for:

- IPv6 VIPs (`config firewall vip6`)
- IPv6 to IPv4 (6to4) VIPs (`config firewall vip64`)
- IPv4 to IPv6 (4to6) VIPs (`config firewall vip46`)

Configuration is the same as IPv4 VIPs, except support for advanced HTTP and SSL related features is not available. IPv6 server load balancing supports all the same server types as IPv4 server load balancing (HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL, TCP, UDP, and IP). IPv4 to IPv6 and IPv6 to IPv4 server load balancing supports fewer server types (HTTP, TCP, UDP, and IP).

### Improved Server load balancing GUI pages (404169)

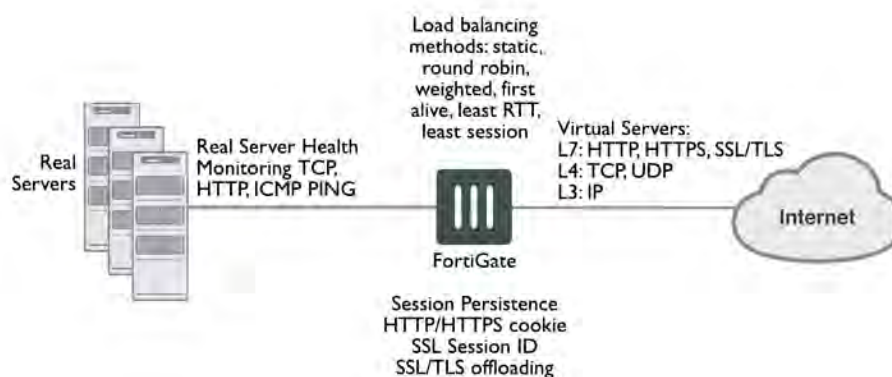

Server load balancing GUI pages have been updated and now include more functionality and input verification.

## Inside FortiOS: Server Load Balancing

Server load balancing distributes workloads across multiple network servers, allowing simultaneous IPv4, IPv6, IPv4 to IPv6 and IPv6 to IPv4 requests to be handled quickly and reliably.

### Server Load Balancing combined with NGFW and UTM protection

By introducing comprehensive server load balancing functionality to Next Generation Firewall (NGFW) and Unified Threat Management (UTM) solutions FortiOS takes threat protection to a whole new level. Rather than going to the expense of deploying multiple solutions to protect your server farm, you can combine firewalling, NGFW, UTM and load balancing into a single FortiGate unit or cluster. The benefit of consolidation is not only limited to cost.

### Key Features & Benefits

|                             |                                                                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Increased resilience</b> | A consolidated solution results in significantly simplified network architecture. High availability can be provided for all technologies with just a pair of devices rather than several. |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Reduced operational overheads**

A unified management solution consisting of a single GUI, logging and reporting, SNMP monitoring and other management functions will significantly reduce the resources required to manage the multiple technology areas. A consolidated solution provides a single point of contact for support and renewals rather than having to deal with multiple vendors.

The FortiOS server load balancing feature set contains all of the features you would expect of a server load balancing solution. Traffic can be balanced across multiple backend servers based on multiple load balancing schedules including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time and number of connections.

The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL/TLS, and generic TCP/UDP and IP protocols. Session persistence is supported based on the SSL session ID, based on an injected HTTP cookie, or based on the HTTP or HTTPS host. SSL/TLS load balancing includes protection from protocol downgrade attacks. Server load balancing is supported on most FortiGate devices and includes up to 10,000 virtual servers on our high end systems.

## SSL/TLS offloading

With more and more critical business applications being made available online and in the cloud, the demand for secure remote continues to increase. While securing web and email applications with SSL/TLS is essential, this protection adds significant performance overheads. An SSL/TLS protected application running on a standard server will perform all the costly encryption/decryption and key exchange routines in software which uses vital CPU resources that should be available for running the application. The consequence of this is that many more or more powerful servers are required to deliver the application.

FortiGate SSL/TLS offloading is designed with the explosion of SSL/TLS applications in mind. The key exchange and encryption/decryption tasks are offloaded to the FortiGate unit where they are accelerated using FortiASIC technology providing significantly more performance than a standard server or load balancer could handle. This frees up valuable resources on the server farm which can be used to run a more responsive business. Server load balancing offloads most SSL/TLS versions including SSL 3.0, TLS 1.0 and TLS 1.2 and supports full mode or half mode SSL offloading with DH key sizes up to 4096 bits.

## SSL/TLS content inspection

Traditionally, SSL encrypted application data would be invisible to any border gateway filtering solution. This is because the encryption process prevents the payload of any connection from being seen other than by the communicating systems. FortiGate SSL Offloading allows the application payload to be inspected before it reaches your servers; preventing intrusion attempts, blocking viruses, stopping unwanted applications, and preventing data leakage. SSL/TLS content inspection supports TLS versions 1.0, 1.1, and 1.2 and SSL versions 1.0, 1.1, 1.2, and 3.0.

## Health Check

Health checking can be enabled to prevent load balancing traffic from being sent to a non-functioning real server. Real server health can be monitored using ICMP ping or more sophisticated TCP testing. The most comprehensive test is HTTP which verifies that the HTTP application is responding and that it is returning the correct content.

Health checking removes real servers from the load balancing cluster which are returning invalid content. The removal of real servers from the clusters is based on the Interval, Timeout and Retry Settings:

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <b>Interval</b> | How often to test the server.                                                           |
| <b>Timeout</b>  | What maximum response time is permissible before a server is treated as non-functional. |
| <b>Retry</b>    | How many failures before the server is considered “dead” and removed from the cluster.  |

## Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

## HTTP Multiplexing

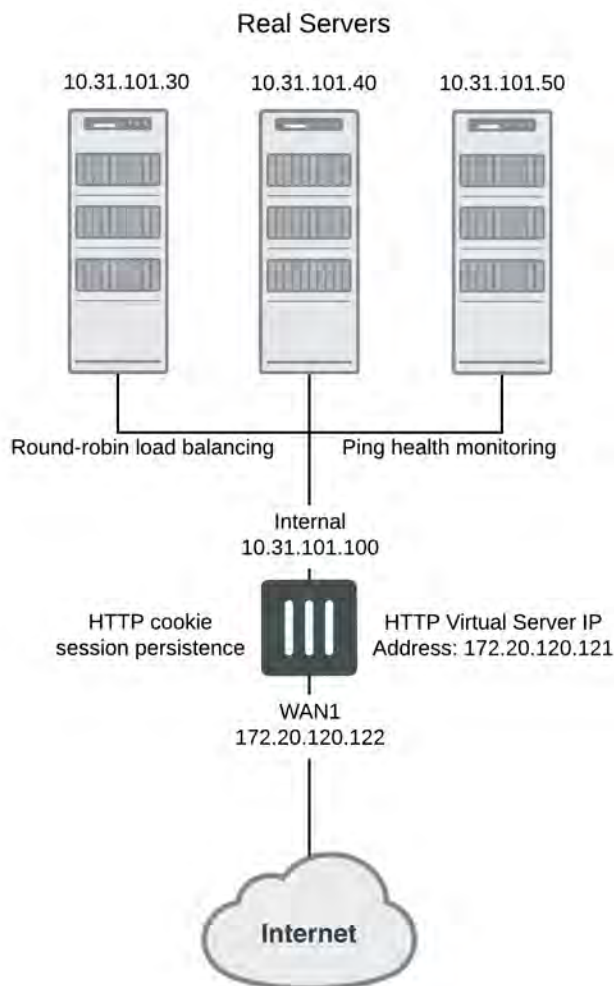

A performance saving feature of HTTP/1.1 compliant web servers is the ability to pipeline requests on the same connection. This allows a single HTTPD process on the server to interleave and server multiple requests. HTTP multiplexing reduces the number idle sessions, too many of which can exhaust the resources on a server. The Fortinet solution has the ability to take multiple separate inbound sessions and multiplex them over the same internal session. This reduces the load on the backend server and increases the overall performance.

## Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown below. In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

### Virtual server and real servers setup

### To configure the example load balancing configuration - general configuration steps

1. Add a load balance ping health check monitor.  
A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Add a load balance virtual server.
3. Add the three load balance real servers to the virtual server.
4. Add a security policy that includes the load balance virtual server as the destination address.

### To configure the example load balancing configuration

1. Go to **Policy & Objects > Health Check** and add the following health check monitor.

|                 |            |
|-----------------|------------|
| <b>Name</b>     | Ping-mon-1 |
| <b>Type</b>     | Ping       |
| <b>Interval</b> | 10 seconds |
| <b>Timeout</b>  | 2 seconds  |
| <b>Retry</b>    | 3          |

2. Go to **Policy & Objects > Virtual Servers** and add a virtual server that accepts the traffic to be load balanced.

|                            |                |
|----------------------------|----------------|
| <b>Name</b>                | Vserver-HTTP-1 |
| <b>Type</b>                | HTTP           |
| <b>Interface</b>           | wan1           |
| <b>Virtual Server IP</b>   | 172.20.120.121 |
| <b>Virtual Server Port</b> | 8080           |
| <b>Load Balance Method</b> | Round Robin    |
| <b>Persistence</b>         | HTTP Cookie    |
| <b>Health Check</b>        | Ping-mon-1     |
| <b>HTTP Multiplexing</b>   | Do not select  |
| <b>Preserve Client IP</b>  | Do not select  |

3. On the same GUI page add the real servers to the virtual server.

|                        |              |
|------------------------|--------------|
| <b>IP Address</b>      | 10.31.101.30 |
| <b>Port</b>            | 80           |
| <b>Max Connections</b> | 0            |
| <b>Mode</b>            | Active       |

|                        |              |
|------------------------|--------------|
| <b>IP Address</b>      | 10.31.101.40 |
| <b>Port</b>            | 80           |
| <b>Max Connections</b> | 0            |
| <b>Mode</b>            | Active       |

|                   |              |
|-------------------|--------------|
| <b>IP Address</b> | 10.31.101.50 |
| <b>Port</b>       | 80           |

|                        |        |
|------------------------|--------|
| <b>Max Connections</b> | 0      |
| <b>Mode</b>            | Active |

- Go to **Policy & Objects > IPv4 Policy** and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

|                           |                                                                |
|---------------------------|----------------------------------------------------------------|
| <b>Name</b>               | Example-policy                                                 |
| <b>Incoming Interface</b> | wan1                                                           |
| <b>Outgoing Interface</b> | internal                                                       |
| <b>Source</b>             | all                                                            |
| <b>Destination</b>        | Vserver-HTTP-1                                                 |
| <b>Schedule</b>           | always                                                         |
| <b>Service</b>            | ALL                                                            |
| <b>Action</b>             | ACCEPT                                                         |
| <b>NAT</b>                | Turn on NAT and select <b>Use Outgoing Interface Address</b> . |
| <b>Antivirus</b>          | Turn on and select an Antivirus profile.                       |

- Select **OK**.

### To configure the example load balancing configuration from the CLI

- Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
edit ping-mon-1
set type ping
set interval 10
set timeout 2
set retry 3
end
```

- Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
edit Vserver-HTTP-1
set type server-load-balance
set server-type http
set ldb-method round-robin
set extip 172.20.120.30
set extintf wan1
set extport 8080
set persistence http-cookie
set monitor tcp-mon-1
config realservers
edit 1
set ip 10.31.101.30
set port 80
```

```
 next
 edit 2
 set ip 10.31.101.40
 set port 80
 end
 edit 3
 set ip 10.31.101.50
 set port 80
 end
 end
end
```

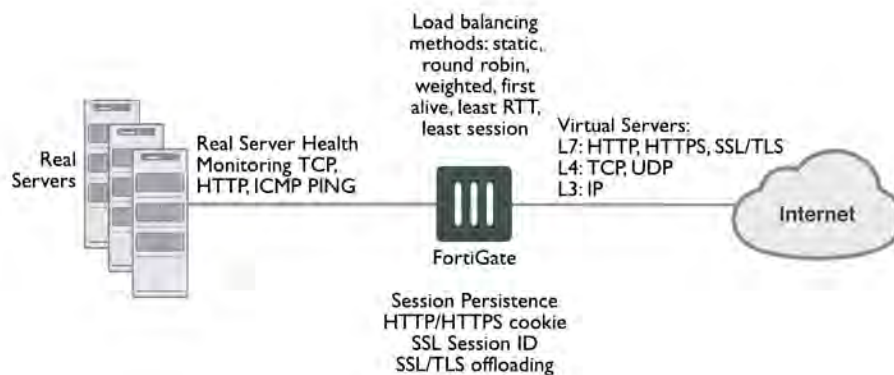

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
 edit 0
 set srcintf wan1
 set srcaddr all
 set dstintf internal
 set dstaddr Vserver-HTTP-1
 set action accept
 set schedule always
 set service ALL
 set nat enable
 set utm-status enable
 set profile-protocol-options default
 set av-profile scan
 end
```

## Configuring load balancing

This section describes how to use the FortiOS server load balancing to load balance traffic to multiple backend servers.

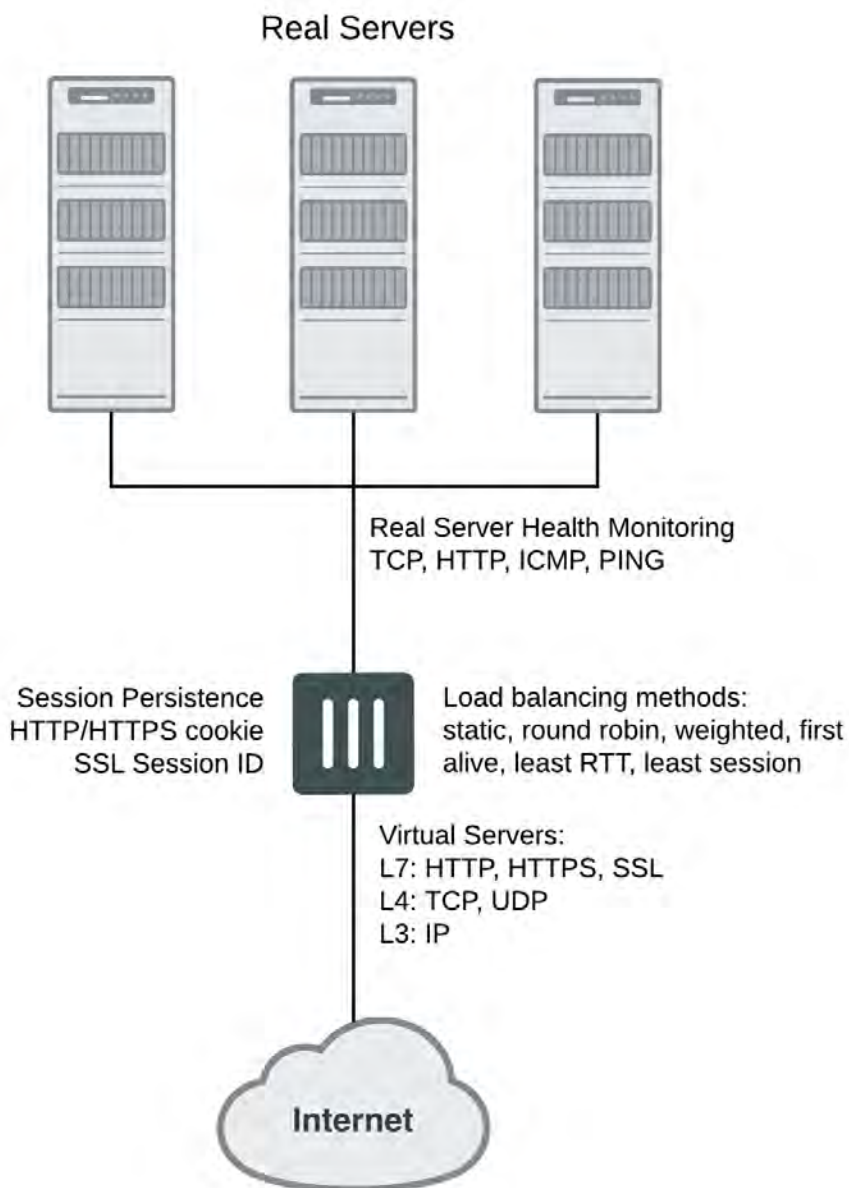

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and distribute it among one or more backend real servers. By doing so, FortiOS enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled by the servers.

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit to cope with the increased load.

**Server load balancing configuration**

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the

virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

## Load balancing and other FortiOS features

Flow-based and proxy-based security features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to load balanced sessions. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication is not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

## Configuring load balancing from the GUI

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the GUI you add load balancing virtual server by going to **Policy & Objects > Virtual Servers**.

You can use the GUI to configure IPv4 server load balancing. To configure IPv6, IPv6 to IPv4, or IPv4 to IPv6 load balancing you need to use the CLI.

### Name

Enter the name for the virtual server.

### Type

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as **IP**, **TCP**, or **UDP** the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as **HTTP**, **HTTPS**, or **SSL** you can apply additional server load balancing features such as **Persistence** and **HTTP Multiplexing**.

- Select **HTTP** to load balance only HTTP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can also select **HTTP Multiplex**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence.
- Select **HTTPS** to load balance only HTTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can also select **Multiplex HTTP requests/responses**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence. You can also set **Persistence** to **SSL Session ID**.
- Select **IMAPS** to load balance only IMAPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **POP3S** to load balance only POP3S sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set **Persistence** to **SSL Session ID**.

- Select **SMTPTS** to load balance only SMTPTS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 465 for SMTPTS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SSL** to load balance only SSL sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **TCP** to load balance only TCP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **UDP** to load balance only UDP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **IP** to load balance all sessions accepted by the security policy that contains this virtual server.

## Interface

Select the virtual server external or outgoing interface from the list. The outgoing interface is connected to the source network and receives the packets to be forwarded to the destination network.

## Virtual Server IP

The IPv4 address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.

## Virtual Server Port

Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.

## Load Balance Method

Select the load balancing method used by the virtual server.

## Persistence

Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. Session persistence is supported for HTTP and SSL sessions.

## Health Check

Select which health check monitor configuration will be used to determine a server's connectivity status.

## HTTP Multiplexing

Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server.

## Preserve Client IP

Select to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

This option appears only if **Type** is set to HTTP or HTTPS.

## SSL Offloading

Accelerate clients' SSL connections to the server by using the FortiGate to perform SSL operations. This option appears only if **Type** is set to one of the SSL protocols.

### Mode

Select which segments of the SSL connection will receive SSL offloading. You can select **Client <-> FortiGate** (or half mode) or **Full** (full mode).

This option appears only if **Type** is set to one of the SSL protocols.

### Certificate

Select the certificate to use with **SSL Offloading**. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

This option appears only if **Type** is set to one of the SSL protocols.

### Real Servers

Add Real Servers to the virtual server. The virtual server load balances traffic to these real servers. See [Real servers on page 2975](#).

## Configuring load balancing from the CLI

From the CLI you configure IPv4 load balancing by adding a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
 edit Vserver-HTTP-1
 set type server-load-balance
 ...
```

Sever load balancing is also supported for:

- IPv6 using the command `config firewall vip6`
- IPv6 to IPv4 using the command `config firewall vip64`
- IPv4 to IPv6 using the commmand `config firewall vip46`

Configuration is the same as IPv4 VIPs except support for advanced HTTP and SSL related features is not available. IPv6 server load balancing supports all the same server types as IPv4 server load balancing (HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL, TCP, UDP, and IP). IPv4 to IPv6 and IPv6 to IPv4 server load balancing supports fewer server types (HTTP, TCP, UDP, and IP).

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server's external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in [RFC 1027](#), so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually

installed on another network. In some cases you may not want the network interface sending ARP replies. You can use the `arp-reply` option to disable sending ARP replies:

```
config firewall vip
 edit Vserver-HTTP-1
 set type server-load-balance
 set arp-reply disable
 ...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

## Load balancing methods
